**Anise** (*Pimpinella Anisum*). *Umbelliferae*. Annual. *Uses*: Leaves as garnish, flavoring, and potherb; seeds and oil for flavoring and perfumery. Propagated by seeds in early spring.  
**Balm** (*Melissa officinalis*). *Labiatae*. Perennial. *Uses*: Foliage for flavoring and salad; oil for perfumery and flavoring beverages. Propagated by divisions, layers, cuttings and seeds.

**Rosemary** (*Rosemarinus officinalis*). *Labiatae*. Perennial. *Uses*: Herbage as seasoning; oil for perfuming soaps and in perfumery. Propagated by cuttings, root division, layers in early spring, and seeds.

**Rue** (*Ruta graveolens*). *Rutaceae*. Perennial. *Uses*: Leaves as seasoning and flavor in beverages; oil for aromatic vinegar and toilet preparations. Propagated by seeds, cuttings, layers or division of tufts.

**Sage** (*Salvia officinalis*). *Labiatae*. Perennial. *Uses*: Leaves for seasoning dressings, sausages, cheese, etc.; oil in perfumery. Propagated by division, layers and cuttings, also seeds.

**Samphire** (*Critium maritimum*). *Umbelliferae*. Perennial. *Uses*: Leaves pickled in vinegar, sometimes with other vegetables. Propagated by seeds in autumn.

**Savory, Summer** (*Satureia hortensis*). *Labiatae*. Annual. *Uses*: Seasoning. Propagated by seeds in spring.

**Savory, Winter** (*Satureia montana*). *Labiatae*. Perennial. *Uses*: Seasoning. Propagated by seeds, cuttings, layers and division.

**Southernwood** (*Artemisia Abrotanum*). *Compositae*. Perennial. *Uses*: Young shoots for flavoring cakes, etc. Propagated by seed; also cuttings in early summer.

**Tansy** (*Tanacetum vulgare*). *Compositae*. Perennial. *Uses*: Seasoning. Propagated by division of clumps, or seeds.

**Tarragon** (*Artemisia Dracunculus*). *Compositae*. Perennial. *Uses*: Herbage in salads and with meats; seasoning; as a decoction in vinegar; oil to perfume soaps, etc. Propagated by cuttings, layers and division.

**Thyme** (*Thymus vulgaris*). *Labiatae*. Perennial. *Uses*: Herbage as seasoning; oil as perfumery; oil-crystals as disinfectant. Propagated by seeds in spring; also cuttings, layers and divisions.

L. H. B.

**CUMIN, or CUMMIN**: The seeds of *Cuminum odorum* (or less properly *C. Cyminum*); black cumin, *Nigella sativa*; sweet cummin, or anise, *Pimpinella Anisum*. See *Culinary Herbs*.

Flowers small, white or purplish, 2-lipped, borne in corymbed cymes or clusters. The genus contains not more than 16 species, 2 N. American, 2 Mexican, and the others S. American. They are somewhat woody, and usually have small lvs.: the whorls of fls. are sometimes loosely corymbose, sometimes axillary, few-fl'd., much shorter than the lvs., sometimes many-fl'd., in dense spikes or terminal heads; calyx 10-13-nerved, 5-toothed; perfect stamens 2.

**mariāna**, Linn. (*C. origanoides*, Brit.). **MARYLAND DITTANY**. **STONE-MINT**. Height 1 ft.: lvs. smooth, ovate, serrate, rounded or heart-shaped at the base, nearly sessile, dotted, 1 in. long; fls. purple-pink in a loose cymose cluster which is terminal. Dry hills, S. N. Y. to Ohio., south to Fla. J.H. III. 35:321. Mn. 7:201. See also *Dittany*.

**CUNNINGHAMIA** (after J. Cunningham, botanical collector, who discovered this conifer in China in 1702). *Pinaceae*. Evergreen trees cultivated for their handsome foliage.

Trunk stout; branches verticillate, spreading, pendulous at the extremities: lvs. linear-lanceolate, rigid, densely spirally arranged and 2-rowed in direction: fls. monœcious; staminate oblong, pistillate globose, both sexes in small clusters at the end of the branches: cones roundish-ovate, 1-2 in. long, with roundish-ovate,

1142. *Cucurbita foetidissima*.

**CUMMINGIA** (for Lady Gordon Cumming) of gardeners (name bestowed by D. Don in 1828), sometimes spelled *Cumingia* (Kunth, 1843), is now referred to *Conanthera*. *Amaryllidaceae*. The *conantheras* are of about four species in Chile, one of which is rarely in cult. as a tender summer-blooming bulb. They are said to be difficult to keep long in cult. They are cormous plants, with basal linear or linear-lanceolate lvs., erect sts. paniculate-branching above, fls. blue on bractless pedicels: perianth funnelform, the tube short; lobes longer than tube, oblong, nearly equal, spreading or becoming reflexed; stamens 6, attached in the throat, shorter than the perianth-lobes, all perfect, the filaments very short; ovary 3-celled, the style subulate. *Conanthera campanulata*, Lindl. (*C. Simsii*, Sweet. *C. bifolia*, Sims, not Ruiz & Pav. *Cummingia campanulata*, D. Don) is 1-1½ ft. high, with linear lvs. shorter than the st. or peduncle and blue paniculate pretty fls. B.M. 2496.

**CUNILA** (origin unknown). *Labiatae*. A low-growing tufted hardy native perennial of this genus is rarely cultivated in borders for its profusion of bloom.

serrate and pointed, coriaceous scales, each with 3 narrow-winged seeds at the base.—Two species, in S. W. China and in Formosa. The species in cult. is a very decorative conifer for warmer temperate regions, much resembling the *Araucaria brasiliensis*. It prefers a half-shaded position and sandy and loamy humid soil. Prop. by seeds or cuttings of half-hardy wood in late summer under glass; short sprouts from the old wood of the trunk or larger branches are the best; cuttings from lateral branches grow into weak and one-sided plants.

**lanceolata**, Hook. (*C. sinensis*, R. Br.). Tree, attaining 80 ft.: lvs. linear-lanceolate, with broad, decurrent base, sharply pointed, finely serrulate, light green and shining above and with 2 broad, whitish bands beneath, 1½-2½ in. long: cones 1-2 in. high. China, cult. in Japan. B.M. 2743. S.Z. 104, 105. R.H. 1903, pp. 549-551. G.W. 13, p. 330; 14, p. 13. J.H. III. 49:447. F. 1854, p. 169.—The second species, *C. Konishii*, Hayata, from Formosa, is not in cult.; it has narrower and much smaller lvs., glaucescent on both sides, and smaller cones; it is very different and forms a transition to *Taiwania*.  
ALFRED REHDER.

**CUNONIA** (named for John Christian Cuno, who catalogued his garden in Amsterdam at the middle of the 18th century). *Cunoniaceae*; formerly included in the *Saxifragaceae*. A half dozen trees or shrubs of the southern hemisphere, one of which is sometimes grown

1143. *Cuphea hyssopifolia*.  
( $\times \frac{1}{2}$ )

Colony, is a large glabrous shrub or tree to 50 ft.: lfts. 2-3 pairs, oblong-lanceolate, sharply serrate; fls. small, very numerous, in opposite racemes, the stamens much exserted. Said to be of easy cult. in a sandy-peaty soil; prop. by cuttings of half-ripened wood. L. H. B.

**CUPANIA:** *Blighia*.

**CÛPHEA** (Greek, *curved*; referring to the prominent protuberance at the base of the calyx-tube). *Lythraceae*. Mostly small greenhouse and conservatory plants.

Plants often clammy: lvs. opposite, rarely whorled or alternate, ovate, lanceolate, or linear, entire: the fls. are often borne in 1-sided racemes, and some of the species have a very odd look from the bold angle made by the slender ascending pedicel and the descending calyx-tube, with an odd projection at the base.—An exceedingly interesting genus of 200 species of tropical and subtropical American herbs and shrubby plants, with remarkable variations in the petals. In *C. ignea*, perhaps the most attractive of the group, the petals are entirely absent, and the showy part is the brilliantly colored calyx-tube. At the other extreme is *C. hyssopifolia* with 6 petals (the normal number in the genus), and all of equal size. Between these two extremes (shown in Figs. 1143 and 1145) are at least two well-marked intermediate types. One of these (exemplified in *C. procumbens*) has 2 large and 4 small petals: the other (*C. Llavea*) has 2 conspicuous petals and the other 4 are completely abortive. These two types are unique among garden plants. The series of intergradient forms is completed by *C. cyanea*, in which there are only 2 petals, and these minute, and *C. micropetala* in which there are 12 barely visible petals, alternating with and shorter than the calyx-teeth. In addition to the species described below, *C. Hookeriana*, Walp., is cult. as *C. Roezlii*, Carr. It has lanceolate lvs., with vermilion and orange calyx. R.H. 1877: 470. According to many American botanists, the correct name for these plants is *Parsonsia*, *Cuphea* applying only to another widely separated genus.

Nearly all cupheas are grown from seed and treated as tender annuals, but *C. ignea* is chiefly propagated by cuttings. They are of easy culture, and the whole series is worth growing.

<i>hyssopifolia</i> , 5.	<i>pinetorum</i> , 4.	

#### A. Petals 6, but very minute and inconspicuous.

1. *micropetala*, HBK. (*C. éminens*, Planch. & Lind.). St. shrubby, more or less branched, 1-2 ft. high: branches and calyx scabrous: lvs. oblong-lanceolate, acute at both ends, but without a distinct petiole, rigid, scabrous: fls. borne singly in succession at a point above the axils, which distinguishes this species from all others here described; petals 6, minute, borne between the calyx-teeth, and shorter than them; calyx 12-toothed, scarlet at the base, yellow towards the top, greenish at the mouth; stamens and filaments red; ovary 2-celled, many-seeded. Mex. HBK. Nov. Gen. Sp. 6, p. 209, t. 551. R.H. 1857, p. 151. F.S. 10:994.—The picture first cited shows a 1-sided raceme, the second a panicle and the third a common raceme. In this species the calyx-tube is the attractive portion, while the petals are inconspicuous. The tube is not 2-lipped, but almost regular. See page 3567.

AA. Petals 6, all conspicuous, but 2 of them much larger than the others.

2. *lanceolata*, Hook. (*C. Zimpánii*, Roetzl). An erect sticky annual, 3-4 ft. high, the branches stout, purplish green: lvs. petiolate, opposite and alternate,  $\frac{3}{4}$ -3 in. long, entire: fls. axillary, solitary, purple or reddish purple, often deflexed; stamens hardly longer than the petals. Sept., Oct. B.M. 6412.—A good, showy herbaceous border plant.

3. *procumbens*, Cav. Annual, herbaceous, 1 ft. high, procumbent, sticky-pubescent, with characteristic purplish hairs: lvs. ovate-lanceolate, with white hairs,  $1\frac{1}{2}$ -3 in. long, gradually decreasing in size until they become bract-like; petiole short: fls. numerous, peduncles longer than the petioles, 2 or 3 times shorter than the calyx; calyx 6-toothed, purplish at the base, green at the tip, with 12 raised streaks, and a pubescence like that of the st.; petals 6, the 2 larger ones on the upper lip of the calyx purple; filaments included. Mex. B.R.

1144. *Cuphea Llavea*.  
(Natural size)

182. *C. purpurea*, Hort. F.S. 4:412. R.B. 22:85, said to be a hybrid between *C. miniata* and *C.*

*viscossima*, is probably not distinct.

4. *pinetorum*, Benth. Perennial and somewhat woody, usually procumbent: lvs. lanceolate, ciliate, 1-2 in. long: fls. purple, the calyx  $\frac{3}{4}$  in. long, colored; stamens 11, the filaments unequal. In sandy plains. Mex.—A useful plant S.

AAA. Petals 6, all of the same size.

5. *hyssopifolia*, HBK. Fig. 1143. St. shrubby: branches numerous, strigose: lvs. lanceolate, rather acute, obtuse at the base, glabrous above, strigose-pilose along the midrib and veins, as may be seen with a hand-lens: fls. with their slender pedicels scarcely longer than the lvs.; calyx glabrous; petals 6, somewhat

unequal, dilute violet; stamens 11, included; filaments villous; ovary 5-6-seeded. Mex.—This is the least attractive of the species here described, and is no longer advertised, but it probably still lingers in conservatories. It is readily distinguished from its showier relatives by its much smaller lvs. (less than  $\frac{1}{2}$  in. long) and much-branched and woody appearance.

1145. *Cuphea ignea*.  
( $\times \frac{1}{2}$ )

Mex. B.R. 32:14 (as *C. strigillosa*, Lindl.) F.S. 1:15 and P.M. 11:241 as *C. strigillosa*, but neither of these plates is the *C. strigillosa*, HBK., which is a different species, with a shrubby st.: branches and calyx clammy-hispid: lvs. ovate-oblong, acute at both ends, clammy, glabrous above, strigose-scabrous below: petals nearly equal; ovary about 8-ovuled.

BB. Size of petals larger, half as long as the calyx or longer.  
c. Calyx 6-toothed.

7. *Llavea*, Lindl. RED-WHITE-AND-BLUE FLOWER. Fig. 1144. Sts. numerous, herbaceous, hispid: branches ascending: lvs. almost sessile, especially near the top, ovate-lanceolate, strigose: racemes short, few-fl.; calyx green on the ventral side, purple on the back and at the oblique-6-toothed mouth; petals 2, large, scarlet, obovate, the other 4 abortive; stamens 11. Guatemala. B.R. 1386. J.H. III. 31:305.—It is doubtful whether the plant described by Lindley is the same as the Mexican plant originally described by Lexarza, which was said to have petals of "dilute scarlet." Lindley's plant had a green calyx, but the plant in the trade is colored. Used for baskets and bedding. Often misspelled *Llavea*.

cc. Calyx 12-toothed.

8. *miniata*, Brongn. St. shrubby, erect: branches few, hispid: lvs. opposite, the upper ones not quite opposite, with a very short petiole, ovate, acute, entire, with white, silky hairs which are denser beneath: fls. solitary, subsessile, axillary, the peduncle adnate to the branch in such a way as to appear between and below the petioles; raceme few-fl., 1-sided. F.S. 2:73. P.M. 14:101. R.H. 1845: 225. R.B. 22:85. Var. *alba*, Hort. A white-fl. variety. Var. *compacta*, Hort. S.H. 2:43. Gt. 46, p. 637.—This is referred to *C. Llavea* of Lexarza, by Index Kewensis. The above description is from the original in F.S. 2:73. Van Houtte describes several hybrid varieties in F.S. 5, p. 487, which differ chiefly in size, color, and marking of petals. Calyx 1 in. long, hispid, green at the base, purple above, 12-toothed at the tip; petals 2, scarlet, wavy. The specific name *miniata* means cinnabar-red, and refers to the petals.

AAAAA. Petals 0.

9. *igneae*, DC. (*C. platycentra*, Hort., not Benth.). Fig. 1145. Branches somewhat angled: lvs. petioled, ovate-lanceolate, acuminate, narrowed at the base, lightly scabrous: fl.-stalks 2-4 times longer than the lf.-stalks: calyx glabrous, shortly 6-toothed, bright

red except at the tip, which has a dark ring and a white mouth; petals 0; stamens 11 or 12, glabrous. Mex. F.S. 2:180. P.M. 13:267.—This is still sold as *C. platycentra*, although De Candolle corrected the error in 1849 (F.S. 5:500 c). This is a remarkable instance of the persistence of erroneous trade names.

WILHELM MILLER.  
N. TAYLOR.†

**CUPRESSUS** (ancient Latin name from Greek, *Kuparissos*). **CYPRESS**. *Pinaceae*. Evergreens, cultivated for their graceful habit and the dark green or glaucous foliage; some are timber trees.

Trees, rarely shrubs, with aromatic evergreen foliage: branchlets quadrangular or nearly so: lvs. opposite, small, scale-like, appressed, minutely denticulate-ciliate, on young seedling plants linear-subulate and spreading: fls. monœcious, minute, solitary on short branchlets; staminate ovate or oblong, yellow; pistillate subglobose: cones globular or nearly so, consisting of 3-7 pairs of ligneous, petate scales, with a mucro or boss on the flattened apex, each bearing many or numerous seeds, but the lower scales usually sterile and smaller; they ripen the second year.—About 12 species in Cent. Amer., north to Calif. and Ariz., and from S. Eu. to S. E. Asia. Monogr. by M. T. Master; in Journ. of Linn. Soc. 31:312-51 (1895). By some botanists, the allied genus *Chamaecyparis* is included.

The cypresses are highly ornamental evergreen trees, greatly varying in habit, hardy only in California and the Gulf states. The hardiest seems to be *C. Macnabiana* and *C. arizonica*, which will stand many degrees of frost in a sheltered position; also *C. macrocarpa*, *C. sempervirens*, *C. funebris* and *C. torulosa* are of greater hardiness than the others. They stand pruning well, and some species are valuable for hedges, *C. macrocarpa* being especially extensively planted for this purpose in California. *C. arizonica* yields excellent timber. The cypresses seem not to be very particular in regard

1146. *Cupressus sempervirens*. Verona.

to soil and situation, but prefer a deep, sandy-loamy soil. For propagation, see *Chamaecyparis*. The young plants should be removed several times in the nursery to secure a firm root-ball; otherwise they will not bear transplanting well.

A. Branches and branchlets erect or spreading; branchlets short and usually rather stout.

B. Cones 1-1½ in. across, with 6-14 scales.

c. Lvs. obtuse; bark scaly.

1. *sempervirens*, Linn. Fig. 1146. Tree, to 80 ft., with erect or horizontal branches and dark green foliage: lvs. closely appressed, ovate, obtuse, glandular: cones oblong or nearly globose; scales 8-14, with a short boss on the back, bract free at the apex. F.S. 7, p. 192. (as *C. torulosa*). S. Eu., W. Asia. Var. *stricta*, Ait. (*C. fastigiata*, DC. *C. Bedfordiana*, Hort.). ITALIAN CYPRESS. With erect branches, forming a narrow, columnar head. The classical cypress of the Greek and Roman writers, much planted in S. Eu. G.W. 9, p. 127. Gn. 33, p. 3 (as *C. stricta*). Var. *cereiformis*, Rehd. (*C. fastigiata cereiformis*, Carr.). A form with very short branches, forming a narrow and slender columnar head. Var. *indica*, Parl. (*C. Roylei*, Carr. *C. Whitleyana*, Hort.). Similar to var. *fastigiata* in habit: cones globose, with 10 scales; bract acutely mucronate at the apex. Var. *horizontalis*, Gord. (*C. horizontalis*, Mill.). Branches horizontally spreading, forming a broad, pyramidal head. The famous avenue of *C. sempervirens* in the Villa Giusti, Verona, Italy, is shown in Fig. 1146 (G.F. 2:464).

2. *macrocarpa*, Hartw. (*C. Hartwegii*, Carr.). MONTEREY CYPRESS. Tree, to 40 ft., occasionally to 70 ft., with horizontal branches, forming a broad, spreading head: branchlets stout: lvs. rhombic-ovate, obtuse, closely appressed, not or obscurely glandular, dark or bright green: cones globular or oblong; scales 8-12, with a short, obtuse boss on the back. Calif., Bay of Monterey. S.S. 10:525. G. 22:30. G.M. 52:952. G.W. 2, p. 497. G.C. III. 18:63; 22:53. Gn. 29, p. 36; 30, p. 189; 38, p. 363; 53, p. 219; 68, p. 237. G.F. 7:245. Var. *Crippsii*, Mast. Lvs. spreading, light glaucous. A juvenile form. Var. *fastigiata*, Knight. Of narrow, pyramidal, fastigiate habit. Var. *Lambertiana*, Mast. (*C. Lambertiana*, Carr.). Dark green form with spreading branches. R.H. 1870, p. 191; 1907, p. 565. Var. *lutea*, Hort., has yellow foliage. Gn. 68, p. 237. J.H.S. 1902, p. 426, fig. 111.

cc. Lvs. acute; bark exfoliating, cherry-like.

3. *guadalupensis*, Wats. (*C. macrocarpa* var. *guadalupensis*, Mast.). Wide-spreading tree, 40 ft. high or more: bark grayish brown, exfoliating, brownish red below: branchlets drooping, slender: lvs. bluish green, scentless, acute or acutish, obscurely glandular: cones globose, 1 in. across or more, with 6-8 very thick strongly bossed scales. Guadalupe Isl. G.C. III. 18:62.

BB. Cones ½-1 in. across, with 6-8 scales.

c. Lvs. distinctly glandular.

4. *Macnabiana*, Murray (*C. glandulosa*, Hook.). Fig. 1147. Shrub with several sts., or small tree, to 20 ft., forming a dense, pyramidal head: lvs. ovate, obtuse,

thickened at the apex, glandular, dark green or glaucous: cones oblong, ¾-1 in. high; scales usually 6, with prominent conical and curved bosses on the back. Calif. S.S. 10:528. R.H. 1870, p. 155. G.C. III. 9:403. F. 1874, p. 88.

cc. Lvs. inconspicuously glandular.

D. The branchlets slender: lvs. green or sometimes glaucous.

5. *Goveniana*, Gord. (*C. californica*, Carr.). Tree, to 50 ft., with slender, erect or spreading branches, forming a broad, open or pyramidal head: branchlets slender: lvs. ovate, acute, closely appressed, inconspicuously glandular: abundant staminate fls. in spring: cones subglobose or oblong; scales 6-8, with short, blunt bosses. Calif. S.S. 10:527. R.H. 1875, p. 108. F. 1876, p. 197. Var. *compacta*, André. Of compact, pyramidal habit. R.H. 1896, p. 9. Var. *glauca*, Carr., with glaucous, and var. *viridis*, Carr., with bright green foliage. Var. *cornuta*, Carr. A form with strongly developed bosses. R.H. 1866, p. 251.

6. *Benthonii*, Endl. (*C. excelsa*, Scott. *C. Karwinskiana*, Regel. *C. thurifera*, Schlecht., not HBK.). Tree, to 70 ft., with horizontal branches, forming a pyramidal head: branchlets slender: lvs. ovate, obtuse or acute, keeled and somewhat thickened at the apex, inconspicuously glandular, bright green: cones globular, ½-¾ in. across; scales 6-8, with short-pointed bosses. Mex. Var. *Lindleyi*, Mast. (*C. Lindleyi*, Klotzsch). Branchlets regularly arranged, of nearly equal length: cones small, with small-pointed bosses. Var. *Knightiana*, Mast. (*C. elegans*, Hort.). Branchlets very regularly arranged, fernlike, drooping, glaucous: cones with stout, conical-pointed bosses. G.C. III. 16:669. *C. Benthonii* has been found in prehistoric asphalt beds at Los Angeles.

DD. The branchlets stout: lvs. glaucous.

7. *arizonica*, Greene (*C. Benthonii* var. *arizonica*, Mast.). Tree, to 40, rarely to 70 ft., with horizontal branches, forming a narrow, pyramidal or broad, open head: branchlets stout: lvs. ovate, obtuse, thickened at the apex, usually without glands, very glaucous: cones subglobose, ¾-1 in. across; scales 6-8, with stout, pointed, often curved bosses. Ariz., Calif. S.S. 10:526. G.C. III. 18:63. I.T. 4:145. M.D. 1904:50.

AA. Branchlets slender, more or less pendulous: lvs. usually acute and keeled, not thickened at the apex: cones about ½ in. or less across (see No. 6).

B. The branchlets not or only slightly compressed.

8. *torulosa*, Don (*C. nepalensis*, Loud.). Tall, pyramidal tree, to 150 ft., with short, horizontal branches, ascending at the extremities: branchlets slender, drooping: lvs. rhombic-ovate, acutish or obtusish, appressed or slightly spreading at the apex, bright or bluish green: cones globular, nearly sessile, ½-¾ in. across; scales 8-10 with a short, obtuse, inconspicuous boss. Himalayas. Gn. 27, p. 39. Var. *Corneyana*, Mast. (*C. Corneyana*, Knight). With distinctly pendulous branches: cones oblong, larger. Var. *ma-*

1147. *Cupressus Macnabiana*.  
(From a cultivated tree.)

*jéstica*, Gord. (*C. majéstica*, Knight). Of more vigorous growth, with drooping branchlets, grayish green.

9. *lusitánica*, Mill. (*C. glauca*, Lam. *C. pëndula*, L'Her. *C. sinënsis*, Hort.). Tree, to 50 ft., with spreading branches and more or less pendulous branchlets; lvs. ovate, acutish, glaucous: cones peduncled, about  $\frac{1}{2}$  in. across, covered with glaucous bloom; scales 6-8, with an elongated, pointed and usually hooked boss. Habitat unknown; cult. in Portugal and naturalized; possibly intro. from India.

BB. *The branchlets distinctly flattened.*

10. *fùnebris*, Endl. (*C. pëndula*, Lambert). Tree, to 60 ft., with wide-spreading, pendulous branches and branchlets, branchlets flattened: lvs. deltoid-ovate, acute, light green, often slightly spreading at the apex: cones short-peduncled, globose,  $\frac{1}{2}$ - $\frac{1}{2}$  in. across; scales 8, with a short-pointed boss. China. G.C. 1850:439. Gn. 28, p. 62. F.S. 6, p. 91.

11. *cashmeriàna*, Royle (*C. torulòsa* var. *kashmiriàna*, Kent. *C. pëndula* var. *glauca*, Nichols.). Tree: branchlets very slender, pendulous, flattened: lvs. rhombic-ovate, spreading at the acute tips, glaucous: cones  $\frac{1}{2}$  in. across. Intro. from Kashmir.

*C. formosënsis*, Henry=Chamæcyparis formosensis.—*C. Lawsoniàna*, Murr.=Chamæcyparis Lawsoniana.—*C. nootkatënsis*, Lambert=Chamæcyparis nootkatensis.—*C. obtusa*, Koch=Chamæcyparis obtusa.—*C. pisifera*, Koch=Chamæcyparis pisifera.—*C. pygmæa*, Sarg. (*C. Goveniana* var. *pygmæa*, Lemm.). Tree, to 30 ft., often fruiting when only 1 or 2 ft. tall: branchlets rather stout: lvs. dark green, without glands: cones ovoid,  $\frac{1}{4}$ - $\frac{3}{4}$  in. long, with 6-10 scales; seeds black. Calif., Mendocino Co. S.S. 14:740.—*C. thurifera*, HBK. Tree with spreading branches: lvs. oblong-lanceolate, upright-spreading, not closely appressed: cones globose, about 1 in. across, with slightly mucronate scales.—*C. thyoides*, Linn.=Chamæcyparis thyoides.

ALFRED REHDER.

**CURATÉLLA** (name refers to the plants being used or worked: used for polishing weapons and metal). *Dilleniaceæ*. Three or 4 S. American and W. Indian small trees or scandent shrubs, of which one is sometimes mentioned in horticultural literature. They are warmhouse evergreens, with white fls. in dense panicles. Sepals and petals 4-5; stamens many; carpels 2 (rarely 1), more or less cohering, follicular. *C. ameri-*

*cana*, Linn., of W. Indies and S. Amer., grows to 10 ft., erect, tortuous: lvs. oval, rough on the upper side, toothed; fls. malodorous, in lateral compound racemes: bark wrinkled and cracked.

**CURCÛLIGO** (Latin, *curculio*, weevil; referring to the beak of the ovary). *Amaryllidacæ*. Warmhouse and conservatory foliage plants with the habit of a young palm and an odd flower-cluster.

Stemless herbs, with short rhizomes, radical long narrow usually plicate lvs., and small fls. in spikes or clusters on short scapes that may be nearly concealed at the base of the plant: perianth 6-parted, the segms. spreading and about equal; stamens 6, attached at the base of the segms.; ovary 3-celled.—The genus is closely related to *Hypoxis*, but differs in its succulent indehiscent fr., and because in many species the ovary has a long beak which looks like a perianth-tube, but this beak is always solid, and bears on its summit the style which is in the center of the perianth.—Twelve species in eastern and western tropics of which *C. recurvata* is grown S. and N., being used by florists for vases, jardinières, and general decorative work, and also used outdoors in summer. It is of easy cult., but requires perfect drainage. It is a question to be determined whether the plants mostly in cult. are *C. recurvata* or *C. latifolia*; the recurved dense ovoid head of fls. quickly distinguishes the former species.

The curculigos are very ornamental plants for large greenhouses, where a high temperature is maintained. To have them looking their best they should, if possible, be planted out in a bed, where they will attain a height of 5 feet. Their gracefully arching leaves are so constructed that they move continually from side to side with the slightest movement of the air. The variety *variegata* is one of the best variegated-leaved plants. While not so robust as the green form, it is more adapted to pot culture. The soil should be two parts loam and another of rotted cow-manure and sand. Drainage must be carefully arranged, as the plants need an abundance of water. The green-leaved kind stands the summers well in the neighborhood of Washington, D. C., if protected from the sun and afforded an abundant supply of water. As house-plants they are likely to suffer for lack of moisture.

Propagation is by division. The pieces, before potting, will make new roots rapidly if placed in the sand-bed of a warm propagating-house for a few days.

*recurvata*, Dry. Height 2½ ft. or more: root tuberos: lvs. from the root, 1-3 ft. long, 2-6 in. wide, with a channeled stalk one-third or one-fourth the length, the blade lanceolate, recurved, plaited: scapes very rarely as long as the lf.-stalks, covered with long, soft brown hairs, recurved at the end, bearing a head of drooping yellow fls., each  $\frac{3}{4}$  in. across; the scape is frequently only 1-3 in. long, the fls. appearing almost on the ground; bracts 1 to each fl. and about as long. Trop. Asia, Austral. B.R. 770. (with scape abnormally long). Var. *striata*, Hort., has a central band of white. Var. *variegata*, Hort., has longitudinal bars of white.

*latifolia*, Dry. Fig. 1148. Height 2-3 ft.: differs from *C. recurvata* in having a very short-stalked erect infl., the bright yellow fls. in a dense cluster near the base of the plant: lvs. lanceolate, 1-2 ft. long and 1-5 in. wide, the petiole 12 in. or less: fr. 1 in. long, club-shaped or pyriform, hairy, with black seeds: the plant produces numerous suckers which, when removed, are easily grown, and bloom in about a year; said to be a beautiful and hardy house-plant, more satisfactory than palms for one without a conservatory. India, Malaysia. B.M. 2034. B.R. 754. L.B.C. 5:443 (as *C. sumatrana*).—Variable in foliage.

G. W. OLIVER.  
WILHELM MILLER.

1148. *Curculigo latifolia*.

XXXII. The Fay currant, one of the large red varieties.

**CURCUMA** (Arabic name). *Zingiberaceae*. Curious and showy warmhouse herbaceous plants with great spikes of large concave or hooded bracts, from which the flowers scarcely protrude.

Erect herbs, the st. rising to 10 ft. from a thick tuberiferous rootstock: lvs. usually large: fls. in a dense cone-

1149. *Curcuma petiolata* leaves. ( $\times \frac{1}{2}$ )

like thyrses, borne behind concave or hooded imbricated obtuse often colored bracts; calyx and corolla tubular, the former 2-3-toothed, the latter dilated above and with 5 ovate or oblong lobes; staminodium petal-like, 3-parted, the middle lobe anther-bearing; fr. inclosed by the bracts. The latest monograph, 1904 (by Schumann in Engler's *Pflanzenreich*, hft. 20), recognizes 42 species, mostly in Trop. Asia and some in Trop. Afr. The fleshy bracts are perhaps the showiest feature of the plant, the topmost ones being colored with gorgeous tropical hues. Rhizomes of some of the species yield East India arrowroot, while others furnish turmeric. The rhizome of *C. zedoaria* of India is very pungent and has properties similar to ginger. The genus is allied to *Alpinia* and *Amomum*.

In spring the tubers should be deprived of last year's mold and repotted in a fresh mixture of light loam, leaf-mold and turfy peat, the pots being well drained, and placed in a warm pit or frame in bottom heat. Water should be given sparingly until after the plant has made some growth. The young roots are soft and succulent, and are likely to rot if the soil remains wet for a long time. After flowering, the leaves soon show signs of decay, and water should be gradually withdrawn. During the resting period the soil should not be allowed to get dust-dry, or the tubers are likely to shrivel. The plants are propagated by dividing the tubers in spring.

**cordata**, Wall. Lvs. 1 ft. long, sheathing, ovate, acuminate, the same color on both sides, obliquely penninerved: bracts in a cylindrical spike, the upper part forming a sterile part called a coma, which is a rich violet, with a large, blood-colored spot: fls. yellow, with a pink hood. Burma. B.M. 4435.—This is now referred to *C. petiolata*, Roxbg., but it seems at least horticulturally distinct, with its rose-pink bracts.

**petiolata**, Roxbg. **QUEEN LILY**. Figs. 1149, 1150. Lvs. 6-8 in. long, peculiar in this genus as being more or less rounded or cordate at the base, the stalk 4-5 in. long: fls. spicate, the spikes 5-6 in. long; bracts 20-30, connate at their bases, and wholly including the pale yellow fls. India. B.M. 5821.—The most beautiful and showiest of the curcumas.

**longa**, Linn. Lvs. 2-2½ ft., the blade about 1 ft. and narrowed at the base: fls. spicate, autumnal. the spikes

4-6 in. long; bracts pale green, not wholly inclosing the pale yellow fls. India. B.R. 886.—The dried rhizomes of this furnish the well-known turmeric of India, used as a condiment and as a dye. Intro. by the Royal Palm Nurseries.

*C. albiflora*, Thwaites, differs from some others here described in having its spikes sunk below the lvs., instead of standing high above the lvs., and all the bracts have fls., while the others have a sterile portion of the spike which is brightly colored. In this species the spike is short and green and the fls. are prominent and white. Ceylon. B.M. 5909.—*C. australasica*, Hook. f., has its upper bracts soft, rosy pink and the fls. pale yellow. Austral. B.M. 5620.—*C. Roscoeana*, Wall., has a long and splendid spike, with bracts gradually changing from green to the vividdest scarlet-orange: fls. pale yellow. Burma. B.M. 4667.—*C. rubescens*, Roxbg. (*C. rubraulis*, Link). Lvs. stalked, oblong, with red sheaths, said to be brown in the center: fls. red. E. Indies.—*C. zedoaria*, Roscoe, has the upper bracts white, tinged with carmine, and handsomely variegated lvs., which, with the green of the lower bracts and the yellow of the fls. makes a striking picture of exotic splendor. Himalayas. B.M. 1546.

WILHELM MILLER.  
N. TAYLOR.†

**CURMÈRIA:** *Homalomena*.

**CURRANT**. The currants grown for their fruit in America are derived mainly from two species, namely, the European red currant, *Ribes vulgare* (*R. rubrum*) (Fig. 1151), and the European black currant, *R. nigrum* (Fig. 1152). There are two promising American species, of which few, if any, improved varieties have been introduced, the swamp red currant (*R. triste*) and the wild black currant (*R. americanum*). Another American species of which at least one named variety has been offered for sale is the Buffalo or Missouri currant (*R. aureum*) (Fig. 1154), also grown because of its ornamental flowers. The currant is not known to have been under cultivation before the middle of the sixteenth century. It is not mentioned by any of the ancient writers who wrote about fruit, and was evidently not known to the Romans.

Currants are natives of comparatively cold or very cold climates; hence most varieties succeed over a very wide area in America. They are among the hardiest of fruits from the standpoint of resistance to cold or changes of temperature, but in hot and dry sections they do not thrive, and, on this account, are unsatisfactory in parts of the southern states.

The currant is not so generally used in America as some other fruits, as few persons care for them when eaten raw, and when cooked they are usually made into jelly and consumed by only a comparatively small proportion of the people. In the coldest parts where other fruits do not succeed well, the currant is more popular, and is used much more generally. It is a wholesome and refreshing fruit and deserves much more attention than it receives at the present time.

The currant does not vary so much when grown from seed as most cultivated fruits, and, being so easily propagated from cuttings, it has not been improved so much as it otherwise would have been. Moreover, size in currants was not of great importance until recent years, when competition in marketing has become keener. It is only during the past fifty or sixty years

1150. *Curcuma petiolata* in flower. ( $\times \frac{1}{6}$ )

that many new varieties have been introduced. At the beginning of the nineteenth century, few named sorts were recognized, the currant being generally known simply under the names black, red and white.

#### *Propagation of currants.*

The usual method of propagating currants is by means of cuttings. These root very readily and good plants are secured after one season's growth. The best time to make the cuttings is in the autumn, as currants begin to grow very early in the spring, and once the buds have swollen they cannot be rooted successfully. Wood of the current season's growth is used. This may be cut early in the autumn as soon as the wood has ripened, from the end of August to the middle of September being the usual time. It should be cut in as long pieces as possible to save time in the field, and put in a cool moist cellar or buried in sand. If the cuttings can be made at once, it is best to do so. These are made by cutting the wood into pieces, each about 8 to 10 inches long, although an inch or two more or less is not of much consequence. The base of the cutting should be made with a square cut just below the last bud. There should be at least  $\frac{1}{2}$  inch of wood left

1151. Common currant—*Ribes vulgare*, in bloom. ( $\times \frac{2}{3}$ )

above the top bud of each cutting, as there should be a strong growth from the upper bud, and if the wood is cut too close it is liable to be weakened. A sloping cut is best for the upper cut, as it will shed rain better, but this is not important. When made, the cuttings should be planted at once, which is usually the best plan, or heeled in. If heeled in, they should be tied in bundles and buried upside down in warm well-drained soil, with about 3 inches of soil over them. The object of burying them upside down is that by this method the bases of the cuttings will be nearer the surface where the soil is warmer and there is more air, and will callus more quickly than if they were further down. The cuttings should callus well in a few weeks, and may then be planted outside, if thought advisable. Cuttings may be kept in good condition over winter by heeling-in

or burying in sand in a cool cellar, or after callusing under a few inches of soil outside, they may be left there over winter if covered with about 4 to 5 more inches of soil to prevent their drying out. Good results are secured with the least trouble by planting the cuttings in nursery rows as soon as they are made. The soil should be well prepared and should be selected where water will not lie. Furrows are opened 3 feet apart and deep enough so that the top bud, or at most two buds, will be above ground. The cuttings are placed about 6 inches apart on the straight side of the furrows and soil thrown in and tramped well about them. When only a smaller number are to be planted a trench may be opened with a spade. It is important to have a large proportion of the cutting below ground, as more roots will be made and the plants will be stronger. There would also be danger of the cuttings drying up before rooting if too much of the wood is exposed. If the season is favorable the cuttings should callus well and even throw out a few roots by winter. Where there is little snow in winter, it is a good practice to cover the tops of the cuttings with about 2 inches of soil, which will be a good protection for them. This soil should be raked off in spring. In the spring, cultivation should be begun early and kept up regularly during the summer to conserve moisture and favor rooting and the development of the bushes. By autumn they should be large enough to transplant to the field.

In Great Britain and Europe, currants are often grown in tree form and are prevented from throwing up shoots from below ground by removing all the buds of the cuttings except the top one before planting in the nursery. This system is not recommended for most parts of America as it has been found by experience that snow breaks down currants grown in this way, and when borers are troublesome it is not wise to depend on one main stem.

Most of the cultivated varieties of currants have originated as natural seedlings, little artificial crossing having been done with this fruit. Currants grow readily from seeds, and it is easy to get new varieties in this way. The seeds are washed out of the ripe fruit, and after drying, may either be sown at once or mixed with sand and kept over winter in a cool dry place and sown very early in the spring. The best plan is to sow them in the autumn in mellow well-prepared and well-drained soil, since when this is done they will germinate very early in the spring, while if sown in the spring the seed may be all summer without sprouting. The seed should not be sown deep, from  $\frac{1}{4}$  to  $\frac{1}{2}$  an inch being quite sufficient. If sown very deep they will not germinate. The young plants may be transplanted from the seed-bed to the open in the autumn of the first year if large enough, but if the plants are very small they may then grow another season, when they should be planted out at least 4 by 5 feet apart, so as to give them room enough to fruit for several seasons, in order that their relative merits may be learned. If intended to remain permanently, the plants should be at least 6 by 5 feet apart. The bushes should begin to bear fruit the second or third year after planting out. Each bush will be a new variety, as cultivated fruits do not come true from seed. If a seedling is considered promising it may be propagated or increased by cuttings, as already described.

#### *The soil and its preparation.*

Currants should be planted in rich soil in order to get the best results. The soil should also be cool, as the currant is a moisture-loving bush. The currant roots near the surface; hence if the soil is hot and dry the crop will suffer. A rich, well-drained clay loam is the best for currants, although they do well in most soils. If the soil is not good, it should receive a good dressing of manure before planting, which should be well worked into the soil, the latter being thoroughly

pulverized before planting is done. A northern exposure is to be preferred, as in such a situation the currants are not likely to suffer in a dry time.

#### *Planting.*

The best time to plant currants is in the autumn. If planted in the spring, they will probably have sprouted somewhat before planting, and on this account their growth the first season will be checked. When the soil is in good condition, currants, especially the black varieties, make strong growth, and the bushes reach a large size; hence it is best to give them plenty of space, as they will do better and are more easily picked than if crowded. Six by 5 feet is a good distance to plant. If planted closer, especially in good soil, the bushes become very crowded before it is time to renew the plantation. Strong one-year-old plants are the best, but two-year-old plants are better than poorly rooted yearlings. It is better to err on the side of planting a little deeper than is necessary than to plant too shallow. A good rule to follow is to set the plants at least an inch deeper than they were in the nursery. The soil should be well tramped about the young plant so that there will be no danger of its drying out. After planting, the soil should be leveled and the surface loosened to help retain moisture.

#### *Cultivation.*

As the currant, to do well, must have a good supply of moisture, cultivation should be begun soon after planting, and the surface soil kept loose during the summer. While the plants are young the cultivation may be fairly deep between the rows, but when the roots begin to extend across the rows, cultivation should be shallow, as many of the roots are quite near the surface.

#### *Fertilizers.*

After the first application of manure, no more should be necessary until the plants begin to fruit, unless other crops are grown between, after which an annual top-dressing of well-rotted barnyard manure is desirable. When only a light application of manure is given, the addition of 200 to 300 pounds to the acre of muriate of potash would be very beneficial. Wood-ashes also would make a good fertilizer with barnyard manure. There is little danger of giving the currant plantation too much fertilizer. Unfortunately, it is usually the other way, this fruit being often very much neglected.

#### *Pruning.*

The black and red currants bear most of their fruit on wood of different ages; hence the pruning of one is a little different from the other. The black currant bears most of its fruit on wood of the previous season's growth, and it is important always to have a plentiful supply of one-year-old healthy wood. The red and white currants produce their fruit on spurs which develop from the wood two or more years of age, and it is important in pruning red and white currants to have a liberal supply of wood two years and older; but, as the fruit on the very old wood is not so good as that on the younger, it is best to depend largely on two- and three-year-old wood to bear the fruit. A little pruning may be necessary at the end of the first season after planting in order to get the bush into shape. From six to eight main stems, or even less, with their side branches, will, when properly distributed, bear a good crop of fruit. Future pruning should be done with the aim of having

from six to eight main branches each season and a few others coming on to take their places. By judicious annual pruning, the bush can be kept sufficiently open to admit light and sunshine. A good rule is not to have any of the branches more than three years of age, since when kept down to this limit the wood will be healthier, stronger growth will be made, and the fruit will be better.

1152. Black currant—*Ribes nigrum*.  
(About natural size.)

#### *When to renew the plantation.*

A currant plantation will bear a great many good crops if well cared for, but if neglected the bushes lose their vigor in a few years. The grower will have to decide by the appearance of the bushes when to renew the plantation; but as a currant plantation can be renewed at comparatively little labor, it is best to have new bushes coming on before the old ones show signs of weakness. At least six good crops may be removed with fair treatment, and ten or more can be obtained if the bushes are in rich soil and well cared for. When one has only a few bushes for home use, they may be reinvigorated by cutting them down to the ground in alternate years, and thus securing a fresh supply of vigorous young wood.

#### *Yield of currants.*

The red currant is one of the most regular in bearing of all fruits, and as it is naturally productive, the average yield should be large. Bailey, in the "Farm and Garden Rule-Book," puts the average yield at 100 bushels per acre. Card, in his book on "Bush-Fruits," says that it ought to be 100 to 150 bushels, "with good care," and reports 320 bushels. At the Central Experimental Farm, Ottawa, Canada, the Red Dutch averaged for four years at the rate of 7,335 pounds to the acre, or over 183 bushels. The largest yield from red currants obtained at the Central Experimental Farm was in 1900, when six bushes of the Red Dutch currant yielded 73 pounds, 15 ounces of fruit. The bushes were 6 by 5 feet apart. This means a yield at the rate of 17,892 pounds to the acre, or, at 40 pounds per bushel, 447 bushels 12 pounds to the acre. The same variety in 1905, in a new plantation, yielded 55½ pounds from six bushes, or at the rate of 13,431 pounds to the acre, or 335 bushels 31 pounds. These are very large yields, and while half of this amount may not be expected in ordinary field culture, the fact that such yields can be produced on a small area should be an inspiration to get more on a larger one.

The average yield of black currants has been somewhat less than the red, although individual yields have been large. The Saunders currant yielded for four years at the rate of 6,534 pounds to the acre, or over 163 bushels; the Kerry at the rate of 6,382 pounds to

the acre, or over 159 bushels. The highest yield of black currants was obtained in 1905, when six bushes of Kerry planted 6 by 5 feet apart, yielded 62 pounds of fruit, or at the rate of 15,004 pounds to the acre, equal to 375 bushels, estimating at 40 pounds to the bushel.

#### Red and white currants.

The red currant makes excellent jelly, and its popularity is largely due to this fact. A large quantity of red currant jelly is made every year in Canada. Red currants are used to a less extent for pies and as jam and are also eaten raw with sugar. As a fruit for eating out-of-hand, the red currant is not very popular, but there are few fruits so refreshing. The white currants are better liked for eating off

the bush than the red, as they are not so acid. The Moore Ruby is a red variety, however, which is milder than most others, and for this reason is better adapted for eating raw. The red currant does not vary so much in quality as the black.

Red currants will remain in condition on the bushes for some time after ripening, and therefore do not have to be picked so promptly as the black.

**Varieties.** Varieties of red currants vary considerably in hardiness, the Cherry, Fay, Comet, Versailles, Wilder and others, while bearing very large fruit, are decidedly more tender than some of the others, hence they should not be planted in the coldest parts. The Franco-German and Prince Albert currants are later than most other varieties, and when it is desired to lengthen the season, these may be planted.

**Varieties of red and white currants recommended:** Red—for general culture—Pomona, Victoria, Cumberland Red, Red Dutch, Long Bunched Holland, Red Grape. Where bushes are protected with snow in winter, and for the milder districts.—Pomona, Victoria, Cumberland Red, Wilder, Cherry, Fay, and Red Cross. White.—White Cherry, Large White, White Grape.

#### Black currants.

There are not so many black currants grown in America as red, but there is a steady demand for them, and it is thought there will be an increasing demand as they become better appreciated. They make excellent jelly and the merits of black currant jam have long been known.

Black currants vary considerably in season, yield and quality, and therefore it is important to know those

that are the best. As most varieties of black currants drop badly from the bushes as soon as ripe, it is important to pick them in good time.

**Varieties of black currants recommended:** Saunders, Collins Prolific, Buddenborg, Victoria, Boskoop Giant. Of those not yet on the market which are considered equal or better than those above, the following are the best: Kerry, Eclipse, Magnus, Clipper, Climax and Eagle, and the Success, for an early variety when yield is not so important as size and quality.

#### Crandall currant.

This is a variety of the Buffalo or Missouri currant (*Ribes odoratum*). A tall, strong, moderately upright grower; moderately productive. Fruit varies in size from small to large, in small, close bunches; bluish black, skin thick; sub-acid with a peculiar flavor. Quality medium. Ripens very unevenly. Season late July to September. As this variety ripens after the others, the birds concentrate on it and get a large proportion of the fruit.

#### Some of the most injurious insects affecting the currant.

**Currant aphid (*Myzus ribis*).** When the leaves of currant bushes are nearly full grown, many of them bear blister-like elevations of a reddish color, beneath which will be found yellowish plant-lice, some winged and some wingless. The blisters are due to the attacks of these insects, and when, as is sometimes the case, they are very abundant, considerable injury is done to the bushes. Spraying forcibly with whale-oil soap, or kerosene emulsion will destroy large numbers of these plant-lice at each application; but the liquid must be copiously applied and driven well up beneath the foliage by means of an angled nozzle. Two or three applications at short intervals may be necessary.

**Currant borer (*Sesia tipuliformis*).** Early in June a beautiful little bluish black fly-like moth, with three bright yellow bands around the body may be seen darting about, around, or at rest on the leaves of currant bushes of all kinds. This is one of the most troublesome enemies of these fruits. The moth lays an egg at a bud on the young wood, and the caterpillar, when hatched, eats its way into the cane and destroys the pith. It remains in the wood during the winter, and the moth emerges during the following summer. Close pruning is the best remedy. Burn the wood.

#### Currant maggot (*Epochra canadensis*).

Red, black and white currants are in some places seriously attacked by the maggots of a small fly. These maggots come to full growth just as the berries are about to ripen, causing them to fall from the bushes, when the insects leave them and burrow into the ground to pupate. Attacked fruit is rendered useless by the presence of the maggots inside the berries; and frequently it is not until the fruit is cooked that

1153. Native black currant—*Ribes floridum*.  
The fruit is immature. ( $\times \frac{1}{2}$ )

1154. Buffalo currant.  
*R. aureum* ( $\times \frac{1}{2}$ )

the white maggots can be detected. Gooseberries are sometimes injured but far less frequently than black and red currants. The only treatment which has given any results is the laborious one of removing about 3 inches of the soil from beneath bushes which are known to have been infested, and replacing this with fresh soil. That which was removed must be treated in some way, so that the contained puparia may be destroyed. This may be done either by throwing it into a pond or by burying it deeply in the earth.

*Currant worm* or *imported currant sawfly* (*Pteronius ribesii*). By far the best known of all the insects that injure currants and gooseberries, is the "currant worm." The black-spotted dark green false caterpillars of this insect may unfortunately be found in almost every plantation of currants or gooseberries, every year in almost all parts of America where these fruits are grown. The white eggs are laid in rows along the ribs of the leaf on the lower side, toward the end of May. From these the young larvæ hatch and soon make their presence known by the small holes they eat through the leaves. Unless promptly destroyed, they will soon strip the bushes of their leaves, thus weakening them considerably so as to prevent the fruit from ripening the first year, and also reducing the quality of the crop of the following season. There are at least two broods in a season in most places; the first appears just as the leaves are attaining full growth, and the second just as the fruit is ripening. The perfect insect is a four-winged fly which may be seen flying about the bushes early in spring. The male is blackish, with yellow legs and of about the same size as a housefly, but with a more slender body. The female is larger and has the body as well as the legs yellow. For the first brood a weak mixture of paris green, one ounce to ten gallons of water, may be sprayed over the bushes, or a dry mixture, one ounce to six pounds of flour, may be dusted over the foliage after a shower or when the leaves are damp with dew. For the second brood paris green must not be used, but white hellebore; or hellebore may be used for first brood, but it is necessary to kill quickly. This is dusted on as a dry powder, or a decoction, one ounce to two gallons of water, may be sprayed over the bushes. It is, of course, far better to treat the first brood thoroughly, to reduce the number of females which lay eggs for the second brood.

1155.  
Currant  
cutting.

*Oyster-shell scale* (*Lepidosaphes ulmi*). Several kinds of scale insects attack currants. These plants seem to be particularly susceptible to the attacks of the well-known oyster-shell scale of the apple, and the San José scale. In neglected plantations these injurious insects increase rapidly, and a great deal of injury results to the bushes. The remedies for scale insects are direct treatment for the destruction of the infesting insect, and preventive measures, such as the invigoration of the bush by special culture and pruning, to enable it to throw off or outgrow injury. Infested plantations should be cultivated and fertilized early in the season, and all unnecessary wood

1156. To illustrate the pruning of a currant bush. The old cane, a, is to be cut away. The straight new canes at left are to remain.

should be pruned out. As direct remedies, spraying the bushes at the time the young scale insects first appear in June with kerosene emulsion or whale-oil soap, or spraying in autumn before the hard weather of winter sets in with a simple whitewash made with one pound of lime in each gallon of water, give the best results. Two coats of the whitewash should be applied, the second one immediately after the first is dry. In putting on two thin coats of the wash instead of one thick one, far better results have been secured.

For the San José scale, the lime-and-sulfur wash is necessary, and must be repeated every year.

#### *Diseases of the currant.*

The currant is affected by very few diseases. The only ones that do much injury are the following:

*Leaf-spot, rust* (*Septoria ribis*). The leaf-spot fungus affects black, red and white currants, causing the leaves to fall prematurely, and thus weakening the bushes. This disease is first noticed about mid-summer, when small brownish spots appear on the leaves. These often become so numerous that they affect a large part of the foliage, soon causing the leaves to fall. As the disease often appears before the fruit is picked, it is difficult to control it if the bushes are not sprayed previously. By using the ammoniacal copper carbonate the bushes may be sprayed a week or two before it is expected, without discoloring the fruit, giving a second application, if necessary. As soon as the fruit is picked, the bushes should be thoroughly sprayed with bordeaux mixture. Experiments have shown that this disease can be controlled by spraying.

*Currant anthracnose* (*Gloeosporium ribis*). This disease, which may be mistaken for the leaf-spot, affects different parts of the bush, including the leaves, leaf-stalks, young branches, fruit and fruit-stalks. On the leaves it is made evident during the month of June by the small brown spots which are usually smaller than those made by the leaf-spot fungus. The lower leaves are affected first, and finally the upper ones. They turn yellow and gradually fall to the ground, and when the disease is bad the bushes are defoliated before their time. On the petioles or leaf-stalks, the disease causes slightly sunken spots. The fruit is affected with roundish black spots which are more easily seen when the fruit is green. On the young wood the diseased areas are light in color and are not so noticeable. The wood is not nearly so much injured by the disease as the leaves. The spores which spread this disease are formed in pustules, the majority of which are under the upper epidermis of the leaf. Where the spores are to appear, the surface of the leaf is raised and blackened

1157. Tree-form training of currant.

in spots looking like small pimples. When the spores are ready to come out the skin breaks and they escape and re-infect other parts. When the foliage drops early on account of this disease the fruit is liable to be scalded by the sun. The fruit may also wither before ripening properly, owing to lack of food or of moisture, as, the leaves having fallen, they are unable to keep up the necessary supply. The premature falling of the leaves prevents the buds from maturing properly, hence they are not in so good condition to bear fruit the next year. Spraying with bordeaux mixture is recommended as an aid in controlling this disease. It would be wise, when currant anthracnose is troublesome, to spray the bushes thoroughly before the leaves appear. A second spraying should be made when the leaves are unfolding, and successive sprayings at intervals of ten to fourteen days until the fruit is nearly full grown, and there is danger of its being discolored by the spray when ripe. Paris green should be added to the mixture when the first brood of the currant worm appears. A thorough spraying after the fruit is harvested is desirable.

W. T. MACOUN.

**CŪSCUTA** (origin of name obscure). *Convolvulaceæ*. **DODDER.** Degenerate parasitic twiners, bearing clusters of small flowers. They are leafless annuals, with very slender yellow, white, or red stems, which become attached to the host-plant by means of root-like suckers. The seeds fall to the ground and germinate in

1158. Dodder, twining on its host.—*Cuscuta Gronovii*.

the spring.—Species 100, widely distributed. As soon as the young shoot reaches an acceptable host, the root dies and the plant becomes parasitic. Failing to find a host, the plant dies. Dodders are common in low, weedy places. Some species are also serious pests, as the clover dodder, alfalfa dodder, and flax dodder. One of the common species (*C. Gronovii*, Willd.), of low grounds, is shown in Fig. 1158.

**CUSHAW:** *Cucurbita moschata*.

**CUSTARD APPLE:** *Annona*.

#### CUT-FLOWER INDUSTRY IN NORTH AMERICA.

The feature that most distinguishes American floriculture from that of Europe is the great preponderance of the cut-flower trade as compared with the sales of plants. Forty years ago the passion of Americans for cut-flowers was remarked by travelers, but however

important the cut-flower trade may then have appeared it has had a marvelous growth since that time. Prior to the Civil War it would have been impossible to purchase any considerable quantity of cut-flowers in the winter season in any of the large cities. The green-houses were small flue-heated structures in which a great variety of plants was grown; hence it would have been impossible to secure a quantity of any one kind. There were no middlemen to collect even the small quantities produced in a locality, and when large numbers of blooms were required, advance notice was expected and the person wishing the flowers had to do the collecting from the various establishments. After the period mentioned, floricultural establishments rapidly increased in number and size. This growth has continued until today. Instead of being concentrated about large cities, there is scarcely a city of 5,000 or even less that does not have its florist. Not less than \$100,000,000 is now invested in the cultivation and sale of cut-flowers in America. Although statistics of the cut-flowers alone are not available, a conservative estimate based on the United States census of 1910 places their annual value at \$25,000,000.

From forty to sixty years ago the camellia was the most valued cut-flower, either for personal adornment or for bouquets, and sometimes as much as \$1, \$2 and even \$3 were obtained for single flowers at the height of the holiday season. Then came a period of decline during which they were almost forgotten except in a few private collections, but now they are seen upon the market as pot-plants. The florist of the present generation wonders how they could have been admired to the extent that they should lead as cut-flowers. Perhaps no better idea of the requirements of the former cut-flower trade can be given than to quote the record of a leading New York florist establishment for 1867 which shows a product as follows: Camellias about 45,000, bouvardias 20,000, carnations 70,000, double primroses 100,000, and tuberose 50,000. Other flowers on the market in those days were daphne, abutilon, callas, sweet alyssum, poinsettia, eupatorium, heliotrope and a few tea roses. The most profitable white cut-flowers, in the opinion of many florists, were *Stevia serrata*, Double White camellia, *Calla æthiopica*, *Lilium candidum*, *Deutzia gracilis*, and Double White Chinese primrose.

It will be noted that roses were not important in the cut-flower trade of this period. It is a fact that very few were grown under glass. A few florists were growing Bon Silene, Lamarque and Safrano roses, occasionally devoting an entire house to them, but more often in houses with other flowers. The rapidly-awakening demand for all kinds of flowers brought good prices for roses and stimulated the florists to give this flower more attention. The time was one of changing ideals and the old formal camellia, show dahlia and Chinese chrysanthemum were passing, while new and less formal flowers were coming into favor. The flower-buying public, however, wanted something larger than the small tea varieties then grown. Every new variety from Europe that had any promise was tried, and from that day to this scarcely a new introduction has escaped a searching test as to its adaptability for culture under glass. The Marechal Niel was grown for the discriminating trade, and it continued the leading variety until it was supplanted by the everblooming, more prolific and more easily cultivated Perle des Jardins. Likewise, the hybrid perpetuals were tried, and some of them, notably General Jacqueminot, were found to force well. This variety, when it could be had for the holidays, brought \$1 and \$2 a bud.

The roses of this time were produced on plants grown in deep beds or in pots or boxes. The latter method enabled the grower better to time his crops, while the former involved less time and attention. The endeavor to secure the advantages of both naturally resulted in

the shallow raised bench, and this method of growing cut-flowers has been adopted for practically all now grown in large quantities; in fact, this system of culture is perhaps the greatest single feature which distinguishes American floricultural methods from those of Europe. Simultaneously it became very generally recognized that to grow roses successfully required separate houses and a different temperature. For a long time it was thought that a special form or construction was necessary, viz., the three-quarter span, but now the even-span house is in general use.

#### *The present cut-flower production.*

Having made these important advances in cultural methods, it needed but the introduction of the epoch-making rose, Catherine Mermet, to place the rose in the first place among cut-flowers. This variety came at once into great popularity with the flower-buying public and was very profitable to the growers, thereby attracting capital to the flower business. The competition to produce and market the best quality of flowers elevated the standards in cut-flowers to a higher level. Although the introduction of Catherine Mermet did much for the flower business, it is as the parent of Bride and Bridesmaid that the variety is generally remembered. These "sports" have been the leading white and pink varieties for twenty years, and have been displaced only during the last five years by White Killarney and Killarney, although many claimants arose to dispute their leadership. These roses succeeded because they were profitable with every florist who could grow roses, and it is doubtful whether we shall ever see varieties so generally successful over so wide a territory. The market is seeking a greater variety among roses than it did during the years these roses held sway, but all this is advantageous to the rose specialists. Next in importance to Bride and Bridesmaid and their successors, White Killarney and Killarney, is the American Beauty (Madame Ferdinand Jamain). This variety can be grown successfully and profitably only by growers who have special conditions. As the variety is still without a rival, it continues to be popular with the wealthy flower-buyers.

The American carnation may be regarded as the greatest contribution America has yet made to the floriculture of the world. The plant is unlike any type grown in Europe and its development is due to American plant-breeders, Dorner, Fisher, Ward and many others. During the last fifty years it has been improved in form, size, color and productiveness. Hundreds of varieties have been introduced and the progress has been so rapid that the best have lasted but a few years. Within the last ten years the American carnation has become popular in England, and now new varieties are appearing from over the sea. The United States census of 1890 shows that roses were first, carnations second, and that the two comprised 65 per cent of all cut-flowers. This relative standing has been maintained to the present time.

The development in chrysanthemums has been no less marked. From the old formal Chinese sorts, the popular fancy turned to the large informal Japanese kinds. Now a change to the single and pompon types is being experienced. The varieties of greatest commercial importance have been for the last ten or fifteen years of American origin. The English, French and, finally, the Australian varieties have led as exhibition flowers, but only an occasional variety has proved meritorious as market cut-flowers. (See *Carnation*, *Chrysanthemum*, *Rose*, and other special articles.)

At the present time the important cut-flowers are roses, carnations, violets, chrysanthemums, sweet peas, lilies, narcissi, orchids, lilies-of-the-valley, mignonette, snapdragons, marguerites and gardenias. A modern cut-flower establishment in the region of New York

grows for its wholesale trade the following numbers of plants:

Roses.....	100,000
Chrysanthemums.....	240,000
Carnations.....	45,000
Lilies.....	(75,000 for Easter) 150,000
Lilies-of-the-valley.....	300,000
Orchids.....	25,000

These are grown in a range of houses comprising 900,000 square feet of glass requiring 8,000 tons of coal, 300 employees, 25 horses, 4 automobiles, and a 250-acre farm with a dairy of 160 cows to supply the manure required.

The past ten years have witnessed the development of the new winter-flowering types of sweet peas, and now these flowers bid fair to rival the violet and chrysanthemum for position after roses and carnations.

Orchids, particularly cattleyas, now are being grown by commercial florists for cut-flowers. Although of recent development, during the last ten or twelve years, all large establishments have an orchid department, while many smaller growers are specializing in their culture.

Lilies, through the means of cold storage, may now be had by forcing throughout the year. The varieties of Japanese longifloras have largely supplanted the old *Lilium Harrisii* kind. *Lilium speciosum* varieties are now largely grown.

The antirrhinum is now being grown by several specialists and doubtless will yield varieties adapted to greenhouse culture.

The most important outdoor flowers for cutting are peonies, gladioli and asters. The peony is now a most important Memorial Day cut-flower, and many acres are devoted to its culture in regions in which the improved varieties mature their flowers early enough. By means of cold storage, flowers of certain varieties may be kept in good condition for as much as four weeks. The florists are enabled to have a supply of this flower for commencements, weddings, and the like, throughout the latter part of May, June and early July.

Gladioli are increasing in popularity as summer cut-flowers because of their keeping qualities under ordinary conditions. Not only are the white varieties useful, but the magnificent colored varieties are being used in large numbers for bouquets on dining-tables in hotels and restaurants.

#### *The selling.*

The marketing of cut-flowers is a business of itself. Many an excellent grower fails because he is not expert in selling his blooms. The cutting of the blooms must be properly done and at the right stage of development. The proper stage in the development when cutting should be done varies with the variety and the season. Roses should be cut as the petals begin to unfold, when the tip of the bud is bursting and the outer petals have reached the proper color. Carnations are picked when fully developed or when three-quarters developed. The latter stage is determined by the pistils having reached an even length with the center petals. Most flowers should be cut early in the morning, and as soon as cut should be placed in clean fresh water, after which they are carried to the cooling-room. The vases in which the flowers are placed should be deep enough to allow plunging the stems two-thirds their length in water. The temperature of the water should be 10° to 15° higher than that of the cooling-room which is 45° to 50°. The temperature is thus gradually lowered to that of the storage-room. The flowers remain in the cooling-room until the picking is done, when they are graded.

Along with the advance in cultural methods and to meet market requirements, flowers have been graded. Although the kinds of flowers grown and the quality

differ but little in the various flower markets, the grades are not yet uniform. However, this ultimately will be brought about through the Florists' Telegraph Delivery Association, an organization which enables a resident of San Francisco, for example, to have an order filled and delivered at an address in Boston, Montreal, Baltimore or elsewhere. The American Rose Society adopted the following grades for tea and hybrid tea roses: 9, 12, 15, 18, 24 inches of stem. Of course the flowers must be good to accord with this standard. American Beauty is graded: Specials, above 38 inches; fancy, 32 to 36 inches; extras, 24 to 32 inches; firsts, 13 to 23 inches; seconds, 8 to 13 inches; thirds all under 8 inches. On the Chicago market this variety is graded into specials, 36-, 30-, 24-, 20-, 18- and 12-inch stems. Carnations on the New York market are usually graded into fancies, extras and firsts. Fancies are all perfect blooms, from  $2\frac{3}{4}$  to  $3\frac{1}{2}$  inches in diameter, with straight stems 16 to 24 inches or more in length. Extras are those blooms which fall short in one or the other of the above requirements. Firsts comprise all merchantable flowers which do not pass as extras or fancies. During the grading, all the leaves from the lower 6 inches are stripped off as well as any side shoots in the axils of the remaining leaves. Chrysanthemums are classed as small, medium, fancy and special. Whatever the grades used in any market, it is important that they be definite, and that the grower use care in grading his own products.

The present methods of the growers in disposing of their flowers to the retail florists are as follows: The large wholesale growers maintain wholesale stores of their own, dealing with the retailers direct and conducting a shipping trade. The growers at a distance from the city market usually consign to the wholesale commission florist whose field is as broad as that of the wholesale grower. These two classes of florists keep in close touch with their customers, even those at a distance, by the ordinary means of communication and in some cases by traveling representatives. The smaller growers living close to a large city adopt any one of five methods, that is, (1) form a coöperative association with an expert salesman to sell the flowers; (2) organize a flower-market and operate a flower-stand; (3) consign the flowers to a commission florist; (4) supply certain retailers regularly; (5) operate their own retail stores. The particular method to be adopted in any individual case depends upon the local conditions and the business ability of the grower. The grower-specialist usually will find it more remunerative to arrange with retailers better able to dispose of his high-class product.

The development of the methods of packing and handling flowers has been a great factor in the business. In the old days flowers were brought to market, or as was more often the case, the retailers went to the growers and carried them into the city in market-baskets. They were delivered to the customers in the same way. When flowers were to be shipped, which was seldom, any convenient box was adapted to the

purpose. At present the florists employ wooden and folding paper boxes for different classes of trade. These are in various sizes adapted to the kind of flower to be packed and to the quality shipped. Furthermore, the package is clean, light, strong and entirely in keeping with the goods. The perfection of the railway and express service has facilitated the delivery of flowers to the consignee. Not only has this enabled growers to get their flowers to the city, but has made it possible for florists over the country to secure flowers when they do not have a sufficient supply. The great wholesale flower business of Chicago is built in a large measure upon the demand of florists in towns and cities over the vast territory extending from Winnipeg to the Gulf of Mexico, and from the Alleghanies to the Rockies.

The packages now used to carry the flowers to the wholesale market are either return or gift boxes; the former, are strong wooden boxes with a hinged lid 12 to 16 inches wide and 5 to 6 feet long. These packages are returned to the grower. Some do not find it profitable or possible to have shipping-boxes or crates returned and must use gift boxes which may be of wood or heavy paper. The common box used by the wholesalers in shipping flowers to distant customers when the package must be handled many times, is the light wooden box. This is made of thin wood,  $\frac{1}{2}$ -inch ends and  $\frac{1}{4}$ -inch tops, bottoms and sides, with two interior cleats to hold the flowers down. These boxes are made in sizes 4 to 8 inches deep, 12 to 16 inches wide, and 36 to 50 inches or more long. The boxes are first lined with paper,

1159. Carnations packed for shipment.

usually four to eight thicknesses of newspapers, according to the season. Then a layer of waxed paper is put in. Roses, whether on their way into or out of the wholesale market, are seldom bunched. Carnations, when shipped out or when sent in by a wholesale grower to his own store, are usually not bunched, but growers who sell through the commission florist should bunch the flowers as it facilitates handling when the flowers arrive on the market. Sweet peas, violets and similar flowers are always bunched. The number of flowers in a bunch will depend upon the requirements of the market. Usually sweet pea bunches contain twenty-five; violets, fifty or one hundred; peonies, thirteen; and carnations, twenty-five flowers. The bunches of violets are encircled by a rim of twenty to thirty leaves and the combination must be attractively done if even the best flowers are to bring a good price. Sweet peas are bunched without foliage, while most flowers bear their natural foliage.

Long-stem flowers, such as roses and carnations, when not tied in bunches, are packed one by one in rows across the width of the box, beginning at one end. The first row rests upon a pillow made of a roll of paper, and each succeeding row is separated from the preceding row by a strip of wax paper. This continues until five rows have been put in each end of the box. Five or six rows of flowers in each end constitute a layer. The flowers of each layer are covered with a sheet of wax paper, and the packing goes on until the box is filled; but only four to six layers should be put in a box.

Over the stems in the center are placed eight to ten thicknesses of well-saturated newspapers, after which cleats are nailed in place. This will prevent the flowers from becoming disarranged in shipping. When different grades of roses are to be packed in the same box, the specials are placed in first unless shipment has a long distance to travel, when two or three rows of the cheap, short grades should go next the end of the box because of danger of injury to the flowers. Each grade is separated from the next by sheets of tissue paper and the different grades are filled in until the short lengths complete the box. It should be a general rule to pack white flowers in the top of the box. Every box should contain a statement of the contents for the information of the recipient. No icing is usually needed in winter, but in warm weather the foliage of roses may be sprinkled with water or chipped ice. Carnations are cooled by lumps of ice wrapped in wet newspapers and placed between the cleats of the boxes. Violets are preserved by wrapping the stems in soft tissue paper and dipping this in cool water. Sweet pea stems are wrapped in wet cotton wool, great care is being taken to prevent wetting the blooms.

In the early days of the cut-flower business, the grower retailed his own flowers. He found time to propagate the plants, tend the furnace, grow the crops, cut the blooms, make floral designs and, if necessary, pack and ship his product. The rapid growth of the cities, making it impossible for the florist to conduct his business near the centers of trade, led to the retail florist. This man, having no glass, could open a flower-stand or store in the most favorable locations, giving it his entire time. The present-day flower stores are the achievements of his skill and industry in developing the art side of the florist business.

#### *The changing demands.*

The uses to which cut-flowers are put have changed. Forty years ago the taste was for formal designs. The flowers were picked with short stems, and in the case of carnations only the open buds were cut, while the remaining buds on the stem were allowed to develop. These flowers were wired to wooden sticks for basket work or to broom-corn straws for bouquets. The details for making the formal pieces of that time will be found in Henderson's "Practical Floriculture." That the florists of that day enjoyed a good trade is seen in the fact that on New Year's Day, 1867, one New York firm sold \$6,000 worth of flowers, and it was estimated that the total sales in the city amounted to \$50,000. The same authority estimates the annual sales of flowers in New York at \$400,000 and in Boston \$200,000. Probably the sales of the whole country did not exceed \$1,000,000. Often \$200 or \$300 were spent for flowers for a reception, and the spending of \$1,500 for a similar purpose, as well as a \$6,000 church decoration, were then the highest achievements of the profession.

The public taste of the present day is for loose, artistic arrangements of long-stemmed flowers. The popular funeral emblems are forms of the wreath which are either made of one kind of flowers or of a great variety of material. Flat sprays and bunches of flowers, and palm (sago) leaves tied with ribbon are also commonly used. House decorations consist of vases of long-stemmed flowers. Roses, carnations, chrysanthemums, peonies and gladioli are suitable for this purpose. Table decorations for dinner are also made of long-stemmed flowers in vases, with some placed on the cloth with ferns or asparagus. Bridal bouquets are arranged often in shower effects by means of narrow ribbon. A remarkable advance has been made in the use of ribbon. Instead of the florist going to the nearest drygoods store for the ribbon he needed, the present-day florist carries his own supply of specially prepared ribbon. As soon as a new shade of color appears in roses, a new ribbon is manufactured to match the

color. The accessories now required to conduct a successful florist business are numerous, requiring a considerable outlay of money; and the trade in this class of floral supplies is a very large one. Every large city now has its supply houses. The kinds of flowers used throughout the United States and Canada vary very little and this is confined to varieties rather than species. The growth of the cut-flower business in Canada also has been rapid, and artificial boundaries have not divided the florists of the two countries. A good book on cut-flower culture is "How to Grow Cut-Flowers," by M. A. Hunt. There are no works on the handling of cut-flowers. On the use and arrangement of flowers, the best literature is found in the current trade papers. Among the foreign works which may prove helpful are "Floral Decoration," by Felton; "The Book of Cut-Flowers," by R. P. Brotherston; and the German special journal, "Die Bindekunst."

A. C. BEAL.

**CUTTINGS, PROPAGATION BY.** A cutting is the gardener's name for a piece of stem, root, rootstock or leaf, which, if cut off and planted under suitable conditions, will form new roots and buds, reproducing the parent plant.

The word cutting, when unrestricted, is given to parts of the stem; a part or the whole of the leaf, when so used, is called a leaf-cutting; a piece of root or rootstock is called a root-cutting. The scales of some bulbous plants, as of the lily, can also be used as cuttings. A cion used in grafting might be called a cutting which unites and grows on another plant. Plants secured by division or layering are provided with roots before they are detached from the parent plants, and, therefore, are not properly cuttings. There are intermediate states between these different categories, however, so that hard-and-fast definitions do not hold.

1160. Section of propagating-bed. Shows four pipes beneath, the door in the side, and the frame cover.

The practice of propagating by means of cuttings, together with the discussion of the reasons, results and bearings, constitutes a department of horticultural knowledge that has been denominated *cuttage*, as the practices, reasons and philosophy of tilling have been called tillage.

Multiplication by cuttings is a form of bud-propagation in contradistinction to sexual reproduction, i.e.,

1161. Permanent propagating-frames in a greenhouse.

propagation by seeds. It is a cheap and convenient way of securing new plants. All plants cannot be profitably increased by these means. Why they differ we do not know; the gardener learns by experience what species yield a good percentage of healthy plants, and acts accordingly.

The following table will show the different ways in which cuttings are made:

Cuttings	Stem. ....	Growing wood.	Soft e.g., verberna.
			Hardened e.g., tea roses.
		Ripened wood.	Long, in open air e.g., grape.
			Short, under glass e.g., Japanese cedar.
	Roots or rootstocks.		Short, under glass e. g., <i>Anemone japonica</i> .
			Long, in open air e. g., blackberry.
	Leaf. ....		Entire e. g., echeveria.
			Divided e. g., <i>Begonia Rex</i> .
			Bulb-scales e. g., lilies.

There is less variation in cutting-progeny than in seed-progeny, and therefore cuttings (or layers or cions) are used when it is desired to keep a stock particularly true to name. They are used largely for the multiplication of forms that are specially variable from seed (which have not become fixed by seed selection), and of mutations as between the different branches or parts of a plant (bud sports). Thus, the varieties of roses, chrysanthemums, carnations, most begonias, and currants and grapes can be grown from cuttings. Cuttings are also employed when seeds are difficult to secure, as in many greenhouse plants, or when propagation by seeds is difficult and cuttings are easy, as in poplars and willows.

#### The cutting-bed.

Under glass cuttings are commonly planted in pure sand, such as a mason would use for making mortar. Sphagnum moss is sometimes used and various substances like brick-dust, coal-ashes jadoo fiber have been tried, but without much success. Sand and well-rotted leaf-mold mixed half and half, is occasionally employed for geraniums, for lily scales, root-cuttings and some succulent plants.

Sphagnum is useful in rooting *Ficus elastica*, the base of the cutting being wrapped in a ball of moss and plunged in a bed of moss. English

ivy, oleander and other plants can be struck in water, but this method is cumbersome. Peter Henderson's saucer method is valuable in hot weather: the cuttings are planted in sand, kept saturated and fully exposed to sun.

In the open air, a well-protected place, a part of the frame-yard, for example, should be chosen for a cutting-bed. The aspect should be southerly and the soil must be well drained. The soil should also be trenched to the depth of 2½ to 3 feet, all poor material removed and additions of humus, in the form of peat, leaf-mold or well-rotted barnyard manure incorporated. Provision for watering should be easy. If the soil is a heavy clay, add sand.

Structures in which cuttings are started.  
Figs. 1160-1165.

Large establishments have one or more houses set apart for this and similar purposes called "propagating-houses." In smaller places a propagating-bed or -bench can be made at the warmest end of the warmest house. It should be placed over the pipes where they leave the boiler, and, in order to secure bottom heat when needed, the space between the bench and the floor should be boarded up, having a trap-door to open on cold nights (Fig. 1160). Cutting-frames inside a greenhouse are also shown in Fig. 1161. Side partitions should also be provided to box in all the heat from the pipes under that part of the bench. Good dimensions for such a bed are, width 3 feet, length 6 feet or any multiple of six thus making it simple to use a hotbed sash when confined air is wanted. The depth of the frame should be from 6 to 10 inches in front and about the same behind. The bottom of the bed may be either wood, slate or metal and should be well drained: place a layer of potsherds first, then moss, and from 2 to 3 inches of sand on top. The sand should be clean, sharp and well compacted: before planting it should be watered if at all dry. It is sometimes advisable to have the bed filled with moss (sphagnum), into which pots or boxes containing cuttings are plunged: the moss should be moist, neither too wet nor dry, and well packed.

In many cases, when large quantities of one sort of easily struck cuttings are to be planted, the ordinary greenhouse bench covered with sand is sufficient (Fig. 1162).

Hand-lights and bell-glasses are sometimes used under glass for small quantities of cuttings instead of frames. They may be of every convenient size up to 12 or 15 inches in diameter. The important point is that

1162. Cutting-bench shaded with lath.

provision for good ventilation be always provided: if too much water accumulates inside the glass it can be wiped off with a cloth. They are somewhat obsolete devices for providing a close atmosphere and intensifying bottom heat. The modern gardener finds that sunlight and shading with awnings put directly over the cuttings is quite sufficient for all plants except a few

1163. Propagating-box.

difficult subjects. Figs. 1163-1165 illustrate forms of hand structures. Out-of-doors cold-frames are employed for striking cuttings in summer. They are made of concrete or plank, and are about 5½ feet wide, 18 inches deep behind and 12 inches in front. They are of any convenient length, which is a multiple of three and are covered with standard hotbed sash. Instead of coldframes, light hotbeds are sometimes employed for rooting cuttings in the open air in summer. They entail more care and the results do not offset the gain.

*Cuttings of growing wood.* Figs. 1166-1171.

These cuttings are made either of the soft growing tip, as in coleus (Fig. 1166; also Fig. 1027, p. 827), salvia, verbenas (Fig. 1167), geranium (Fig. 1168) and others, or, of the same wood in more mature condition, but by no means ripe, as in tender roses (Fig. 1169), and *Azalea indica*. The cuttings of plants like *Euphorbia pulcherrima*, erica, epacris, are used in the soft growing state, if a well-built propagating-house is obtainable; but in an ordinary house, a part of which is used for other purposes, the older and better ripened wood will be more successful.

It is generally true that cuttings of hardened wood will always root, although they require more time and may not make the best plants, but it is not true that cuttings of the soft wood will always root. In many cases, as in the rose, they succumb before they callus, much less produce roots. In plants of rapid growth and good vitality, the proper condition of the soft growing wood for cuttings can be determined by its readiness to snap, not bend, when bent back: the hardened wood is in the right state as long as it continues to grow.

The treatment of cuttings in both classes is practically the same. They should be planted in sand under glass.

The wood for soft cuttings should be fresh, and precautions should be taken to prevent wilting during making and planting: if the weather is hot, sprinkle the floor and bench of the workroom: if they are delicate and exposed for an hour or more, lay them between folds of moistened paper. The average length of these cuttings is from 1 to 3 inches, but they can be made longer or shorter; much depends upon the nature of the plant. The best growers prefer short cuttings; the advantage of a long piece to begin with is more than offset by greater danger of wilting and consequent retrogression. It is not necessary to cut to a bud, i. e., at the node, in the more easily

handled plants except in some herbaceous tuberous-rooted plants, like dahlia (see Fig. 1170), and *Salvia patens*, in which a crown must be formed to insure future growth. Make the cut where it will give the proper length. A part of the leaves should be removed, always enough to secure a clean stem for planting, and as many more as are needed to prevent disastrous wilting: this factor varies greatly. In a hardwood cutting of lemon verbenas all leaves are taken off, in zonale geraniums from the open ground few if any are left, in coleus and verbenas about one half are removed, while in *Olea fragrans*, *Daphne odora*, and heath, only enough for planting. Use a sharp knife; but scissors are handy for trimming and sometimes for making cuttings of those small-wooded plants which root easily.

The cuttings of plants with milky juice should be washed before planting. Sometimes the lower ends are allowed to dry for several hours, the tops being protected against wilting. Large and succulent cuttings, e. g., of pineapple, cotyledon and cactus, should be dried before planting by letting them lie on the surface of the propagating-bed for several days, or they may be planted in dry sand at first. Under these conditions a callus forms which tends to prevent decay; but the wood must not shrivel.

Peter Henderson has introduced a method which is likely to increase the percentage of rooted plants, and which is desirable in slow-growing varieties, like the tricolor geraniums. He advises that the cutting should be partly severed and allowed to hang to the parent plant for a few days; this results in a partial callus or even roots, before the cutting is entirely removed.

In planting cuttings, use a dibble or open a V-shaped trench. Never thrust the cutting directly into the soil. Plant deep enough to hold the cutting upright and no deeper (as in Fig. 1171), making due allowance for the sand settling; the distance apart should be just enough to prevent them from pressing against each other. It must be remembered that they stay in the bed only until rooted. As soon as growth begins, they are potted off. When the cuttings are inserted, the sand should be firmly pressed about them, and they should be watered with a syringe or with a fine rose; the forcible application of water compacts the sand, thus excluding air, and prevents undue wilting.

Give shade immediately, using lath shutters outside, cloth screens or papers placed directly on the cuttings within, and attend to this very carefully for the first few days. Lift the shades early in the afternoon, and put them on late in the morning, but keep them on during the middle of the day, thus gradually accustoming them to full light.

Cuttings should never suffer from dryness. The sand should always be kept moist to the verge of wetness. Ventilation should be given on bright days, but all exposure to draft avoided. A good temperature for propagating is from 60° to 65° F., increasing these figures for tropical plants and reducing them for more hardy kinds. It is debatable whether bottom heat and

1166. Cutting of soft growing wood. (as of Coleus.)

1164. Propagating-box or hood.

1167. A rooted verbenas cutting.

1165. Small propagating-box, adapted to a window.

confined air are advisable for cuttings of growing wood. The older gardeners employed both, but now neither is commonly used, except for tropical plants, like croton, or when a constant succession of crops of cuttings is required. There is no doubt that with this aid cuttings will root more quickly, but more skill and care are required, neglect bringing on fungous disease, which results in unhealthy plants or total loss. If bottom

1168. A geranium cutting.

1169. A rose cutting.

heat is used, the average temperature of the bed should be 10° or so above that of the air, but less will suffice. Indeed, in beds made as described above, in good weather the sand is enough warmer than the greenhouse atmosphere to answer every purpose. If a confined air is wanted, ventilation and shading must be carefully looked after, and precautions taken against the accumulation of condensed moisture within the bell-glass or frame.

Although it is tender plants, in the main, that are propagated by cuttings of growing wood, the above methods can be practised advantageously with some hardy plants. The wood, which is invariably more successful if hardened, is obtained either from plants forced for this purpose, e. g., *spirea*, *Deutzia gracilis*, or it is gathered in June and July out-of-doors, e. g., lilac, hydrangea. They should be potted off in 2- or 3-inch pots, in a rather sandy soil, when the roots are from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch long. It is sometimes good economy to box them, i. e., plant them a few inches apart in flats, when not immediately required.

Some hardy perennials, like *Phlox subulata*, *Campanula carpatica*, *Gentiana acaulis* and the hardy candytuft, can also be easily increased in this way. Make the cuttings 2 to 3 inches long and plant in flats or pots in sand or a sandy soil in October, November or December, before any hard frost. Keep in a coolhouse and pot off when rooted. They make nice plants for planting out the following spring. Plants of this same nature can also be propagated in the open air in autumn. Make the cutting longer, 6 inches when possible, and do the work earlier, in September or in August in some cases.

1170. Hardened-wood cutting of dahlia.

1171. A carnation cutting.

1172. Hardwood cutting of currant.

*Cutting of ripened or dormant wood.* Figs. 1172-1174.

Many plants grow readily from twigs of the year's growth taken in fall or winter or very early spring. The "soft-wooded" plants usually propagate most readily by this means. These cuttings of mature wood may be either long or short.

*Long cuttings of ripened wood in open air.*—This method is used to propagate many hardy trees and shrubs, e. g., willows, currants, grapes, forsythia. Wood of the current year's growth is gathered in autumn or early winter, before severe frost, and either stored in a wool cellar, covering with moss or fresh earth to prevent drying, or immediately made into cuttings. These cuttings are usually 6 inches or more long and should contain at least two buds. It is not necessary to cut to a bud at the base, but the upper cut should be just above one. Figs. 1172, 1173. They should be tied in bundles with tarred rope, taking care to have them lie "heads and tails" to facilitate planting, and with the butts on the same level, to promote callusing. They should then be buried in well-drained soil, with the butts down and protected against frost. In early spring they should be firmly planted in V-shaped trenches in well prepared soil: set an inch or so apart, with the rows 1 or 1½ ft. apart. The upper bud should be just at the surface; to prevent suckers the lower buds may be removed. In autumn they should be dug, graded and heeled-in for winter. Some varieties will require a second or third year's growth in the nursery; others are ready for permanent planting, as willows and poplars, which often grow 6 feet the first year. This is one of the very cheapest ways of propagating, and will pay when only 25 per cent root. This method is generally used with deciduous-leaved plants, but some conifers, e. g., Siberian arbutus, will strike. Remove enough twigs to get a clean stem for planting, and allow 2 or 3 inches of top above ground.

1173. Cuttings of grape, to show how planted.

The excrescences, knots or knaurs, which are found on the trunks and the main limbs of olive trees, are sometimes used as cuttings for propagation.

*Short cuttings of ripened wood.* (Fig. 1174.) Cuttings of this class are used under glass with tender or half-hardy species, and sometimes with new introductions, in cases in which the grower is short of stock, and when the plant is delicate and small. The wood should be gathered before severe frost and the cuttings made and planted directly in October and November. Make them from 2 to 4 inches long (sometimes a single eye only is used), and plant with a dibble, in pure sand in pots, pans or flats (boxes about 16 inches square and 3 inches deep). If a layer of potting soil is placed under the sand, the young plants have something to feed on and do not need to be potted so soon after rooting; if this is done, drainage should be given. It is important to keep them cool until a callus is formed or roots produced. If the buds start into growth before this, the cuttings become exhausted and are likely to die. After rooting,—the time required varies from one to six months—they may either be potted or the strong-growing sorts be planted out in well-prepared beds in May or June, where they are likely to make a satisfactory growth. The weaker kinds may remain a year in pots or flats, be wintered in a pit, and planted out the next spring. Some greenhouse plants, e. g., camellia, laurustinus, tender grapes,

are propagated in this way with cuttings of fully ripened wood, and others, as cactus and dracena, with wood which is much older. They should be given the care described under the head of "Cuttings of growing wood" (p. 927), but they must not be forced too hard at first. The temperature should be regulated by the nature of the plant. The safest rule to follow is to give a few degrees more heat for propagating than the plant received when the cutting was removed.

Hardy shrubs can also be propagated by cuttings of growing wood, somewhat hardened, planted in coldframes in June and July. They are called "cuttings of green wood," and are made from 4 to 6 inches long and sometimes longer. They are closely planted in sand, or soil one-half sand and one-half leaf-mold, in rows 4 to 6 inches apart. They must be carefully watered, shaded and ventilated for ten days or more after planting. Much of the success of this method depends upon the weather; it brings in a gambling element: a few hot and dry days are dangerous. A light hotbed may be used instead of a coldframe but this means more care. The rooted plants are left in the frame all winter, protected and planted out the following spring.

#### Root-cuttings. Fig. 1175.

The cuttings of this class are made of either root or rootstock and are useful in propagating some plants, either in the greenhouse or in the open air. Tender plants, like bouvardia, and those which are hardy but of delicate growth, e.g., *Anemone japonica*, are handled under glass; blackberries, horse-radish, and so on out-of-doors. The cuttings are made in autumn or winter, the roots of hardy plants being gathered before severe frost and either planted directly or kept in moss until spring. This process of storing develops a callus and has a tendency to produce buds. For greenhouse work, the cuttings are made from 1 to 2 inches long, the larger roots being selected, although the small ones will grow. They are planted in pans or flats, in soil composed of equal parts sand and well-rotted leaf-mold. Ordinarily they are set horizontally. If planted vertically, in cuttings from the true root, the end which was nearest the crown should be uppermost; but if made from the rootstock, that end should be uppermost which grew farthest from the crown. In either case they should be covered, as seeds are covered, and the whole made firm. Root-cuttings of hardy plants should be kept cool at first and brought into heat only when ready to grow. They may be kept in a pit or cool cellar. Tender plants require the same or a little higher temperature than that in which they thrive.

In sweet potato, the tuber is cut lengthwise and laid, with the cut side down, on moist sand or moss, the edges being slightly covered. Buds develop on these edges and are removed when of proper size and treated as cuttings of growing wood, or allowed to remain until rooted. In dracena (see Fig. 1052, page 842)—and this applies to stem- as well as root-cuttings—the buds are not taken off until rooted the original cutting remains

1175. Root-cutting of blackberry.  
( $\times \frac{1}{2}$ )

in the sand and sometimes produces a second or even a third crop. The tuberous rootstock of *Arum maculatum*, and plants of like nature, can be cut into pieces, remembering that the bud-producing portion of arum is the top, and each part will grow successfully. Exercise care in watering and maintain a good temperature.

1174. Short cuttings of ripened wood.

The rootstocks of cannas are cleaned and cut into pieces  $1\frac{1}{2}$  to 2 inches long and planted in a warmhouse in February (Fig. 784, p. 657). As soon as buds push and roots form they are potted off and grown until the season for bedding out. Dahlias are not, properly speaking, propagated from rootstock, but by division; the plant cannot produce adventitious buds. There must always be a bit of the crown attached to the tuber. The propagation of dahlias so closely resembles the methods here described that it is perhaps well to mention it.

Root-cuttings for planting in the open ground are made from 4 to 6 inches long, and are planted firmly in V-shaped trenches or furrows in spring, being covered 2 inches or more deep. Roots as large as one's little finger are chosen, and good results are secured with plants of vigorous growth. In plants like lily-of-the-valley, common lilac, calycanthus, Scotch and moss roses, unless short of stock, it is better to encourage the natural growth of the suckers and propagate by division, but they all can be multiplied as above described.

Variation, curiously enough, is not always reproduced by means of root-cuttings.

#### Leaf-cuttings. Fig. 1176.

Many leaves are capable of producing roots. Some have the further power of developing buds after rooting, and of these last a few furnish an economical means of bud-propagation, particularly when the stem growth is insufficient. In cotyledon (echeveria) the whole leaf is used, the smaller ones from the flower-stalk being often the best. Choose those that are fully matured, and dry them for a few days on sand, but do not let them shrivel. The treatment, otherwise, is as given above for cuttings of growing wood. In gloxinia and other Gesneraceæ, the whole leaf (Fig. 1176), half a leaf, or even a lesser portion, is used. When enough clear petiole is obtainable, no further preparation is needed. When a part only of the leaf is planted, some of the blade must be cut away. As a rule, no bud is developed the first season: a tuber is formed, which will grow in due time.

1176. Leaf-cutting of gloxinia.

1177. Lily scale producing bulblets.

The common *Begonia Rex* is increased by leaves in various ways. The whole leaf may be planted as a cutting, keeping the petiole entire or cutting it off where it unites with the blade; or the whole leaf may be pinned or weighted to the surface of moist sand (Figs. 501-503, p. 470), and, if the principal veins are severed at intervals of an inch, a plantlet will appear at every cut. The best way is to divide the leaf into somewhat triangular pieces, each part having a strong vein near the center. Plant in sand, in good temperature, and treat precisely as if they were cuttings of growing wood. Roots and buds will soon grow, and a good plant will result within a reasonable time. Pot off when roots are  $\frac{1}{4}$  inch long. Certain other begonias may be similarly multiplied.

#### Other cuttings.

The thickened scales of bulbs, like lilies, can be used for propagation. Remove the scales intact and plant upright, like seeds, in soil made of equal parts of sand and rotted leaf-mold (Fig. 1177). September and October are the usual months for this work. If they

are kept in a cool greenhouse, the young bulblets will appear in the course of the winter, but top growth will come later, in summer. This is a slow, laborious process, and is seldom practised except in propagating new varieties. The granular scales of achimenes and plants of like nature can be used for propagating, sowing them in a sandy soil as seeds are sown; but this method is not a good one in ordinary cases. The scales of *Zamia horrida* have been made to produce new plants, as have also the tunicated scales of an amaryllis.

For further details of cuttage, consult Lindley's "Theory and Practice of Horticulture," 2d ed.; Burbidge, "The Propagation and Improvement of Cultivated Plants;" Peter Henderson's "Practical Floriculture;" Bailey's "Nursery-Book."

B. M. WATSON.

**CYANÁNTHUS** (Greek for blue flower). *Campanulaceæ*. Ten or a dozen herbs, probably mostly perennial, of the high mts. of Cent. and E. Asia, with showy blue fls. terminating the ascending mostly simple hairy sts.: corolla funnelform, tubular or bell-shaped, 5-lobed; stamens free from the corolla, the ovate anthers more or less connate around the pistil; fr. a caps. with persistent calyx, loculicidally 3-5-valved; lvs. alternate, usually small, entire or somewhat lobed. *C. lobatus*, Wall., may be expected in collections of choice alpine: 4-5 in.: lvs. small, narrowing to base, tooth-lobed at summit; fls. bright blue, 1 in. diam., resembling a shining periwinkle fl., funnelform with reflexed lobes, the corolla exceeding the calyx-tube and hairy in the throat. B.M. 6485. Other species mentioned in recent horticultural literature are *C. microphyllus*, Edgew. (*C. linifolius*, Wall.), with slender wiry sts., small entire lvs., and fls. like those of *C. lobatus* but with very hairy throat and longer narrower segms.; *C. incanus*, Hook. f. & Thoms., with numerous wiry sts., small nearly sessile lvs., and yellow campanulate fls. with hairy calyx; the W. China form of this (var. *leiocalyx*) has a less hairy calyx; *C. Hookeri*, Clarke, is an annual with small stalked lvs. and blue fls., from China and India; has rigid sts. with short lateral fl.-branches. L. H. B.

**CYANÉLIA** (from the blue color). *Amaryllidaceæ*; it has been referred to *Liliaceæ* and also to *Hemodoraceæ*. A half-dozen or less small bulbs from S. Afr., sometimes grown in the way of ixiads. Plants with rhizomes or tunicate corms, radical or basal lanceolate or linear lvs., and simple or rarely branched sts.: fls. violet, rose, yellow or white, solitary or racemed-paniculate; perianth-tube 0, the segms. distinct or very nearly so; stamens 6, attached to base of segms., all perfect, often dimorphous; fr. a loculicidal 3-angled caps., on bractless pedicel. The cyanellas are summer- and fall-flowering bulbs with us. The following are the kinds likely to be found: *C. capensis*, Linn. Lvs. lanceolate, undulate: st. paniced, leafy, 1 ft.: fl. purple. B.M. 568. *C. lutea*, Linn. f. (*C. odoratissima*, Lindl.). Less branched; lvs. linear-lanceolate, acuminate, not undulate: fls. rose, changing to yellow. B.R. 1111.

L. H. B.

**CYANIDING, CYANIDIZING:** *Diseases and Insects*, p. 1044, discussion of fumigating by hydrocyanic acid gas.

**CYANOPHYLLUM:** *Tamonea*.

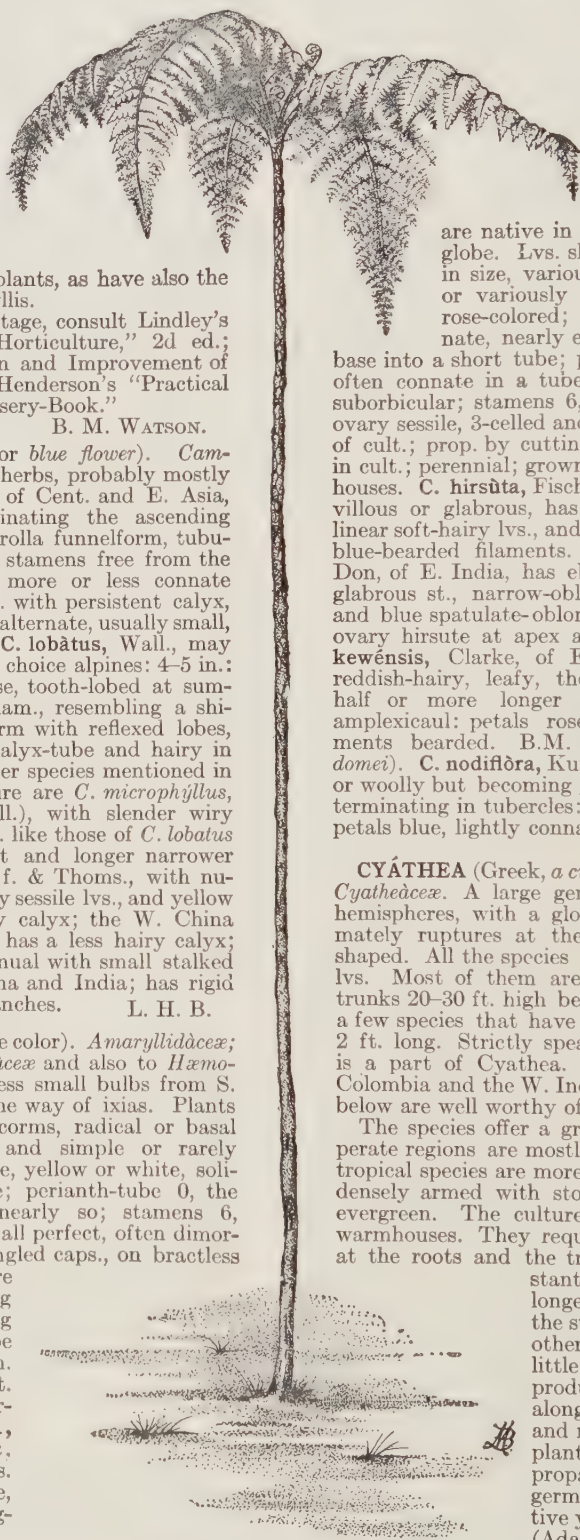

**CYANÔTIS** (Greek, referring to the blue petals). *Commelinaceæ*. Probably 40 creeping, ascending or weak branching often woolly or hairy herbs, much like Tradescantia; they

are native in warm countries about the globe. Lvs. sheathing, small or medium in size, various: fls. in scirpioid cymes or variously disposed, mostly blue or rose-colored; sepals 3, lanceolate-ciliate, nearly equal, usually combined at

base into a short tube; petals 3, also nearly equal, often connate in a tube, the limb spreading and suborbicular; stamens 6, all perfect, nearly equal; ovary sessile, 3-celled and each cell 2-ovuled. Easy of cult.; prop. by cuttings. There are few species in cult.; perennial; grown in greenhouses or warm-houses. *C. hirsuta*, Fisch. & Mey., from Abyssinia, villous or glabrous, has erect st., globose tubers, linear soft-hairy lvs., and rose-colored perianth and blue-bearded filaments. B.M. 7785. *C. barbata*, Don, of E. India, has elongated branching nearly glabrous st., narrow-oblong or nearly linear lvs., and blue spatulate-oblong petals free to the base: ovary hirsute at apex and the style bearded. *C. kewensis*, Clarke, of E. Indies, is procumbent, reddish-hairy, leafy, the branches fleshy: lvs. a half or more longer than broad, sessile and amplexicaul: petals rose-purple, ovate, free; filaments bearded. B.M. 6150 (as *Erythrotis Beddomei*). *C. nodiflora*, Kunth, of S. Afr., is cobwebby or woolly but becoming glabrous, the fibrous roots terminating in tubercles: lvs. narrowly lance-linear: petals blue, lightly connate. B.M. 5471. L. H. B.

**CYÁTHEA** (Greek, *a cup*, alluding to the indusia). *Cyatheaceæ*. A large genus of tree ferns in both hemispheres, with a globose indusium which ultimately ruptures at the apex and becomes cup-shaped. All the species in cult. have decompound lvs. Most of them are large plants, species with trunks 20-30 ft. high being common, but there are a few species that have lvs. and sts. no more than 2 ft. long. Strictly speaking, the genus *Alsophila* is a part of *Cyathea*. Many other species from Colombia and the W. Indies besides those described below are well worthy of cult.

The species offer a great variety. Those of temperate regions are mostly stout and not spiny; the tropical species are more slender and in many cases densely armed with stout spines. All species are evergreen. The culture of cyatheas is simple in warmhouses. They require an abundance of water at the roots and the trunks should be kept constantly moist. The foliage lasts longer if it has been inured to the sun during summer. Like all other tree ferns, cyatheas need little pot-room. They rarely produce adventitious growths along the trunk or at the base and none is proliferous. The plants are, therefore, usually propagated by spores, which germinate freely, making attractive young plants in two seasons. (Adapted from Schneider, "Book of Choice Ferns.")

1178. *Cyathea meridensis*.

XXXIII. *Cycas circinalis*, the male plant.

*A. Rachides unarmed: lvs. white beneath.*

**dealbata**, Swartz. Rachides with pale rusty wool when young; lvs. firm, bi-tripinnate, almost pure white beneath. New Zeal.—*C. Smithii*, Hort., is regarded by some as a horticultural variety.

*AA. Rachides unarmed: lvs. green beneath.*

**Búrkei**, Hook. Stalks with tubercles near the base bearing large, glossy rusty scales: lvs. bipinnate, with broad pinnules. S. Afr.

1179. Fruiting pinnule of *Cyathea meridensis*.

**meridensis**, Karst. Figs. 1178, 1179. Lvs. tripinnatifid, with oblong-lanceolate pinnæ and rather narrow lanceolate pinnules; segms. scaly on the ribs beneath. Colombia.

*AAA. Rachides spiny: lvs. green beneath.*

**medullaris**, Swartz. Lvs. bi-tripinnate, densely scaly when young, with soft, deciduous hair-like scales; segms. coarsely serrate or pinnatifid, on spore-bearing lvs. New Zeal.

*C. angolensis*, Welw. A greenhouse species said to have fronds 6-8 ft. long produced from a trunk which attains 12-15 ft. Trop. W. Afr.

L. M. UNDERWOOD.

**CYCAS** (Greek *kúkas*, the name of a palm tree). *Cycadaceæ*. Several beautiful palm-like plants, common in cultivation under glass. Plate XXXIII.

The *Cycadaceæ* are of great interest because they occupy a place intermediate between flowering plants and the cryptogams. Like the former they have fr. with a large starchy endocarp; but like the latter their sexual prop. is accomplished by means of spermatozoids and archegonia, corresponding to the male and female elements in animals. The plants are dioecious; the male infl. is in the form of an erect cone composed of modified staminal lvs. which bear on the under surface globose pollen sacs corresponding to microsporangia; the female infl. consists of a tuft of spreading carpellary lvs. having their margins coarsely notched; in the notches are situated the ovules, which are devoid of any protective covering, and correspond to macrosporangia. Pollination under natural conditions is effected by the wind. The pollen settles on the ovules and sends down a tube into the tissue of the nucellus. Archegonia are formed; egg-cells develop, and in the pollen-tube are produced spermatozoids provided with minute movable cilia by which they are propelled, very much as in the spermatozoa of animals. These are discharged over the archegonia and fecundate the egg. The discovery of spermatozoids in the cycads was made by a Japanese student, S. Ikeno, while investigating the process of reproduction of *Cycas circinalis*. Those of *Zamia*, endemic in Fla., were described and figured by H. J. Webber, who found the mature spermatozoids of the latter genus to be the largest known to occur in any plant or animal.

Most of the species of *Cycas* are arborescent, having a trunk marked with rings of growth and with the scars of fallen petioles. The trunk is usually simple and columnar (though sometimes it is branched), and is elongated by a terminal bud. The pinnate leaves form a beautiful terminal crown like that of a palm or tree-fern. Cycads are found among the fossils of many geological formations, especially in those of the early Mesozoic. The latter formations are grouped together on this account, and the geological epoch which they represent is sometimes designated as the "Age of the Cycads."

Cycads are among the most ornamental plants of tropical and subtropical gardens. In the United States they are often designated "sago palms," although they have nothing in common with a palm except the general habit of growth. In Florida, according to H. Nehrling who has a plantation at Gotha, near the center of the

state, they thrive equally well on high pine land and in the rich soil of the low hummocks. *C. circinalis* is apparently the most sturdy of the cultivated species. It is almost free from diseases; but it is more sensitive to cold than *C. revoluta*. The latter, on the other hand, is subject to diseases in low flat wooded situations. A third species, *C. siamensis*, which is comparatively rare, seems to be perfectly hardy in Florida. In cultivating cycads, Nehrling has attained the best results by keeping the weeds away from the base of the trees and loosening the soil from time to time, taking care not to injure the small network of tubercle-bearing roots surrounding the trunk. The tubercles, which are about the size of a pea, are interesting to the plant physiologist, and are apparently conducive to the plant's well-being. Nehrling gathers the pollen from the male plants and sprinkles it by hand over the female flowers to insure fertilization of the naked ovules.

Plants are propagated by seeds, which keep well for a month or more after ripening. According to E. N. Reasoner, they should be sown in shallow boxes or the greenhouse bench, lightly covered with sand, and after germination, potted off in small pots of moderately rich, light soil. The growing plants do best in partial shade. The old plants frequently send up suckers around the base of the trunk. These may be taken off when in a dormant state and rooted, care being taken to remove the leaves to guard against excessive transpiration. Growing cycads require sunshine and moisture.

The beautiful glossy leaves of cycads are used in many countries for ornamenting temples and for decorating altars. On the island of Guam they are used for palm leaves on Palm Sunday, and in the early days they were carried by children in religious processions, marching from one village to another under the guidance of the Jesuit missionaries. Cycads are popular conservatory plants, of easy culture, and tenacious of life, even when neglected for a long time. Their stems

1180. *Cycas pectinata*.

deprived of leaves are easily transported in bulk and will soon resume growth when planted. In the southern United States, cycads are injured by frost but often revive after having apparently been killed.

*A. Margins of pinnæ flat.*

*B. Modified fr.-bearing lvs. (carpophylls) spinous-toothed along the margin.*

*c. Scales of male infl. tapering into a long spine.*

*D. Lvs. 5-8 feet long, with pinnæ 10-12 in. long.*

**circinalis**, Linn. (*C. Thouarsii*, R. Br.). **FERN PALM**. A palm-like tree with cylindrical trunk and a crown of

glossy, fern-like, stiff but gracefully curved pinnate lvs.: trunk clothed with the compacted woody bases of petioles, usually columnar and simple, but often branching when the terminal bud has been cut off, or in clusters of several springing from the base of an old trunk which has been cut down; in addition to the true lvs., modified lvs. in the form of simple short subulate woolly prophylla; true lvs. 5-8 ft. long, long-petioled, the petiole bearing short deflexed spines near the base; pinnæ alternate, 10-12 in. long and quite narrow, linear-lanceolate, acuminate, subfalcate, the midrib stout and prominent beneath, bright green above, paler beneath; male infl. in the form of an erect woolly cone composed of scales bearing globose pollensacs on the under surface and tapering at the apex into a long spine; female infl. in the center of the crown of lvs., consisting of a tuft of spreading buff-colored, woolly, pinnately-notched lvs. (carpophylls) about 6-12 in. long, spinous toothed along the margin, and bearing in the notches the naked ovules; ovules 3-5 pairs, borne above the middle; fr. about the size of a walnut, with a thin fleshy covering, and a fleshy starchy endosperm resembling that of a horse-chestnut. S. India, Ceylon, Sumatra, Java, Philippines, Madagascar, E. Trop. Afr., Guam.—In Fla. the lvs. of this species are often destroyed by sharp frosts, but the trunk is rarely injured and will soon send forth new lvs. when the weather becomes warm again. Nehrling recommends that fine specimens be protected by a tent or by a house of lattice-work covered with canvas, and with the sides also inclosed if necessary. In this house a large kerosene lamp will be sufficient to keep the plant from freezing. In Tampa, Fla., this species appears to flourish, some of the specimens having trunks 6-8 ft. high. It grows best in rich moist soil and in partial shade. On the island of Guam, the nuts of this species form a food staple for the natives in times of famine following hurricanes. These are so poisonous that the water in which the kernels are soaked is fatal to animals. After having been soaked for some time and the water repeatedly changed, the kernels become harmless, and are ground up into meal and dried for future use. They are usually prepared in the form of cakes, which are said to be nutritious although rather tasteless.

DD. Lvs. less than 5 ft. long; pinnæ 3-8 in. long.

mèdia, R. Br. NUT PALM of Australia. Trunk attaining height of 8-10 ft. or sometimes twice this

1181. *Cycas revoluta*.

height, rarely branched at the top: lvs. 2-4 ft. long or more, the pinnæ very numerous, straight or falcate, obtuse or pungent-pointed, flat or slightly concave above when young, prominently keeled beneath, the margins often slightly decurrent on the rachis, glabrous or slightly pubescent when young, the longer ones varying from 3-8 in., the lower ones shorter and more contracted at the base, the lowest ones prickly-like, sometimes continuing to base of petiole: cones variable in size, but apparently smaller than in *C. circinalis*, which this species otherwise resembles; seeds 1-1½ in. long, glabrous. Austral, along the northern coasts; also Queensland.

cc. Scales of male infl. shortly acuminate.

Rúmpíi, Miq. Closely related to the preceding, but growing taller in its natural habitat, sometimes reaching a height of 20 ft. or more: lvs. shorter and with fewer lfts.: scales of male cone thickened and obliquely truncate at the tip, with a short upcurved sometimes caducous point; carpophylls a foot long, narrower than in *C. circinalis*, with an entire often elongate subulate tip; seeds oval or subglobose, 2-2¾ in. long by 1½-1¾ in. diam. Moist wooded regions of Burma, Ceylon (possibly intro.), Andaman Isls., Nicobar, Malaya, New Guinea, and N. Austral.—This species when growing in cult. is usually much lower, and has a full large crown of lvs., with lanceolate pinnæ thinner and paler than those of *C. circinalis*. Much grown in tropical gardens of E. Indies; male plants rare.

BB. Modified fr.-bearing lvs. pectinate along the margins.

c. Trunk much swollen at the base: blade of carpophyll ovate-rhomboid.

siaménsis, Miq. A small palm-like tree: sts. 2-6 ft., much swollen at the base: lvs. 2-4 ft., stiff spreading; pinnæ 3-8 in. long, linear mucronate-acuminate; blade of carpophyll tawny-woolly when young, at length glabrescent above, ovate-rhomboid, long-acuminate, margin deeply pectinate lacerate: scales of male infl. about ¾ in. long, with a slender terminal point of the same length: seeds 1½ in. long, obovoid-oblong. Burma, Siam, Cochín China.—Apparently hardy in Fla. It is rare, occurring in only a few gardens. It is a beautiful species, easily recognizable by its trunk which is swollen very much like that of *Dasyllirion*, and according to Nehrling grows much faster than the species more commonly cult. It is certainly deserving of more general cult.

cc. Trunk not swollen at the base: blade of carpophyll broadly orbicular.

pectinàta, Griff. Fig. 1180. A glabrous evergreen palm-like tree, to 10 ft. high in its native habitat but usually much shorter in cult.: lvs. ascending, recurved, 5-7 ft. long; pinnæ 7-10 in. long, narrowly linear tapering into a minute apical spine, subfalcate; blade of carpophyll covered with dense tawny wool throughout, 6 in. long, broadly orbicular, long-acuminate, its margin deeply subulate-pectinate, stalk about equal in length to the blade with 2 or 3 pairs of ovules above the middle; spiny marginal teeth ¾ in. long; terminal point 1½ in. long, tapering from a flat base, with 1 or 2 spinous teeth: seeds about 1½ in. long, ovoid: male cone 18 in. long, 6 in. diam., cylindric-ovoid; anther-bearing scales 1½ in. long, 1 in. diam., deltoide-clavate, the apex much thickened, abruptly acuminate, terminal point 1½ in. long, spine-like, ascending. India, Nepaul, East Bengal, 2,000 ft. elevation, Assam, Martaban, in pine forests. G.F. 4:114 (adapted in Fig. 1180).

AA. Margins of pinnæ revolute.

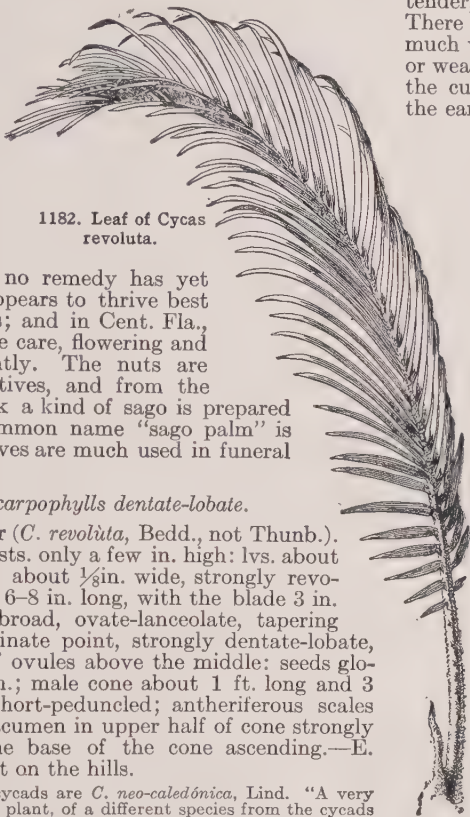

B. Blade of carpophyll pectinate.

revolùta, Thunb. SAGO PALM. Figs. 1181, 1182. A graceful palm-like tree or shrub, becoming 6-10 ft. high, with the trunk simple or branching: lvs. long and recurved (2-7 ft.); pinnæ numerous, subopposite, curved downward, narrow, stiff, acute, terminating in a spine-like tip, dark shining green, the margin revolute; carpophylls with the blade broadly ovate, densely clothed with brownish felt-like wool, pectinate; ovules 2 or 3 pairs borne near the base: fr. ovate, compressed, red, about 1½ in. long. S. Japan.—This is the most common cycas in conservatories. It is of Javanese origin and is much hardier than the species mentioned above. In Fla. it is usually found in all of the better parks and gardens, where it is suitable as a center about which to arrange other ornamental

shrubs. According to Nehrling, this species is of slow growth. In the male plants there are usually several heads. The male infl. is usually 18-20 in. long and cylindrical in form. The female infl. is in the form of a semi-globose head, yielding 100-200 large bright red nut-like seeds, which ripen about Christmas time. The new lvs. appear all at one time, usually in May. They have a beautiful glaucous green color and at first stand erect. Young plants are easily grown from seeds. Unfortunately this beautiful species is, in Fla., subject to blight for which no remedy has yet been found. It appears to thrive best in open situations; and in Cent. Fla., it grows with little care, flowering and fruiting abundantly. The nuts are eaten by the natives, and from the pith of the trunk a kind of sago is prepared for which the common name "sago palm" is given it. The leaves are much used in funeral decorations.

1182. Leaf of *Cycas revoluta*.

BB. *Blade of carpophylls dentate-lobate.*

**Béddomei**, Dyer (*C. revoluta*, Bedd., not Thunb.). A low shrub with sts. only a few in. high: lvs. about 3 ft. long; pinnae about  $\frac{1}{2}$  in. wide, strongly revolute; carpophylls 6-8 in. long, with the blade 3 in. long and 1 in. broad, ovate-lanceolate, tapering into a long-acuminate point, strongly dentate-lobate, bearing 2 pairs of ovules above the middle: seeds globose,  $\frac{1}{2}$  in. diam.; male cone about 1 ft. long and 3 in. diam., very short-peduncled; antheriferous scales long-acuminate, acumen in upper half of cone strongly deflexed, near the base of the cone ascending.—E. Madras, abundant on the hills.

Other cultivated cycads are *C. neo-calédonica*, Lind. "A very ornamental palm-like plant, of a different species from the cycads ordinarily grown," intro. into the U. S. by W. T. Swingle. Much like *C. circinalis* but with fronds narrower and pinnae closer.—*C. Normanbyana*, Muell., intro. into the U. S. from France by W. T. Swingle, a species with oblong-obovate lvs., having numerous linear pinnae 6 in. long. Austral.—*C. Ruminiana*, Regel. St. rather stout: lvs. bright green, erect, spreading in a vase-like crown, the pinnae fine-pointed. Philippines. I.H. 11:405.

W. E. SAFFORD.

**CYCLAMEN** (classical name, probably from the Greek word for circle, in allusion to the spirally twisted peduncles). *Primulaceae*. Herbaceous and low plants, with a flattish tuber or corm, grown sometimes in the open and one of them much prized as a florist's and window-garden subject.

Flower single, on a scape, with usually 5-parted calyx and corolla (the parts strongly reflexed), 5 connivent stamens, with pointed sessile anthers, 1 style and stigma, and a 5-splitting caps.: lvs. cordate or reniform, long-petioled, entire or sinuate-dentate: fls. nodding or declined, purple, rose or white.—About 20 species of the Medit. region, extending to Cent. Eu. *C. persicum* is the source of the standard florists' cyclamens. Most of the other species are essentially outdoor plants. They are little known in outdoor planting in N. Amer., however. The European catalogues list several species aside from *C. persicum*, and they are here described; and others are included in the supplementary list that are recently mentioned in horticultural literature. Old English name sow-bread, from the tubers being sought by swine. Consult Fr. Hildebrand, *Die Gattung Cyclamen*, Jena, 1898; also Pax & Knuth in Engler's *Pflanzenreich*, hft. 22, 1905.

All cyclamens are very beautiful, and would be much

more popular were they hardy in our eastern climate. On the Pacific slope many of them probably would be perfectly at home as outdoor plants, producing a great number of flowers above the bare soil in the depth of winter before the leaves are developed.—It is, however, with the Persian cyclamen (*C. persicum*), which is tender, that florists have had the greatest success. There is no common winter-flowering subject of as much value for duration in bloom, variety of coloring, or wealth of color. It is preferable at all times to begin the culture of Persian cyclamen with seeds, sown in the early winter months. Grow on without any check

for the following year. They should bloom freely about fifteen months from planting. Old tubers, such as are offered in fall with other florists' bulbs, rarely give satisfaction as compared with a packet of seeds. It is not the nature of the plant to have all its roots dried off, as if it were a hyacinth or tulip. Our summers are rather too warm to suit cyclamen perfectly, and it will be found that the most growth is made in the early autumn. It is best to give the plants a little shade in the hot months, such as a frame outdoors near the shade of overhanging trees at midday. This is better than growing them under painted glass, as more light is available, together with plenty of fresh air on hot days. It will be found that cyclamen seeds require a long time in which to germinate,—often two months. This is due to the fact that the seed produces a bulb or corm before leaf-growth is visible. As soon as two leaves are well developed, place the plants around the edge of 4- or 5-inch pots until every one is large enough for a 3-inch pot. The roots are produced sparingly in the initial stages, and too much pot-room would be fatal at the start. By the middle of summer another shift may be given, and in September all will be ready for the pots in which they are to flower,—5- or 6-inch pots, according to the vigor of the plants. It will always be found, however, that there will be a certain percentage that will not grow, no matter how much persuasion is used. These may be

thrown away, to save time and labor early in the season. In the house they should have the lightest bench. It is impossible to grow them in a warm, shady house. About 50° at night is the ideal temperature when in flower. The best soil is a fresh, tufty loam, with a fourth or fifth of well-rotted horse-manure, to which add some clean sand if the soil is heavy. At all times, the pots should be well drained.—The Giganteum strains of the Persian cyclamen produce the largest blooms, but at the expense of quantity. For the average cultivator it is better to try a good strain that is not gigantic. There is a recent departure in the form of crested flowers. Cyclamens come true to color from seeds, and one can now buy named varieties that will reproduce themselves almost to a certainty.—Of recent years cultivators have had much trouble with a tiny pest or mite that attacks the plants and renders them useless for bloom. Its work is done mostly after the plants are taken into the greenhouse and when about to mature into blooming specimens. If the first flowers come deformed or abnormally streaked with colors that are darker in shade, it is a sure indication that the pest is present. Frequent light fumigation with hydrocyanic acid gas as soon as the pest is discovered will in time eradicate it, but being very small, and able to hide under the divisions of the calyx, seldom coming out except on bright days, makes the pest a difficult one to fight. The gas cannot be used during sunshine. Tobacco stems used freely between the pots is a good preventive measure. Greenfly is likely to attack the

plants at all stages of growth. In the frames the plants may be plunged in tobacco stems, and in the greenhouse they must be fumigated or vaporized with some of the nicotine extracts. Great vigilance must be exercised in growing cyclamens. (E. O. Orpet.)

## A. Plant blooming in spring (or in winter under glass).

## B. Corolla-lobes not eared.

1. *persicum*, Mill. (*C. hederæfolium*, Sibth. & Smith. *C. indicum*, Linn. *C. latifolium*, Sibth. & Smith. *C. macrophyllum*, Sieb. *C. punicum*, Pomel. *C. pyrolæfolium*, Salisb.). Fig. 1183. The common greenhouse or Persian cyclamen, in many forms: tuber large, flattened endwise, corky on the outside: lvs. appearing with the fls., ovate, crenate-dentate, base deeply cordate, usually marbled or variegated with white: fls. on scapes 6-7 in. high, large, scentless, white, purple-blotched at the mouth, but with rose-colored, purple and spotted forms, the segms. oblong-spatulate in shape, not eared or lobed at the base: pedicel not coiling in fr. Greece to Syria. The large-fl. cult. forms are grouped as follows by Pax & Knuth: Var. *album* (*C. aleppicum*, Hort.). Pure white. Var. *giganteum*. White with red throat; very large. Var. *magnificum* (var. *punctatum*). White, speckled with red, large. Var. *rubrum*. Red. Var. *sanguineum*. Light blood-red, large. Var. *rosea-superbum*. Brilliant rose-red, large. Var. *purpureum*. Purple with bluish markings, large. Var. *violaceum*. Violet-red. Var. *atro-rubrum* and var. *splendens*. Dark red, large. The var. *giganteum* (*C. giganteum*, Hort.) is the common large-fl., improved form of the florist's cyclamen. There are also double-fl. forms (R.H. 1886, p. 250); also fimbriate or crested forms, *C. Papilio* (I.H. 43:63. G.F. 5:235. G.C. III. 21:71; 23:173). Other portraits of *C. persicum* are: B.M. 44. I.H. 35:43. Gn. 47:378; 48:182. J.H. III. 34:578. Gt. 44, p. 203; 45, p. 164. F.S. 22:2345. A.G. 14:390-2; 17:261. A.F. 7:521-5; 11:1176-9; 12:499. The species is frequently figured in the trade catalogues.

2. *coum*, Mill. (*C. vernum*, Sweet). Tuber smaller than in the last, globose or flattened: lvs. with or preceding the fls., nearly orbicular or round-reniform, entire, firm, not marbled nor variegated: fls. small, scentless, half or less as large as those of the last, purple and spotted in the throat. S. E. Eu. to Persia. B.M. 4. L.B.C. 2:108. F.S. 22:2345. —There is a white-fl. form (*C. album*, Hort.).

3. *ibericum*, Goldie (*C. coum* var. *ibericum*, Boiss. *C. elegans*, Boiss. & Buhse. *C. vernale*, Koch). Dwarf: lvs. appearing before the fls., ovate-orbicular and rounded at the apex, entire or obscurely undulate, more or less zoned with white above: fls. purple with a darker colored throat. Caucasus.—Perhaps a geographical form of *C. coum*. *C. Atkinsii*, Moore, is *C. coum* × *C. ibericum*, Hildeb. Lvs. reniform, apex rounded, more or less shining, deep green, spotted silver-white, the corolla-lobes pale rose or white and usually lined or spotted red. F.S. 23:2425.

## BB. Corolla-lobes eared.

4. *libanoticum*, Hildeb. Tuber globose with a cork-like covering: lvs. autumnal, the blade orbicordate, sinuate, dentate or crenulate or rarely entire, marked with white above, deep violet or purple beneath: fls. fragrant; calyx-lobes oblong-acuminate, the margin lightly undulate, 5-nerved; corolla-tube somewhat globose-campanulate, the lobes lightly eared at base and broad-ovate, entire, pale or deep rose-color with a deep red T-form mark at the base; style exserted. Lebanon.

## AA. Plant blooming in summer and autumn.

## B. Corolla-lobes not eared.

5. *europæum*, Linn. (*C. Clusii*, Lindl. *C. æstivum*, Park. *C. cordifolium*, Stokes. *C. floribundum*, Salisb. *C. orbiculatum*, and *C. purpurascens*, Mill.). Tuber with corky exterior: lvs. ovate-orbicular or reniform, entire or nearly so, with a deep and narrow basal sinus, more or less white-marbled above, purple-tinted beneath: fls. on scapes 4-5 in. high, bright red and very fragrant, not spotted; the corolla-segms. oblong-spatulate ( $\frac{3}{4}$  in. or less long); calyx glabrous: pedicel spirally coiling in fr. Cent. and S. Eu. B.R. 1013.—Lvs. appearing with the fls., more or less evergreen. Variable.

6. *cilicicum*, Boiss. & Heldr. Much like *C. europæum*: tuber hairy: fls. pale rose, with purple at the mouth, about twice larger; corolla-lobes elongated; calyx puberulent. Sicily. G.C. III. 23:81.

## BB. Corolla-lobes eared.

7. *africanum*, Boiss. & Reut. (*C. saldense*, Pomel). Large: tuber large: lvs. ovate-cordate to reniform, coarsely toothed, pale beneath, dull and pale green marbled above: calyx pubescent, the lobes broadly ovate-acuminate; corolla nearly white, faintly rose- or purple-tinged, the segms. 1 in. long and deep purple at the base; calyx-lobes lanceolate. Algeria. B.M. 5758. F.S. 8:841.—Little known in this country, but sold by the American agencies of the Dutch bulb houses.

8. *neapolitanum*, Tenore (*C. autumnale*, Boos. *C. ficariæfolium* and *C. subhastatum*, Reichb. *C. hederifolium*, Ait. *C. vernale*, Mill.). Tuber very large, black, thick-rinded: lvs. variable, from hastate to round-reniform, more or less wavy-plaited on the edges, green or somewhat parti-colored: calyx small; corolla pink or rarely white, the segms. short and twisted and the edges raised and white-edged at the base; calyx-lobes triangular to oblong. S. and E. Eu. B.R. 24:49. Gn. 51, p. 37

1183. *Cyclamen persicum*. Showing a flower of perfect form, and the crested variety. ( $\times \frac{1}{2}$ )

*C. aquileticum*, Hildeb. Intermediate between *C. græcum* and *C. pseudo-græcum*; from the former it differs in its small fls. and other parts and from the latter in having more rounded lvs. Greece. —*C. græcum*, Link. Autumn-flowering: lvs. obcordate, irregularly cartilaginous-dentate: corolla-lobes lanceolate or oblong-lanceolate, eared at base, rose-colored with deep purple at base. S. E. Eu. —*C. hiemale*, Hildeb. Winter-flowering: lvs. round-reniform, bright green and silver-zoned: fl. purple with deep red in the throat; corolla-lobes round-ovate, not eared. Asia Minor. —*C. Jovis*, Hildeb. Differs from *C. neapolitanum* in its more slender fls. with longer lobes of calyx and corolla. Asia Minor. —*C. maritimum*, Hildeb. Lvs. variable in form, mostly ovate, brown-green: fls. in Sept., inconspicuous, pale rose with marked throat, the corolla-lobes rounded. Asia Minor. —*C. Meliarskii*, Hort. = *C. græcum*. —*C. pseudo-græcum*, Hildeb. Differs from *C. græcum* in having filaments and anthers longer, the latter 3-angled and acuminate: corolla pale rose or almost white. Crete. —*C. pseudo-ibericum*, Hildeb. Spring-flowering: lvs. obcordate, rounded at base and top, the margin cartilaginous-crenulate, deep green and spotted silvery white: fl. violet, spotted with darker color, white at base; corolla-lobes oblong-ovate, not eared; pedicel spiral in fr. Probably Asia Minor. —*C. pseudo-maritimum*, Hildeb. Differs from *C. maritimum* in lvs. being lanceolate-acuminate, calyx-lobes rounded and corolla-lobes long-acuminate. Asia Minor. —*C. repandum*, Sibth. & Smith. Spring-flowering: tuber small: lvs. cordate, undulate-lobed, the lobes usually mucronate: fl. beautiful purple, the throat constricted and deeper-colored. Cent. and E. Medit. basin. L. H. B.

**CYCLANTHÈRA** (Greek, *anthers in a circle*). *Cucurbitaceæ*. Annual- or perennial-rooted herbs, one of which is sometimes grown for its ornamental character.

Climbing by tendrils, glabrous or pubescent: lvs. entire, lobed or 5-7-foliolate: fls. monœcious, minute, yellow, greenish or white, with their parts in 6's, stamen 1 with a 1-celled anther. The plant is a climbing half-hardy annual of easy cult. The seed should be started indoors early. The genus is near *Echinocystis* and *Elaterium*, and has more than 30 species, all from Trop. Amer.

*pedata*, Schrad. Annual: st. glabrous: lvs. pedately 5-7-foliolate, the lfts. sessile or nearly so and lanceolate or oblong-lanceolate, serrate: tendrils 3-4-parted: male fls. small, in panicles equaling or exceeding the lvs.: fr. nearly sessile, somewhat soft-prickly or smooth, oblong and attenuate at base, green becoming yellowish white, 2-locular. Mex. south.—A strong ornamental climber. *C. explodens*, Naudin, with somewhat 3-lobed lvs. and short spiny explosive fr., may be in cult. L. H. B.

**CYCLÁNTHUS** (*flowers in a circle*). *Cyclanthaceæ*. A Trop. American genus of 4 species giving name to a small order which is allied to the palms. They are acaulescent palm-like herbs with a milky juice: lvs. long-stalked, entire or bi-furcate, the segms. lanceolate, 1-nerved: fls. fragrant. The species are not in the American trade. Cult. of *Carludovica* (which see). *C. bipartitus*, Poit., of Guiana, has lvs. sometimes divided into 2 long narrow lobes, the petioles being 3-6 ft. long: spadix straight and cylindrical, in a 4-lvd. yellow spathe, the scape 2 ft. long. G.W. 8, p. 153; 15, p. 610. *C. cristatus*, Klotzsch, of Colombia, has short-stalked bifid lvs., with the parts falcate and connivent: spadix about 8 in. long. G.W. 8, p. 202. *C. discolor*, Hort., has young lvs. streaked with brown-orange: lvs. bifid, the parts lanceolate, acuminate, the margins frilled. Probably S. Amer. *C. Godseffianus*, Hort., exhibited in 1892, "has noble lvs. of a rich green color, oblong, obovate, tapering to a sheathing stalk." Sander.

**CYCLOBÔTHRA**: *Calochortus*.

**CYCLOLÔMA** (Greek for *circle and border*, from the encircling wing of the calyx). *Chenopodiaceæ*. One weedy herb, *C. atriplicifolium*, Coulter (*C. platyphylum*, Moq.), of sandy soils from Minn., west and south, which was once intro. as the "cyclone plant," since the plant is a tumble-weed or rolls before the wind when it is matured and becomes detached from the soil. The plant is a much-branched rank-growing annual, 1-2 ft. high, pubescent or nearly glabrous, with narrow but flat and sinuate lvs., and bractless fls. in an open panicle. The fls. are very small, perfect or sometimes

lacking the stamens; calyx 5-cleft, the lobes strongly keeled and becoming winged and inclosing the seed. Plant not fleshy or jointed.

**CYCLÓPHORUS** (Greek, *circle-bearing*). *Polypodiaceæ*. An E. Indian and Malaysian genus of simple-lvd. ferns, related to some species of *Polypodium*. The genus is characterized by having creeping scaly root-stocks, simple lvs. usually densely covered with star-shaped scales, at least on the back. The sori are round, naked, and placed so closely together as to appear often completely to cover the back of the lf. The venation consists of a very fine close network difficult to distinguish. Often listed in trade under *Polypodium*.

*Lingua*, Desv. (*Niphobolus Lingua*, Spreng.). Lvs. 6-12 in. long, on short stalks, the lf.-blades thick, leathery, narrowly oblong, 4-8 in. long, 1-2 in. broad, densely covered beneath with rusty white scales. Var. *corymbifera*, Hort. A form with the tips of the lvs. much forked, making the blade much broader than in the type. Var. *variegata*, Hort. A form with "light yellow lines about 1/8 in. wide and 3/4 in. apart, running across the fronds at right angles to the midrib." See also *Polypodium*. R. C. BENEDICT.

**CYCNOCHES** (Greek, *swan's neck*, referring to the shape of the column). *Orchidaceæ*. Epiphytic orchids, requiring warmhouse treatment when growing.

Pseudobulbs fusiform: lvs. plicate: fls. of 2 sexes, the perianth alike, the lip entire, or that of the staminate very different, with the sepals and petals narrower, the lip clawed and with finger-like projections from the side, the column much elongated and arched; pollinia 2. Both sexes may be produced in the same plant. A third form of fl., usually perfect, occasionally appears; this is intermediate between the others.—About a dozen species of Trop. Amer.

A. *Perianth alike in both sexes; lip entire.*

*chlorochilon*, Klotzsch. Pseudobulbs 5-7 in. tall: lvs. lanceolate: raceme erect, 2- or 3-fld.; fls. 4-6 in. across; sepals and petals yellowish green, acute, the lateral sepals broader than the dorsal; lip obovate or elliptic, acute, a dark green depression near the triangular erect callus. Venezuela. G.C. III. 3:145. I.H. 35:65. R. 1:39. J.H. III. 35:285. Gn. 49, p. 403; 51:172.

*ventricosum*, Batem. Pseudobulbs 8-10 in. tall: lvs. lanceolate: raceme drooping, 4-6-fld.; fls. 4-5 in. across; sepals and petals yellowish green, acute, the petals broader than the sepals; lip white, cordate, acuminate, clawed, a black callus at the junction of the claw with the lip. Guatemala.

AA. *Perianth differing in the sexes; lip with finger-like lateral projections.*

*aureum*, Lindl. Male racemes pendulous, 8-12-fld.; fls. 2-3 in. across, yellow, red-spotted; sepals and petals similar, the former spreading, the latter reflexed; lip clawed, the dilated middle giving rise to a number of projections, forked at the end. Cent. Amer. J.F. 3:264.

*pentadactylon*, Lindl. Male racemes usually pendulous, many-fld.; sepals and petals greenish yellow barred with brown; lip white, red-spotted, with 5 finger-like projections; female racemes erect, few-fld.; sepals and petals broader than in the male fls., spotted; lip ovate, entire. Brazil. B.R. 29:22. J.H. III. 62:305. O.R. 8:312.

*peruviana*, Rolfe. Male racemes pendulous, many-fld.; sepals and petals light green, copiously brown-spotted; lip, with its projections, white. Peru. Lind. 7:301.

*C. densiflorum*, Rolfe. Male racemes pendulous, many-fld., the fls. greenish with purple blotches; female racemes short, erect, 2-fld., the sepals and petals green, the lip ivory-white. Colombia. O.E. 17:204; 20:331. B.M. 8268.—*C. maculatum*, Lindl. Male racemes pendulous, the sepals and petals light yellowish green, spotted with red-purple, the lip white. Mex. O. 1910:104. O.R. 17:273; 20:315.

(GEORGE V. NASH.)

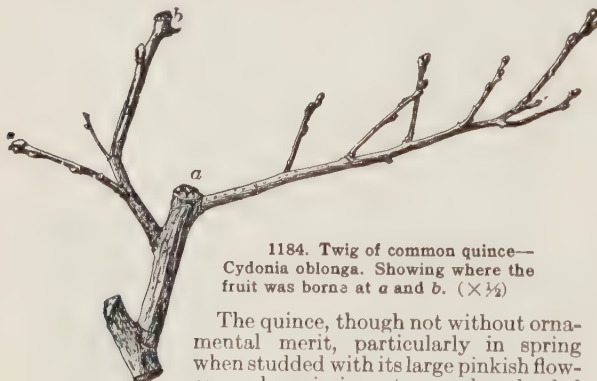

**CYDISTA** (Greek, *kydistos*, most glorious; alluding to the beautiful flowers). *Bignoniaceæ*. Ornamental vines, grown for their beautiful flowers.

Evergreen shrubs, climbing by lf.-tendrils: lvs. opposite, with 2 lfts., the rachis elongated into a simple slender tendril, sometimes wanting: fls. in terminal or axillary panicles, sometimes 2; calyx campanulate-turbinate, truncate or with 5 short teeth; corolla funnel-form-campanulate, with imbricate lobes; stamens 4, inclosed, with spreading anther-cells; disk wanting; ovary linear, with numerous ovules in 2 rows: caps. linear, septicid, with numerous, nearly orbicular, winged seeds.—One or 2 species in the W. Indies and S. Amer. Closely allied to *Bignonia*, but easily distinguished by its simple slender tendrils, by the paniculate fls., the usually truncate calyx and the wanting disk. Suited for cult. in tropical and subtropical regions only and as a stove plant in the N. For cult. and prop., see *Bignonia*.

*æquinoctialis*, Miers (*Bignonia æquinoctialis*, Linn.). High climbing: lfts. ovate to ovate-oblong, obtuse-acuminate, undulate, lustrous, reticulate, 3-4 in. long; petioles  $\frac{1}{8}$ - $\frac{3}{4}$  in. long; calyx campanulate-turbinate, truncate; corolla white or pink, with dark pink or purplish veins,  $2\frac{1}{2}$  in. long. W. Indies, Brazil.—The *B. æquinoctialis* var. (B. R. 9:741) with yellow fls. in elongated racemes is *Anemopaegma Chamberlaynii*, Bur. & Schum. (*Bignonia Chamberlaynii*, Sims B. M. 2148. F. S. 3:235. P. M. 14:3.). See page 502. ALFRED REHDER.

**CYDONIA** (the fruits known to the Romans as *Mala Cydonia*, apples from Cydon, now Canea, in Crete). *Rosaceæ*, subfamily *Pomææ*. QUINCE. Shrub or small tree, grown for its fruit, which is much used for preserves and sometimes baked.

Branches unarmed: lvs. deciduous, alternate, petioled, stipulate, entire: fls. white or light pink, rather large, terminal on short leafy branchlets; petals 5; stamens numerous; styles 5, free; ovary 5-celled, cells with many ovules; fr. a 5-celled, many-seeded pome.—One species from Persia to Turkestan. The genus *Chenomeles*, often included under *Cydonia*, is easily distinguished by the serrate or crenate chartaceous lvs. and the connate styles.

1184. Twig of common quince—*Cydonia oblonga*. Showing where the fruit was borne at a and b. ( $\times \frac{1}{2}$ )

The quince, though not without ornamental merit, particularly in spring when studded with its large pinkish flowers and again in autumn when loaded with its golden fragrant fruits, is rarely planted as an ornamental shrub, but chiefly, though not very extensively, grown for its fruit which is made into preserves. It is of slow growth and prefers heavy and rather moist soil. It may be propagated by seeds stratified and sown in spring, but is usually increased by cuttings of one to four-year-old wood, taken in fall and stored until spring in sand or moss in a cellar or frame; also by layers and budding, or by grafting on vigorous growing varieties. See *Quince*.

*oblonga*, Mill. (*C. Cydonia*, Pers. *C. vulgaris*, Pers. *Pyrus Cydonia*, Linn.). QUINCE. Fig. 1184. Shrub or small tree to 15, rarely to 25 ft., with slender, spineless

branches: lvs. oval or oblong, rounded or slightly cordate at the base, acute, entire, villous-pubescent beneath, 2-4 in. long: fls. white or light pink, 2 in. across: fr. large, yellow, villous, pyriform or globular. May; fr. in Sept. and Oct. Cent. and E. Asia. Gn. 33, p. 491. F. S. R. 2, p. 379: 3, p. 283. Seeds have mucilaginous and demulcent properties. Var. *pyriformis*, Rehd. (*C. vulgaris* var. *pyriformis*, Kirchn.) Fr. pear-shaped, the typical form. Var. *lusitanica*, Schneid. (*C. lusitanica*, Mill.). Fr. pear-shaped and ribbed: lvs. larger; of more vigorous growth. Var. *maliformis*, Schneid. (*C. maliformis*, Mill.). Fr. apple-shaped. Var. *pyramidalis*, Schneid. Of pyramidal habit. Var. *marmorata*, Schneid. Lvs. whitish and yellow variegated. For pomological varieties, see *Quince*.

For *Cydonia japonica*, Pers., *C. Maulei*, Moore, and *C. sinensis*, Thouin, see *Chenomeles*.

ALFRED REHDER.

**CYMBIDIUM** (*boat*, from the Greek, referring to the shape of the lip). *Orchidaceæ*. Handsome epiphytal, rarely terrestrial orchids, requiring greenhouse conditions.

Stems pseudobulbous or not so: lvs. coriaceous, long, rarely short, persistent: sepals and petals sub-equal, labellum usually tri-lobed, adnate to the base of the column; column erect; pollinia 2.—Species 30 and more, tropical or subtropical, found on mountains at high elevations in Asia, and a few species in Afr. and Austral.

These are among the most decorative of orchids when in bloom, and are attractive all the time owing to the graceful foliage seen on well-grown specimens. There are now many handsome species and varieties and these in their turn have produced, at the hands of the hybridizer, many fine decorative plants, so that a house of cymbidiums produces flowers most of the time, and these last many weeks in full beauty. There are few orchids whose flowers last so long, and the spikes of bloom, often 2 to 3 feet in length, are useful for decorative purposes of all kinds, either on the plants or cut. The recent species, *C. insignis*, is the most beautiful of all and has already lent itself to hybridization, so that to the very many known hybrids *C. insignis* will soon add its influence and coloring.—Cultivated cymbidiums are terrestrial, with thick fleshy roots best contained in pots. A portion of tough fibrous loam should be added to the osmundine, about half of each with plenty of broken charcoal to keep the whole porous. The plants will do well for years without disturbance at the roots, but when this is necessary, great care must be taken not to injure them. Division is, in fact, very difficult to accomplish when the pots are full of roots, and it is best practice to pot the plant in a larger receptacle if the roots are healthy, washing out loose earth and removing dead portions of roots first. Cymbidiums may be grown in a temperature of 50° as a minimum in winter, must not be subjected to strong sunlight after March, and never allowed to become dry at the roots, as these are more or less active, even in winter. Being terrestrial, weak manure-water may be applied during active growth. Many species thrive well when planted out in large palm and fern houses among rocks arranged in a natural manner, and when the plants are placed so that the flower-spikes are on a level with the vision, they have a charming effect for many weeks when in bloom, and the environment suits them well. Of the few well-marked species, there are many forms that have been collected and when flowered in cultivation, proved distinct. These in some cases have been called new species, but are now being better understood; some prove to be natural hybrids, others are varieties. (E. Ö. Orpet.)

A. Fls. white.

*eburneum*, Lindl. Sts. tufted: lvs. distichous at base, 1 or 2 ft. long, linear or lorate, bifid at apices;

peduncles not so long as the lvs., few-fl'd.; fls. about 3 in. across, ivory-white, sometimes tinged with rose; sepals and petals oblong-lanceolate; lip 3-lobed with a golden yellow ridge running down the center. Khasia Hills, at an elevation of 5,000-6,000 ft. B.R. 33:67. B.M. 5126. Gn. 46, p. 398. G.C. III. 35:99. Var. *Goodsonianum*, Hort. Fls. white, with broad rose-purple band down middle of lip. Var. *Dayanum*, Hort. (*C. Dayanum*, Reichb. *C. eburneum* Dayi, Jenm.). Lvs. longer and narrower; lip with a row of purple spots each side of disk.

1185. *Cymbidium giganteum*. ( $\times \frac{1}{3}$ )

AA. Fls. not white.

B. Infl. arching or erect.

c. Sepals and petals veined with red, brown or purple.

d. Ground-color of sepals and petals not white.

E. Middle lobe of lip purple-maroon, margined yellow.

**Lowianum**, Reichb. f. Pseudobulbs oblong; lvs. 2-3 ft. long, linear-acute, recurved; racemes many-fl'd.; fls. about 20 in number, 3-4 in. across; sepals and petals oblong-lanceolate (lateral ones sub-falcate), greenish yellow marked with brown; lateral lobes of lip yellowish; midlobe reflexed, purple-maroon, margined with yellow. Burma. Gn. 48, p. 263. Gng. 5:73. A.F. 34:1089. R.B. 30:276. Var. *Mandaiianum*, Hort. (*C. Mandaiianum*, Hort.), has yellow fls.

EE. Middle lobe of lip yellow, spotted.

**giganteum**, Wall. Fig. 1185. Fls. dull purple (brownish, or yellowish green striped with purple); sepals and petals oblong, the petals narrow and shorter; midlobe of lip reflexed, yellow, spotted with red; lateral lobes yellowish green. Nepal. B.M. 4844. P.M. 12:241.

**Traceyanum**, Hort. Pseudobulbs and foliage as in *C. giganteum*; racemes 3-4 ft. long, ascending, 15-20 fl'd.; fls. 4-5 in. across; sepals and petals greenish yellow, lined with crimson; middle lobe of lip oblong, reflexed, crisped, cream-white, crimson-spotted. Burma. C.O. 4. R.B. 29:25.—By some considered a natural hybrid between *C. grandiflorum* and *C. giganteum*.

DD. Ground-color of sepals and petals white, flushed rose.

**insigne**, Rolfe (*C. Sanderi*, Hort. *C. insigne Sanderi*, Hort.). Lvs. up to 3 ft. long; infl. long, ascending; fls. rosy white; sepals and petals elliptic; lip marked with lines of purple dots, the middle lobe short, obtuse, emarginate; disk yellow. C.O. 10. B.M. 8312. O. 1911:64. R.B. 33:53. R.H. 1907:496. G.C. III. 37:115.

cc. Sepals and petals not veined.

**tigrinum**, Parish. Lvs. oblong-lanceolate; peduncles slender, 3-6 fl'd.; sepals and petals linear-oblong, acute,

green, spotted at base; petals often paler and with more spots than the sepals; lip with yellow, red-brown striped lateral lobes; midlobe white, transversely streaked with purple. Burma. B.M. 5457. A.G. 22:715.

**grandiflorum**, Griff. (*C. Hookerianum*, Reichb. f.). Lvs. about 2 ft. long, acute; peduncle arching above, erect at base; fls. from 6-12, large, sepals and petals oblong, greenish; lip yellow, spotted with purple. Sikkim. B.M. 5574.

BB. Infl. pendulous.

**pendulum**, Swartz. The leathery lvs. distichous, 2-3 ft. long, broadly linear; fls. yellowish; side lobes and midlobe of lip rose-color; the disk more or less white with yellow crests; sepals and petals narrowly oblong, with a purple median line. E. Indies.

**Finlaysonianum**, Lindl. (*C. pendulum*, Lindl.). Lvs. ensiform; raceme many-fl'd.; sepals and petals linear-oblong, obtuse, dull yellow, sometimes with a reddish median line; lateral lobes of lip crimson; midlobe white, tipped with crimson. Malaysia. Var. *atropurpureum*, Hort. Lvs. narrower, racemes longer, with larger fls.; sepals and petals purplish, front lobe of lip white, spotted with purple. Borneo.

*C. Alexandri*, Hort. Hybrid between *C. eburneo-Lowianum*  $\times$  *C. insigne*.—*C. aloifolium*, Swartz. Racemes many-fl'd., arched; fls. pale purple, black-striped. E. Indies. *C. Ballianum*, Hort. Natural hybrid between *C. eburneo*  $\times$  *C. Mastersii*.—*C. Colmanae*, Hort. Hybrid between *C. eburneo-Lowianum*  $\times$  *C. eburneo*  $\times$  *C. Cravenianum*, Hort. Hybrid between *C. Lowianum*  $\times$  *C. Traceyanum*.—*C. Devonianum*, Paxt. Racemes many-fl'd., pendulous; sepals and petals greenish or reddish yellow, spotted or lined with purple; lip purple. India. C.O. 8.—*C. eburneo-giganteum*, Hort. Hybrid between *C. eburneo*  $\times$  *C. giganteum*.—*C. eburneo-Lowianum*, Hort. Hybrid between *C. eburneo*  $\times$  *C. Lowianum*.—*C. ensifolium*, Swartz. Lvs. ensiform, acute; racemes many-fl'd.; fls. greenish yellow, purple-veined; sepals and petals linear-oblong, acute; lip spotted. India. Japan. B.M. 1751.—*C. erythrostylum*, Rolfe. Sepals and petals white; lip yellowish white, lined red-purple; column crimson. Annam. B.M. 8131. G.C. III. 40:286.—*C. galtonense*, Hort. Hybrid between *C. Lowianum*  $\times$  *C. Traceyanum*.—*C. Gammiesianum*, Rolfe. Supposed to be a natural hybrid between *C. giganteum*  $\times$  *C. elegans*. G.C. III. 38:427.—*C. glebeldandense*, Hort. Hybrid between *C. Schraderi*  $\times$  *C. insigne*.—*C. Gottianum*, Hort. Hybrid between *C. eburneo*  $\times$  *C. insigne* Sanderi. Fls. white, the sepals with a faint greenish tinge, the lip blotched with ruby-purple. G.C. III. 49:180.—*C. Holfordianum*, Hort. Hybrid between *C. grandiflorum*  $\times$  *C. eburneo*.—*C. Holmesii*, Hort. Hybrid between *C. Mastersii*  $\times$  *C. giganteum*.—*C. Huttonii*, Hook. f. = *Grammangis*.—*C. langleyense*, Hort. Hybrid between *C. Lowianum*  $\times$  *C. Devonianum*. Sepals and petals greenish brown, the lip marked with reddish brown. G.C. III. 49:146.—*C. Lindleyi* (?).—*C. longifolium*, Don. Lvs. linear, acuminate; racemes suberect; fls. about 12; sepals and petals green, striped brownish purple, the sepals oblong, the dorsal one broader and incurved; lip with the lateral lobes purple-lined, the middle lobe and disk white. Himalayas. G.M. 54:472.—*C. lowianum*, Hort. Hybrid between *C. Lowianum*  $\times$  *C. tigrinum*.—*C. Lóvi-grandiflorum*, Hort. Hybrid between *C. Lowianum*  $\times$  *C. grandiflorum*.—*C. Lóvi-Mastersii*, Hort. Hybrid between *C. Lowianum*  $\times$  *C. Mastersii*.—*C. Mastersii*, Griff. = *Cyperorchis*.—*C. Párisii* var. *Sánderei*, Rolfe (*C. Sanderi*, Hort.). Sepals and petals ivory-white, the front lobe of lip heavily blotched with crimson-purple, the crests orange-yellow. Burma. G.C. III. 35:338.—*C. Pavluetsii*, Hort. = *C. insigne*  $\times$  *C. Lowianum* concolor. —*C. pumilum*, Rolfe. Scape 4-6 in. long, many-fl'd.; sepals light reddish brown; lip white with red-brown spots; disk and keels bright yellow. China.—*C. rhodochilum*, Rolfe. A striking plant; raceme many-fl'd.; sepals and petals pale green; the latter with darker green spots; lip with the lateral lobes pale green, margined crimson, the middle lobe obovate, crimson, with a yellow central band which is green-spotted. Madagascar. B.M. 7932-3. O.R. 14:209. A.F. 18:810. G.C. III. 37:378. Gn. 61, p. 383.—*C. roseifolense*, Hort. Hybrid between *C. Traceyanum*  $\times$  *C. grandiflorum*.—*C. Sándersonii* = *Ansellia*.—*C. Schraderi*, Rolfe. Petals and sepals lanceolate, green, lined and dotted with reddish brown; lip light yellow striped with brown. Annam.—*C. Simonsianum*, Ruiz & Prantl. Sepals and petals grayish white, streaked blood-red in the center; lip white, streaked blood-red, the middle lobe revolute, with a yellow blotch. Assam. B.M. 7863.—*C. Steppedunum*, Pynart. Hybrid between *Cyperorchis* *Mastersii*  $\times$  *Cymbidium* *giganteum*. Sepals and petals yellowish green, the lip white marked brown and yellow. R.B. 36:397.—*C. Veitchii*, Hort. Hybrid between *C. eburneo*  $\times$  *C. Lowianum*. Fls. fragrant, about 5 in. across; sepals and petals white, tinted yellow; lip white, tinted yellow, with a large Y-shaped purple-crimson spot on the middle lobe. G.C. III. 47:407. O.R. 12:369; 16:325. C.O. 1.—*C. viridescens*, Lindl. Sepals and petals greenish, the lip yellow, red-blotched. Japan.—*C. Wiganianum*, Hort. Hybrid between *C. eburneo*  $\times$  *C. Traceyanum*.—*C. Wilsonii*, Hort. Sepals and petals green, indistinctly marked at base with lines of reddish dots; lip cream, the lateral lobes lined with sepia-brown and reddish markings on the front lobe. China. G.C. III. 35:157.—*C. Winnianum*, Hort. Hybrid

between *C. giganteum* × *C. eburneum*. Racemes 10-15-fl.; fls. about 4 in. across; sepals and petals ivory-white; lip ivory-white, spotted with crimson. O.R. 1:361; 12:369. G.M. 51:179.—*C. Woodhamsianum*, Hort. Hybrid between *C. Lowianum* × *C. Veitchii*. G. 30:107.—*C. woodlandense*, Hort. Hybrid between *C. Traceyanum* × *C. Mastersii*.—*C. Zaleskianum*, Hort. Natural hybrid between *C. giganteum* × *C. grandiflorum*.

GEORGE V. NASH.†

**CYMBOPÉTALUM** (Latin, signifying *boat-petal*, from the shape of its petals). *Annonaceæ*. A group of plants remarkable for the fragrance of their aromatic flowers.

Flowered with the 3 inner petals having the margin incurved somewhat like the upper part of the human ear, the several-ovuled carpels forming a cluster issuing from a globose mass of stamens: fr. in the form of separate oblong berries borne on the hardened torus or receptacle and resembling that of our papaw (*Asimina triloba*).—Several species, all of them endemic in Trop. Amer. Among the species thus far described are *C. brasiliensis*, Benth. (*Uvaria brasiliensis*, Velloso). *C. penduliflorum*, Baill. (*Unona penduliflora*, Dunal). *C. longipes*, Diels, and *C. stenophyllum*, Donnell Smith.

*penduliflorum*, Baill. XOCHINACAZTLI. TEONACAZTLI. SACRED EARFLOWER of the Aztecs. OREJUELA. FLOR DE LA OREJA. MEXICAN EARFLOWER. Figs. 1186, 1187. A shrub or small tree with distichous, membranaceous, subsessile lvs. oblanceolate in form, subcordate and usually unequal at the base, acute at the apex: solitary fls. borne on long slender peduncles issuing from the internodes of the smaller branches; sepals broadly ovate or suborbicular, cuspidate, reflexed at length; outer petals similar to the sepals but much larger; inner petals thick and fleshy, their margin involute, causing them to resemble a human ear.—The pungently aromatic fls. when fresh are greenish yellow, with the inner surface of the inner petals inclining to orange-color, at length turning brownish purple or maroon, breaking with a bright orange-colored fracture. The tree is planted for the sake of its fragrant fls., the petals of which are dried and are used medicinally as well as for imparting a spicy flavor to food. They were used by the ancient Mexicans before the intro. of cinnamon and other spices from the E. Indies for flavoring their chocolate. Though described by Hernandez more than two centuries ago, the botanical identity of the xochinacaztli remained unknown until quite recently (see Smithsonian Report for 1910, pp. 427-431, 1911). This species is native of the mts. of S. Mex. and Guatemala. A closely related species, *C. stenophyllum*, Donnell Smith, was discovered by Capt. John Donnell Smith in the Dept. of Quetzaltenango, Guatemala; and another species, *C. costaricensis*, Safford (*Asimina costaricensis*, Donnell Smith) was collected by Adolfo Tonduz in the Dept. of Talamanca, Costa Rica, in April, 1894. Steps have been taken by the Bureau of Plant Industry to intro. into

the U. S. *C. penduliflorum*, seeds of which have been sent from Guatemala by the American Consul-General, George A. Bucklin. The other Cent. American species, as well as *C. brasiliense*, recently collected by Henry Pittier in Venezuela, are equally worthy of cult. in greenhouses and in the warmer regions of Fla., Calif. and the Island possessions.

W. E. SAFFORD.

**CYMBOPÔGON** (Greek *kumbo*, a cup, and *pogon*, beard). *Gramineæ*. Oil-producing grasses.

The genus resembles *Andropogon*, of which it is considered by some a subgenus, but differs in having some of the lower pairs of spikelets in each spike staminate. The spike-like racemes are borne in pairs at the ends of the short branches of the infl. and are subtended by a somewhat inflated sheath.—About 40 species, mostly of the tropics of the Old World. Several species furnish essential oils and some are cult. for that purpose. They are known under the general name of oil grasses or lemon grasses. Some of the more important are: *C. Schenanthus*, Spreng. CAMEL HAY. Fig. 1188. G.W. 14:399; *C. Nardus*, Rendle. CITRONELLA GRASS. Gn. 12:495; *C. citratus*, DC. LEMON GRASS. Gn. 12:495. For a full account of these, see Kew Bull. Misc. Inf. No. 8, 1906. See also *Vetiveria*.

A. S. HITCHCOCK.

**CYNÁNCHUM** (Greek, *dog strangle*). *Asclepiadaceæ*. Herbaceous or sometimes half woody at the base, twining, sometimes seen in gardens.

In the restricted sense as limited by Bentham & Hooker, perhaps 25 species differing from *Vincetoxicum* in having a scale or ligule on the inside of each of the 5 parts of the crown: lvs. opposite, cordiform or hastate; fls. small, in umbelliform or racemiform cymes; calyx 5-parted; corolla nearly rotate, deeply 5-cut, the lobes oblong or roundish; corona membranaceous, adnate to the stamens, tube, cup-shaped or at base ringed, 5-lobed opposite the anthers and with inner scales or small lobes: follicles rather fleshy, acuminate and smooth.—The genus is mostly of S. Eu., Afr., Asia and Austral. Schumann in Engler & Prantl combines *Vincetoxicum* and other genera with it, making more than 100 species in the warmer parts of both hemispheres. *Vincetoxicum* is here kept distinct.

*acuminatifolium*, Hemsl. (*Vincetoxicum acuminatum*, Deene. *V. japonicum*, Hort.). MOSQUITO PLANT. CRUEL PLANT. Perennial: erect or nearly so, or the tips showing a somewhat twining habit: sts. grayish and more or less angular: lvs. opposite, broadly ovate and acuminate, short-petioled, strongly pinnate-veined, entire, usually conspicuously gray-pubescent beneath:

1186. *Cymbopetalum penduliflorum*. (× ½)

1187. *Cymbopetalum penduliflorum*.

fl.-clusters lateral (1-2 between the lvs.), shorter than the lvs.; fls. white, small, in umbel-like cymes: fr. a milkweed-like follicle. Japan.—In the fls. mosquitos and other insects are caught, much as they are in other asclepiadaceous plants. The native *Amsonia Tabernaemontana* is sometimes sold as this plant, and it has been figured as such. This plant attracted attention some years ago as a curious garden subject. Other species are mentioned in foreign gardening literature, but they are apparently not in the American trade. *C. acutum*, Linn., with cordate smooth lvs. and white or rose-colored fragrant fls., is a climber in S. Eu., reaching 10 or 12 ft. *C. formosum*, N. E. Br., is glabrous, with petiolate ovate, elliptic or oblong-ovate acuminate lvs.: fls. in large lateral pedunculate cymes; corolla pale green, deeply lobed; corona tubular - bell-shaped, 15-crenulate, prominent. Peru.

L. H. B.

**CYNARA** (involucre spines likened to a dog's tooth). *Compósitæ*. ARTICHOKE and CARDOON.

Thistle-like perennial herbs, mostly coarse, and sometimes prickly: lvs. commonly large, variously lobed or pinnatisect; head large, terminating important branches, the corollas violet, blue, or white; involucre broad or nearly globular, with bracts in many series and more or less enlarged at the base; receptacle fleshy and plane, bristly; corolla slender-tubed, 5-parted, not ligulate: fr. a thick glabrous compressed or 4-angled achene with a truncate apex.—Ten or a dozen species in the Medit. region and Canary Isls., two of which are grown as garden vegetables.

**Cardunculus**, Linn. CARDOON (which see). Robust, to 6 ft. tall and more: st. grooved: lvs. very large, deeply pinnatifid, grayish green above and whitish beneath, prominently spiny: heads purple-fl., with sharp-pointed scales. S. Eu., but extensively run wild on the pampas of S. Amer. B.M. 3241.—In cult., the thickened lf.-stalks or ribs are blanched and used as a pot-herb, and the root is also edible.

**Scôlymus**, Linn. ARTICHOKE (which see). Not so stout, usually 3-5 ft.: lvs. less pinnatifid and spiny: scales of involucre broad, thickened at base, unarmed: heads larger than in *C. Cardunculus*, the receptacle enlarged and fleshy.—Probably a derivative of the last.

L. H. B.

**CYNODON** (Greek *kuon*, a dog, and *odons*, a tooth). *Graminææ*. Low creeping perennials, used for lawns and pasture.

Flowers in slender digitate spikes; spikelets 1-fl., compressed, awnless, sessile in 2 rows along one side of a slender rachis.—Species 4, in warm regions.

**dáctylon**, Pers. (*Capriola dáctylon*, Kuntze). BER-MUDA-GRASS. WIRE-GRASS. Fig. 1189. Sts. flattened, slender, creeping and rooting at the nodes, producing numerous slender or stout creeping root-stocks: blades hairy around the base: spikes 4-5, 1-1½ in. long. Dept. Agric., Div. Agrost. 20: 99.—A native of the warmer parts of the Old World, now widely distributed in the warmer parts of the western hemisphere. Cult. as a pasture and lawn grass in the southern states. Often a troublesome weed in cult. ground. A fine-ld. form with runners above ground, much used in the S. for lawns, is called St. Lucie grass. In Eu. the stolons are said to be used medicinally like couch-grass, principally as a diuretic.

*C. incompletus*, Nees. BLUE COUCH-GRASS. Occurs in E. and S. Afr. and also New S. Wales, where it is used as a pasture grass. It is reported as poisoning stock, at certain stages of its growth producing hydrocyanic (prussic) acid.

A. S. HITCHCOCK.

## CYNOGLOSSUM

(Greek, *hound's tongue*, from the shape and soft surface of the lvs. of the commonest species). *Borraginææ*. A widely dispersed genus of little horticultural interest, being mostly tall, coarse, weedy herbs. Lvs. alternate: fls. always in elongated, often 1-sided racemes.—Species 75. *C. officinale*, Linn., Fig. 1190 (stick-tight), has a bur that becomes attached to clothing and to fleece of sheep. It is a biennial weed, naturalized from the Old World;

1188. *Cymbopogon Schoenanthus*. (×½)

grows about 2 ft. high in pastures and waste places of the Atlantic states, and has soft-pubescent, lanceolate lvs., and dull red-purple (sometimes white) fls. in panicle racemes. Root and herbage possess medicinal properties. *C. grande*, Douglas. Once cult. from Calif.

as a hardy border perennial; grows about 2 ft. high, with lower lvs. ovate-oblong, or somewhat heart-shaped at the base, acute or acuminate, 4-8 in. long, on margined petioles

of about the same length: upper lvs. smaller, ovate to lanceolate, abruptly contracted into shorter winged petioles: fls. violet or blue. For *C. appenninum*, Linn., see *Solenanthus*. A new plant, *C. furcátum*, Wall., has recently been

1190. Bur of Hound's tongue or stick-tight. (×1½)

1189. *Cynodon dactylon*. (Natural size.)

intro. It is a hairy herb, 1–3 ft. high, with large lvs. and numerous blue fls. in clusters as in forget-me-not. India. Fls. in June. See page 3567.

*C. amabile*, Stapf & Drummond. Allied to *C. furcatum*, but has larger fls. Perennial. S.W. China. N. TAYLOR.†

**CYNÓRCHIS** (Greek for *dog orchid*). *Orchidaceæ*. Terrestrial orchids, grown in the warmhouse.

Flower-clusters loose; sepals and petals similar, or the petals smaller, spreading; lip spreading, 3–5-lobed, spurred; anther short, with 2 points, between which arises the middle lobe of the beak.—About 25 species, of the Mascarene Islands and tropical Africa.

The following have been in cult.: *C. compacta*, Reichb. f. Fls. white, the disk of lip red-spotted. Natal. B.M. 8053. O.R. 19:265. —*C. Loviana*, Reichb. f. Lateral sepals light green, the lip bright rose-purple, the spur clavate. Madagascar. B.M. 7551. (as *C. purpurascens*). O.R. 19:273. G. C. III. 43:184. —*C. Morlandii*, Rolfe. Racemes 5–9-fld.; fls. medium-sized, lilac. Mozambique. —*C. purpurascens*, Thomas. Fls. numerous in a spike-like raceme or head, rose, with the disk of the lip white. Mascarene Isls. B.M. 7852. O.R. 14:305; 15:121; 19:272. G. C. III. 29:87; 35:227. —*C. villosa*, Rolfe. Raceme spike-like, densely fld.; fls. rose-purple, the sepals glandular-hairy. Madagascar. B.M. 7845.

GEORGE V. NASH.

**CYNOSÛRUS** (Greek *kuon*, a dog, and *oura*, a tail). *Gramineæ*. Dog's-TAIL-GRASS. Cespitose grasses with flat blades and spike-like panicles, two species of which are cultivated as ornamental grasses and in lawns and pastures.

Spikelets of 2 forms in small fascicles, the terminal spikelets perfect, the lower sterile, consisting of several empty glumes.—Species about 6, in the north temperate regions of the Old World.

*cristatus*, Linn. CRESTED DOG'S-TAIL. Fig. 1191. Perennial, 1–2 ft.: spike 1–3 in. long; awns shorter than the lemmas. Eu. Dept. Agric., Div. Agrost. 20:146. —Sometimes used in mixtures of lawn or pasture grasses.

*élégans*, Desf. Annual, 6–18 in.: panicle loose, 1-sided, about 1 in. long; awns silky, longer than the lemmas, sometimes as much as 1 in. Eu.—Used for dry bouquets.

A. S. HITCHCOCK.

**CYNTHIA**: Krigia.

**CYPÉLLA** (application obscure). *Iridaceæ*. South American bulbs, resembling Iris.

Half-hardy: bulb tunicate; lvs. radical or cauline; fls. 1–3 from a spathe, yellow, orange or blue; segms. free, narrow or broadly unguiculate, the outer ones spreading and the inner erect and somewhat recurved at the apex. The genus differs from Iris and Moræa in its stigmas, which are neither petal-like nor filiform, but erect, and in the anthers, which are broad, erect, not curved, bearing the pollen on their edges, also in the plaited lvs. Perhaps a half-dozen species.—The bulbs should be set out in spring, lifted in fall and stored over winter. Prop. by offsets or by seed, which should be sown as soon as ripe. The blue-fld. species are presumably equally worthy of cult. For the still showier *C. cerulea*, see *Marica*.

A. *Style appendages spur-like*.

**Hérbertii**, Herb. Lvs. about 1 ft. long, linear, acuminate, twice plaited, the angles of the plaits winged: scape 2–3 ft. high, erect, flexuose, glaucous, branched, many-fld.; fls. 3 in. across, chiefly yellow, odorless, soon withering; outer segms. bearing a rather long cusp or

tail. S. Brazil. Uruguay. Argentina. B.R. 949 (as Moræa) and B.M. 2599 (as Tigridia) show very distinct colors, but Baker says there is a lilac variety.

**plúmbea**, Lindl. Three to 4 ft., the st. glaucous, round and thickish; lvs. not very close together, sheathing at the base, plicate and glaucous: fls. fleeting, at their best early in the morning, not unlike those of *Iris versicolor*, and the same color; style slender, broadening at the apex into a spur-like appendage. Trop. S. Amer.—Has been offered under the name *C. platensis*, which is otherwise unknown in botanical and horticultural literature.

AA. *Style appendages petal-like, flat*.

**peruviána**, Baker. Lvs. 6–9 in. long, linear, narrowed gradually from the middle both ways, glabrous, plaited: fls. 2–3 in a solitary stalked cluster, soon withering, chiefly yellow; segms. with a distinct long claw and a proportionately shorter and broader blade and a shorter cusp, at the base spotted brown. Peru. B.M. 6213.

N. TAYLOR.†

**CYPERÓRCHIS** (*Cyperus* and *Orchis*, from the sedge-like appearance). *Orchidaceæ*. Epiphytic orchids, thriving in the warmhouse.

Very closely allied to *Cymbidium*, from which it differs in the narrower sepals and petals which are connivent to the middle or beyond, thus preventing the full expansion of the fl., and by the straight narrow lip.—There are 3 species, natives of the Himalayas and the Khasia Hills.

*élégans*, Blume. Fig. 1192. Pseudobulbs short, 2–3 in. long; lvs. linear, up to 20 in. long, streaked, pale yellow-green: raceme many-fld., dense, pendulous; fls. yellow, 1½–2 in. across; sepals and petals linear-oblong, the recurved tips acute; lip cuneate, 3-lobed, the middle lobe oblong, short, obtuse; disk with 2 raised orange lines. Himalayas. B.M. 7007.

**Mástersii**, Benth. (*Cymbidium Mástersii*, Griff.). Pseudobulbs 4–10 in. long; lvs. up to 2½ ft. long, acute: racemes 6–10-fld.; fls. about 2 in. across, almond-scented, ivory-white; sepals and petals oblong-linear; lip usually spotted rose-purple, the lateral lobes roundish-oblong, the middle lobe undulate, reflexed, oval;

1192. *Cyperorchis elegans*.  
(× ⅓)

disk with 2 raised orange lines. Sikkim and Khasia Hills. B.R. 31:50. F.M. 1879:346; 1880:391. Lind. 5:222. J.F. 3:289. O. 1910:8.

GEORGE V. NASH.

**CYPÉRUS** (ancient Greek name). *Cyperaceæ*. A large genus of the sedge family, inhabiting both tropical and temperate regions. The species in cult. are all perennials from rootstocks or tubers: lvs. grass-like: st. simple and mostly naked above: fls. perfect, without

perianth, borne in small, compressed spikes, which are variously aggregated in compound umbels, the latter surrounded by foliaceous bracts; styles and stamens 3.—A few are cult. in jardinières, aquatic gardens and aquaria. Several others are pests in cult. fields. P. 3567.

## INDEX.

<i>alternifolius</i> , 3.	<i>fertilis</i> , 5.	<i>natalensis</i> , 4.
<i>compressus</i> , 7.	<i>flabelliformis</i> , 2.	<i>Papyrus</i> , 1.
<i>conglomeratus</i> , 8.	<i>gracilis</i> , 3.	<i>pungens</i> , 8.
<i>diffusus</i> , 6.	<i>laxus</i> , 6.	<i>rotundus</i> , 11.
<i>elegans</i> , 6.	<i>longus</i> , 10.	<i>strigosus</i> , 13.
<i>esculentus</i> , 12.	<i>lucidus</i> , 9.	<i>variegatus</i> , 3.

## A. Basal lvs. much reduced or wanting.

## B. Umbel-rays nearly 100, much longer than the 3–10 involucre lvs.

1. *Papyrus*, Linn. (*Papyrus Antiquorum*, Willd.). EGYPTIAN PAPER PLANT. PAPHYRUS. Cespitose, strict, tall and stout, 4–8 ft. high: st. obtusely 3-angled, smooth: involucre lvs. only 3–10, small, 3–6 in. long, 3–12 lines wide, lanceolate, acute: primary rays of the umbel very numerous, slender, furrowed, equal and drooping, 10–20 in. long; secondary bracts prominent, filiform, 1–6 in. long; spikelets clustered and sessile, pale chestnut; scales obtuse, rachis strongly winged. Egypt, Palestine. Gn. 30, p. 348; 57, p. 105. G.M. 40:799. G.W. 2, p. 571.—For aquaria and damp soil. Not hardy N.

## BB. Umbel-rays 25 or less.

## C. Involucre lvs. very numerous, somewhat separated, much exceeding the umbel; rachis scarcely winged.

## D. Scales broadly ovate: lvs. scabrous throughout.

2. *flabelliformis*, Rottb. Rhizome horizontal, stoloniferous, stout: st. stout, spongy at base, 2–4 ft. high, obtusely angled: involucre lvs. 15–25, 2–8 lines wide, 6–16 in. long, strongly nerved or plicate: umbel lax, about a third as long as involucre; spikelets very numerous, elliptic-oblong, very flat, lustrous, 1½–3½ lines long; scales firm, lustrous, scarcely striate, carinate, barely acute, closely imbricated, pale brown with dark brown area on each side. Afr.—Rare in American trade. Tall and palm-like; used by the natives for wickerwork; very ornamental in water-gardens.

## DD. Scales lanceolate: lvs. scabrous only at apex.

3. *alternifolius*, Linn. UMBRELLA PLANT. UMBRELLA PALM. Fig. 1193. Cespitose, strict, 1–4 ft. high: st. nearly terete, ribbed, smooth and slender: involucre lvs. about 20, spreading or slightly drooping, linear, 4–8 in. long, 2–5 lines wide, plain: umbel open; rays only 1–3 in. long; spikelets numerous, ovate-lanceolate acute, very flat, 2 lines long, pale brown suffused with darker brown, dull; scales thin, very acute, somewhat nerved. Madagascar.—Much used for aquaria and jardinières. Gn. 35, p. 573. A.G. 17:57. V. 4: 159; 5:39. Var. *variegatus*, Hort. St. and lvs. striated with white, sometimes entirely white. Var. *gracilis*, Hort. Plant smaller and more slender: involucre lvs. much narrower and shorter, and not so spreading.—The above description is from Boeckeler, and from a specimen from Madagascar. The plant in cult. under the name *C. alternifolius* may not be that species. The lvs. are too long, too scabrous and too veiny; and the spikelets are elliptic-oval, or oval, 2 lines long, and have broader and more closely overlapping scales than in the typical form. The illustrations cited are probably of the garden plant.

## CC. Involucre lvs. about 3, contiguous, shorter than umbel; rachis strongly winged.

4. *natalensis*, Hochst. Rhizome long, stout and hard, 2 lines thick, scaly: st. solitary, 2–3 ft. high, the size of a goose-quill, triangular: lvs. 2–6 in. long, often wanting; involucre lvs. 3, only 1–3 in. long: umbel rather dense; spikelets 5–9 (rarely 12) lines long, linear-

lanceolate, scarcely compressed, rigid; scales obtuse, not carinate, nerved, shining, pale or brownish. Natal.—Decorative. Not hardy.

## AA. Basal lvs. well developed.

## B. Sts. very short, 3–5 in. high: umbel-rays up to 2 ft. long, weak, decumbent.

5. *fertilis*, Boeck. Roots fibrous: lvs. numerous, about equaling the st., 3–7 lines broad, margins strongly scabrous; involucre lvs. 6–7, short: rays flaccid, pendulous, often rooting at apex; spikelets few, ochraceous or olive, oblong or oblong-lanceolate, obtuse, slightly compressed, 8–10-fl., 3–4 lines long; scales obtuse, nerved. W. Afr. G.W. 8, p. 523.—Recently intro., and excellent for hanging-baskets. The umbel-rays often bear plantlets instead of spikelets.

1193. *Cyperus alternifolius* or umbrella plant.

## BB. Sts. longer than the umbel-rays.

## C. Rachis of spikelet wingless: scales broad, much overlapping, acute or mucronate: spikelets lanceolate or lance-oblong.

## D. Involucre bracts 2–6 lines broad, about 6–12 in number.

6. *diffusus*, Vahl (*C. elegans*, Hort. *C. laxus*, Hort.). Roots fibrous: st. solitary, 1–3 ft. high: basal lvs. many, equaling the st., 2–7 lines broad; margin scabrous; involucre lvs. 4–15 in. long, 2–6 lines broad, longer than the infl.: umbel diffuse; spikelets greenish yellow or pale brown, linear oblong or ovate-lanceolate, 3–8 lines long; scales loose, soft, dull; midrib deeply striate, cuspidate. Tropics. G.C. II. 1874:99; III. 13: 41.—For table decoration. As now interpreted, *C. elegans*, Linn., is a more rigid plant with narrower lvs.

## DD. Involucre bracts 1½ lines broad, or less, 3–6 in number.

## E. Lvs. flaccid: infl. usually open; spikelets very flat; scales 1½ lines long.

7. *compressus*, Linn. Roots fibrous: st. cespitose, 2–16 in. high: lvs. 2–3, slightly shorter than the st., scabrous only near apex: umbel of several pedunculate, sessile heads, or reduced to 1 sessile head; spikelets lance-oblong or lance-linear, 4–12 lines long; scales soft, carinate, acuminate, striate close. Tropics.—Cult. in Eu.

EE. *Lvs. rigid: infl. congested; spikelets thicker; scales*  
 $2\frac{1}{2}$  lines long.

8. *pungens*, Boeck. Roots of coarse lanate fibers: st. 6–20 in. high, stiff, terete above: lvs. several, with conspicuous, loose, brownish sheaths, equaling the st.

1194. *Cyperus esculentus*.—Chufa.

or shorter, narrow,  $\frac{1}{2}$  to  $\frac{3}{4}$  lines broad, thick and rigid: umbel congested, often simple; spikelets 5–9 lines long, lanceolate or ovate-lanceolate, pale brown; scales firm, with thin margins, obscurely carinate, inconspicuously striate, apiculate; midrib obscure, close. N. Afr. and S. W. Asia.—By some authors united with *C. conglomeratus*, Rottb., under the latter name. There is some reason to suspect that the plant in the trade under this name may not be this species.

CC. *Rachis of spikelet with scarious, winged margin; scales obtuse or obtusish, less overlapping; spikelets linear.*

D. *Lvs. thick, glossy.*

9. *lucidus*, R. Br. Rhizomes short and thick: sts. stout, 2–3 ft. or even 4 ft. high, sharply 3-angled: lvs. equaling the st. or longer, 3–6 lines wide, margins scabrous; involucrel lvs. 3–6, the lower very broad, often  $1\frac{1}{2}$ –3 ft. long: umbel large, lax, compound; rays many, 9 in. long or less; spikelets spicate, rich deep brown, lustrous, linear, flattish, acute, 4–6 (rarely 7–8) lines long; wings of rachis narrow; scales loosely imbricated, few-nerved, 2 lines long. Austral.

DD. *Lvs. thinner, duller.*

E. *Rootstock long, stout, 2–2½ lines thick.*

10. *longus*, Linn. Sts. 2–4 ft. high, acutely angled, stoutish: lvs. several, with long sheaths, about equaling the culm 2–4 lines wide; margins finely scabrous; involucrel bracts very long, often 8–24 in.: umbel lax, the rays 12 in. or less long; spikelets 3–15 lines long, linear, dull, dark chestnut-brown, rarely paler, slightly compressed; scales  $1\frac{1}{4}$ – $1\frac{1}{2}$  lines long, scarcely carinate, obscurely striate; midrib green. Eu.—Cult. in Eu.

EE. *Rootstock long, slender, tuber-bearing.*

F. *Scales dark reddish brown.*

11. *rotundus*, Linn. NUT-GRASS. COCO-GRASS. Rootstocks  $\frac{1}{4}$  line thick: sts. 4–24 in. high, bulbous, thickened at the base, rather slender, 3-angled: lvs. several, usually shorter than the st., only 1–2 (rarely 3) lines wide; margins finely scabrous; involucrel bracts 2–4, scarcely longer than the infl.: umbel lax; rays few, 4 in. long or less; spikelets linear, 5–12 lines long, inconspicuously spicate on the branches, few in a cluster, dull; scales  $1\frac{1}{4}$  lines long, scarcely striate, obscurely carinate; midrib green: achenes linear, acute. Tropics and subtropics.—A weed southward.

FF. *Scales brownish chestnut or stramineous.*

12. *esculentus*, Linn. CHUFA. Fig. 1194; also Fig. 959. St. 8 in. to 3 ft. high, stoutish: lvs. several, equaling the st. or slightly shorter, rarely longer, 2–4 lines wide; involucrel lvs. exceeding the infl.: umbel open; rays  $\frac{1}{2}$ –4 in. long; spikelets very numerous, spicate on the branches, crowded, divaricate, brownish stramineous, linear, 4–12 lines long, scarcely compressed; scales lax, several-nerved, dull, rarely carinate; midrib somewhat green: achenes oblong, obtuse. Tropics and subtropics.—A weed in sandy cult. fields northward and southward; rarely grown for the edible tubers.

EEE. *Rootstock globular; spikelets stramineous.*

13. *strigosus*, Linn. Running rootstocks absent, not tuber-bearing: sts. rather stout, 1–3 ft. high, sharply 3-angled; base bulbous: lvs. numerous, usually equaling the st., 2–4 lines wide, more or less scabrous; involucrel bracts 6–12 in. long, usually exceeding the infl.: umbel open, rays several, 6 in. long or less; spikelets very numerous, spicate on the branches, crowded, divaricate, linear-subulate, 5–8 lines long, scarcely compressed; scales  $1\frac{1}{2}$  to 2 lines long, appressed, dull, striate; midrib green. N. Amer.—Hardy perennial, used for the border of aquatic gardens. K. M. WIEGAND.

1195. *Cyphomandra betacea*. ( $\times\frac{1}{2}$ )

**CYPHOKENTIA** (allied to *Kentia*, differing, among other things, in having a lateral protuberance or tumor on the fr., whence the name). *Palmaceæ*. Feather-lvd. robust spineless palms, of very few species in New Caledonia, suitable for the warmhouse but little grown. The lvs. are terminal and pinnate-parted, the segms. long-sword-shaped and narrowed at apex, the margins at base recurved: spathe-valves 2, deciduous, bearing stout glabrous branching spadices; fls. declinuous, the stamens 6 or 12: fr. small, globose or ellipsoidal. Engler and Prantl combine *Cyphosperma* and *Microkentia* with this genus, comprising, about 10 species, all of New Caledonia. The original species are: *C. robusta*, Brongn., with the branches of the spadix thick and long-cylindrical, fr. reniform-ellipsoidal, stigma not prominent above the base, and seeds reniform; *C. macrostachya*, Brongn., with long flexuose spadix branches, globose fr., lateral stigma, and usually subglobose seeds. The cyphokentias probably require the treatment given arecas.

L. H. B.

**CYPHOMÁNDRA** (from the Greek, referring to the hump-shaped anthers). *Solanaceæ*. South American spineless shrubs or small trees, one of which is sometimes grown for its edible fruit.

The genus is distinguished from *Solanum* chiefly by the thickened connective of the anthers: the plants are erect and usually stout and the large lvs. are entire, 3-lobed, or pinnatisect: fls. pedicellate, in racemes, scorpioid cyme-branches, or arising below the nodes; calyx and corolla 5-lobed, the corolla somewhat rotate, the tube very short; anthers porose or acuminate at apex; ovary 2-celled: fr. an ovoid or oblong fleshy berry, many-seeded.—Some 30 or more species, of little concern to the horticulturist.

**betacea**, Sendt. (*Solanum fragrans*, Hook.). TREE TOMATO. Fig. 1195. Cult. occasionally for the egg-shaped, reddish brown, faintly striped frs., and under such conditions it becomes a tree-shaped, half-woody plant 6-10 ft. high: lvs. large, soft-pubescent, cordate-ovate, more or less acuminate, entire: fls. small, pinkish, fragrant, in small axillary or super-axillary clusters: fr. about 2 in. long, on slender stalks, 2-loculed and seedy, musky-acid and tomato-like in flavor, agreeable to those who like tomatoes. Brazil. B.M. 3684. J.H. III. 31:470. G.C. III. 25:105. A.G. 11:409.—Bears the second and third year from seed, under glass (where it must be grown in the northern states). Grown mostly as a curiosity.

L. H. B.

**CYPHOPHÈNIX** (*hump* and *Phoenix*, a palm). *Palmaceæ*, tribe *Arèceæ*. A rather unimportant genus of unarmed, stout-stemmed palms, with terminal pinnatisect leaves.

Leaflets acute at the apex, sword-shaped, the base often with a thickened and recurved margin; rachis stout and broad, a little convex on the lower side: spadix glabrous, with many long stout branches bearing short bracts and numerous monoecious fls.; sepals thick and leathery, round and a little concave: fr. elongate-ovoid or rarely ellipsoid.—There are only 2 species, both from New Caledonia. They have something the aspect of *Kentia* from which they differ in having only 6 stamens. They are almost unknown in the trade. For cult., see *Kentia* or *Howea*.

**élegans**, Benth. & Hook. (*Kéntia elegans*, Brongn. & Griseb.). Rachis convex below, keeled above; lfts. alternate, not close together, scaly along the mid-nerve below, 3-nerved: spadix more or less spreading or reflexed in age, simply branched: fr. oblong-elliptical, acute.

**fulcita**, Benth. & Hook. (*Kéntia fulcita*, Brongn.). St. clothed at the base with smooth aerial roots: fr. ovoid, attenuate above.—A tall graceful palm scarcely known outside of botanic garden collections.

N. TAYLOR.†

**CYPHOSPÉRMA** (Greek, *hump* and *seed*). *Palmaceæ*, tribe *Arèceæ*. Unarmed stout-stemmed palms with a crown of pinnately divided, terminal leaves.

Leaflets leathery, sword-shaped, the apex narrowly oblique, the base with a thickened recurved margin: rachis broad and stout, slightly convex beneath, channelled above: spadix smooth and much branched, the branches distichous; fls. spirally disposed on the spadix, brownish, otherwise as in *Cyphophœnix*: fr. globose or 4-5-angled.—Two species of New Caledonian palms, rare in cult. in U. S. and only doubtfully in the trade. See *Cyphokentia*; for cult. see *Areca*. The young plants have rather stiff petioles, but graceful, arching lf.-segms. G.C. II. 24:362.

**Vieillardii**, Benth. & Hook. (*Cyphokéntia Vieillardii*, Brongn.). St. medium height: lvs. pinnatisect, the lfts. thick and narrowly sword-shaped: fr. obtuse, 4-5-angled, the seed also acutely angled.—A rare palm, known also under the names *Kentia robusta* and *K. Vieillardii*.

N. TAYLOR.

**CYPRESS**: *Chamæcyparis*, *Cupressus* and *Taxodium*.

**CYPRESS VINE**: *Ipomœa*.

**CYPRIPEDIUM** (*Venus'-slipper*). LADY'S SLIPPER. MOCCASIN-FLOWER. *Orchidaceæ*. Attractive hardy orchids, often planted in moist cool borders, bogs, and sometimes in rock-gardens.

Stems very short, with a pair of lvs. close to or near the ground, or long and leafy: lvs. commonly many-nerved: fls. terminal, 1 to few, withering on the ovary; lateral sepals free, or united nearly or to the apex, the dorsal sepal erect; petals generally narrower, spreading; lip saccate, rarely split down the front; ovary 1-celled, with 3 parietal placentæ.—Species about 30, in the north temperate zone. For the greenhouse species formerly included here, see *Paphiopedilum*, and *Phragmipedium*.

A. Lvs. 2, opposite: lip split in front.

**acaule**, Ait.

Lvs. flat on the ground, ovate to oblong-oval: scape with 1 fl.; upper sepal and petals brownish, lanceolate; labellum pink-purple, darker veined. May, June. Newfoundland to N. C., west to Ind., Mich. and Minn. A.G. 13:514; 14:405. Gng. 4:263. A.F. 11:1049. G.C. III. 46:209.

**japonicum**, Thunb. Lvs. above the ground roundish, undulately plicate; bract longer than the ovary; fl. terminating the scape; sepals and petals lanceolate, acuminate, greenish, dotted with red; labellum white-pink. April, May. Japan. G.C. III. 33:355.

AA. Lvs. several, alternate: lip not split.

B. Lateral sepals free.

**arietinum**, R. Br. Plant about 6 in. high, slender: lvs. lanceolate: fls. small, resembling a ram's head, terminal, solitary; upper sepal ovate-lanceolate, brownish green; petals linear; labellum tapering at the apex, white veined with reddish purple, clothed with white, woolly hairs near the aperture. May. Maine to N. Y., Mich. and Minn., and northward. B. M. 1569. L.B.C. 13:1240. F.S. 20:2095.

BB. Lateral sepals united nearly or to the apex.

c. Fls. yellow.

**pubescens**, Willd. Fig. 1196. Lvs. oval, acute: petals usually twisted, much narrower than the ovate-lanceolate sepals;

labellum pale yellow; staminodium triangular. Same range as the next. May, June. B.M. 911 (as *C. parviflorum*). A.G. 13:513. Mn. 7, p. 5. G.C. III. 33:379; 47:369.—The rhizomes and rootlets are employed in medicine for their antispasmodic and nervine properties. Perhaps a form of the next.

**parviflorum**, Salisb. Lvs. ovate, acute: fls. smaller than in *C. pubescens*; labellum flattened from above and below, not laterally, bright yellow; staminodium triangular. May, June. Newfoundland to Ga., west to Minn. and E. Kans. A.G. 13:515. G.C. III. 46:227.—Same medicinal uses as *C. pubescens*.

cc. Fls. white or greenish.

d. Number of fls. 1-3.

**candidum**, Muhl. Lvs. oblong-lanceolate: fls. terminal, solitary; sepals broader than the petals, ovate-lanceolate; petals spreading like the sepals, greenish; labellum white, striped inside with purple; staminodium lanceolate. May, June. N. Y., Pa., Minn., Mo. and Ky.

**reginae**, Walt. Fig. 1197. Plants stout: lvs. oval, acute: sepals ovate, rather roundish, white; petals oblong, white; labellum white or pale pink-purple; staminodium oval-cordate. June. Maine, W. New England to Minn. and Mo., Mts. of N. C. R.H. 1868: 410. Gn. 53, p. 77; 61, p. 191; 65, p. 447. R.B. 20, p. 198. A.F. 11:1048. Gng. 4:262, 327. G.C. III. 29:21; 47:370; 50:315. Known also as *C. hirsutum* and *C. spectabile*.

**montanum**, Douglas. One to 2 ft., leafy, pubescent: lvs. ovate to broad-lanceolate, 4-6 in. long: fls. 1-3, short-pedicelled, the wavy-twisted petals brownish, the inch-long lip dull white veined with purple: caps. erect or nearly so. Calif. to Wash. B.M. 7319.—Fragrant. Grows in clumps. Handsome.

dd. Number of fls. 6-12.

**californicum**, Gray. Fig. 1198. Plants either slender or stout, varying in height, sometimes exceeding 2 ft.: lvs. ovate-alternate: floral bracts very large, becoming narrowly ovate: fls. small, from 6-12 open at the same time, an inch or more apart on the st.; labellum whitish; sepals oval, yellowish green; petals narrowly oblong, colored like the sepals. Calif. B.M. 7188. G.F. 1:281 (adapted in Fig. 1198). G.C. III. 41:418; 46:211.

*C. Calceolus*, Linn. Fls. single: sepals and petals deep brown; lip yellow, slightly compressed. Eu. R.H. 1892, p. 392. R.B. 21, 210. G.C. III. 46:210.—*C. debile*, Reichb. f. Lvs. 2, opposite: fls. small, the sepals and petals pale green with a dark brown basal blotch, sometimes brown-striped, the lateral sepals united; lip white, brown-streaked about the mouth. China and Japan. B.M. 8183.—*C. elegans*, Reichb. f. Sts. 4 in. tall: lvs. opposite: fl. single, the sepals and petals brown-veined, the lateral sepals united; lip brownish, corrugated. Tibet.—*C. guttatum*, Swartz. Lvs. 2, alternate: fls. single, white, blotched with purple. N.E. Eu. to N.W. Amer. B.M. 7746.—*C. himalaicum*, Rolfe. Sts. up to a foot tall: lvs. 3: sepals and petals brownish, deeper veined; lip brown-purple, many-nerved. Bhotan.—*C. trapezium*, Llav. & Lex. Lvs. ovate-lanceolate: fls. several, large, pale yellow, the large lip with some scarlet spots about the mouth. Mex.—*C. macranthon*, Swartz. Fls. purple, the lip contracted at the mouth. Siberia and N. Asia. R.H. 1877:310. B.M. 2938. G.C. III. 46:212.—*C. speciosum*, Rolfe. St. leafy: fls. whitish or flesh-colored, veined with rose; lip subglobose. Japan. B.M. 8386.—*C. Thunbergii*, Blume. Fls. pale purple. G.C. III. 46:228.—*C. tibeticum*, King. Fls. 3-4 in. across: sepals and petals white, light yellow at apex, veined with maroon-purple; lip maroon-purple. E. Tibet and W. China. B.M. 8070. G.C. III. 39:347; 46:420; 49:403, 410.—*C. ventricosum*, Hort. Said to be a natural hybrid between *C. Calceolus* and *C. macranthon*. G.C. III. 46:229.

GEORGE V. NASH.

**CYRILLA** (after Dominico Cyrillo, professor of medicine at Naples, 1734-1799). *Cyrollaceae*. Woody or nearly tree-like, rarely cultivated for its handsome bright green foliage and white flowers in slender racemes.

Leaves alternate, without stipules, short-petioled, entire, glabrous, deciduous or nearly persistent: fls. small, white, in narrow slender racemes, 5-merous; stamens 5-10; ovary superior with 2 short styles: fr. a small indehiscent 2-celled caps. with 2 seeds.—Probably one variable species from N. C. to Fla. west to Texas, and in W. India and S. Amer. Plant with handsome bright green foliage, and graceful racemes of white fls., hardy north to N. Y. Thrives best in humid sandy soil and shady position. Prop. by seeds and cuttings under glass, with slight bottom heat.

**racemiflora**, Linn.

**LEATHERWOOD.**

Shrub, occasionally tree to 30 ft.: lvs. cuneate, oblong or oblanceolate, usually obtuse, reticulate-veined, 2-3 in. long, bright green, turning orange and scarlet in fall, but in tropical climates evergreen: racemes 4-6 in. long, erect, at length nodding. B.M. 2456. S.S. 2:51. G.C. III. 30:198. J.H. III. 43:197.—The variety from W. Indies has been described as *C. antillana*, Michx., that of Brazil as *C. racemifera*, Vandelli, and a small-lvd. form from Fla. and La. as *C. parvifolia*, Raf.

ALFRED REHDER.

1198. *Cypridium californicum*. ( $\times \frac{1}{2}$ )

1197. *Cypridium spectabile*. ( $\times \frac{1}{2}$ )

**CYRTÁNDRA** (name refers to the curved stamens). *Gesneriaceæ*. A large group of tropical shrubs and trees, two or three of which are more or less known in cult. for their fls.; akin to *Trichosporum* (*Æschynanthus*); warmhouse subjects. Lvs. opposite, or alternate by failure of one of the pair, membranaceous, or fleshy or leathery: fls. usually white or yellowish, in fascicles, heads or cymes; corolla-tube cylindrical, the limb more or less 2-lipped; perfect stamens 2, and 2 or 3 small staminodia. Nearly 200 species in the islands of the Indian and Pacific oceans and in China. *C. pendula*, Blume. Short and stout: lvs. long-petioled, elliptic or lance-elliptic, acute, gray-blotched above: fls. white with brown calyx,  $1\frac{1}{2}$  in. long, the corolla inflated, and purple-dotted on lower side. Java. *C. Pritchardii*, Seem. Lvs. petioled, elliptic, obtusely toothed, acute: fls. small, white, in 3-fl. cymes. Fiji Isls.

**CYRTANTHÈRA**: *Jacobinia*.

L. H. B.

**CYRTÁNTHUS** (Greek, *curved flowers*; from their pendulous habit). *Amaryllidaceæ*. Tender bulbs from South Africa, known only in a few American greenhouses.

Flowers umbellate, pendulous or erect, usually red or white with green stripes; stamens inserted in the tube of the corolla; ovary 3-celled, crowded with numerous ovules, the seeds flat.—Species 20. Their cult. is like that of *hemanthus* and many other bulbs from the same region. They are suitable for pot culture, or for planting out in summer. The following analytical key gives an idea of the group, and its 3 subgenera.

A. Fls. many in an umbel, pendulous.

B. Lvs. strap-shaped. (*Cyrtanthus proper*.)

**obliquus**, Ait. Bulb ovoid, 3–4 in. thick: lvs. 10–12, strap-shaped, distichous, produced after the fls.,  $1\frac{1}{2}$ –2 ft. long: scape 1–2 ft. long, stout, mottled; fls. 10–12 in an umbel, entirely drooping, odorless, bright red, with more or less yellow, and greenish tips 2–3 in. long; pedicels  $\frac{1}{2}$ –1 in. long; style not exserted. Cape Colony. B. M. 1133. L.B.C. 10:947.

BB. Lvs. linear. (*Monella*.)

**Máckenii**, Hook. f. Bulb  $1\frac{1}{2}$  in. thick: lvs. 2–6, appearing with the fls., linear, 1 ft. long: scape slender, slightly glaucous; fls. 4–10 in an umbel, pure white, 2 in. long; style exserted. Natal. G.C. 1869:641. Gn. 50, p. 63.

AA. Fls. single, or few in an umbel, erect or slightly curved downward. (*Gastronema*.)

**sanguineus**, Hook. Bulb 2 in. thick: lvs. 3–4, appearing with the fls., lanceolate, petioled, 1 ft. long: scape slender, 6–9 in. long; fls. 1–3, bright red, 3–4½ in. long, wider funnel-shaped than in the 2 preceding species, with a throat 1 in. across. Caffraria, Natal. B.M. 5218. Var. **glaucophyllus**, Hort. A form with somewhat glaucous foliage and orange-red fls.

*C. Huttonii*, Baker, belongs to *Cyrtanthus proper*, but its lvs. appear with the fls., and it has 6–8 or even 12 pale red fls. about 1 in. long and a much shorter style than in *C. obliquus*. Cape Col ny. B.M. 7488. Gn. 50:62.—*C. inaequalis*, O'Brien. Fls. erect, coral-red, borne in umbels on scapes 1 ft. high; upper segms. of perianth overhanging. Cape Colony. G.C. III. 37:261.—*C. Jimodii*, Beauverd. Umbel 6–9-fl.; fls. cinnabar, yellow at apex, pendulous. Transvaal.

N. TAYLOR.†

**CYRTOCÁRPA** (Greek, *curved fruit*). *TAPIRA*. *Anacardiaceæ*. One or two Mexican trees, one of which bears a small fruit, likened to a cherry by the natives of Lower Calif.

Leaves alternate, compound: fls. axillary or terminal, paniculate, polygamous: fr. an oblique drupe, 1-seeded. Intro. into S. Calif. by Franceschi. Sometimes united with *Tapiria* (or *Tapirira*), from which it differs in its straight embryo and other characters.

**procèra**, HBK. Very tall tree, with slender, terete, dark purplish, resinous branches: lvs. alternate, odd-pinnate; lfts. 5–7 or 9, oblong, entire, with a very slight silkiness, especially below, very shortly stalked, 1 in. or more long, half as wide: fls. white, inconspicuous, in panicles 1–2 in. long; calyx 5-parted, villous, persistent; segms. roundish; petals 5, elliptic; stamens 10; style 1: fr. the size of an olive, edible. Mex. HBK. 6, t. 609.

**CYRTOCÈRAS**: *Hoya*.

**CYRTOCHÏLUM**: *Oncidium*.

**CYRTODÈIRA**: *Episcia*.

**CYRTÔMIUM** (Greek, *a bow*). *Polypodiaceæ*. Asiatic half-hardy or greenhouse ferns of rigid habit.

Leaves simply pinnate, anastomosing veins and firm indusia fixed by the depressed center. It differs from *Polystichum* mainly in venation.—Three or four species known.

Culture as for *Polystichum*, to which it is closely allied.

A. Margins of pinnae entire or slightly undulate.

**falcatum**, J. Smith. Fig. 1199. HOLLY FERN. Pinnae glossy, ovate, falcate; the lower rounded or

obliquely truncate at the base, 4–6 in. long, 1–2 in. wide. Japan, India.—The large thick glossy foliage makes it an excellent fern for decorations. One of the species used in fern-dishes and one of the few species which can be made to thrive under ordinary house conditions. Plants from the temperate parts of Japan will do well out-

1199. *Cyrtomium falcatum*. (Leaf  $\times \frac{1}{4}$ )

of-doors in the northeastern states if given slight winter protection. For another illustration, see article on ferns. *C. Bütterfeldii*, Hort., is a form of this species differing in having the pinnae deeply serrate. *C. Rochfordianum*, Hort., recently advertised, is a variety of *C. falcatum* with fimbriated lfts. Superficially these two forms resemble *C. caryotideum* somewhat, but the species are entirely distinct. It has begun to replace the original form in the dealers' stocks.

**Fórtunei**, J. Smith. Pinnae dull, lanceolate, opaque, 2–4 in. long,  $\frac{1}{2}$ –1 in. wide. Japan.

AA. Margins of pinnae toothed or sometimes lobed.

**caryotideum**, J. Smith. Pinnae larger, 5–7 in. long,  $1\frac{1}{2}$ –2½ in. wide, often auricled on both sides at the base, sharply toothed. India. R. C. BENEDICT.†

**CYRTOPÈRA**: *Eulophia*.

**CYRTOPÒDIUM** (Greek for *curved foot*, from shape of lip). *Orchidaceæ*. Epiphytes, grown in warmhouses. Stems fusiform, bearing plicate lvs.: scapes radical, bearing numerous fls., pure yellow or spotted with crimson; sepals and petals equal, free; column semi-

terete; pollinia 2, caudicle short; gland ovate.—Species 3 or 4 in the tropics. They are large-growing plants, with large and showy fls. They need a rich, fibrous soil with manure. Grow in a warm or tropical house.

**Andersonii**, R. Br. Sts. 5 ft. high: lvs. long, lanceolate, sheathing at the base: scape often 3 ft. high, branching, bearing many yellow fls.; sepals and petals broad, bright yellow, the labellum brighter, front lobe slightly concave. Specimens with over 100 fls. have been recorded. Trop. Amer. B.M. 1800.

**punctatum**, Lindl. Habit as above: scape from 2–3 ft. high, branching about midway, dotted with dull purple, the branches subtended by membranaceous sheathing bracts, which are lanceolate, undulating, and dotted with crimson; sepals oblong-lanceolate, undulate, greenish yellow blotched with crimson; petals similar, spotted at the base; labellum  $\frac{1}{2}$  in. long, fleshy, bright yellow, lateral lobes crimson, midlobe spotted and margined with crimson; column green. Extensively distributed through S. Amer. B.M. 3507. F.S. 22:2352. R.B. 30:158. Var. **Saintlegerianum**, Hort. (*C. Saintlegerianum*, Reich. f.). Has brighter markings on the bracts and fls. J.H. III. 50:91.

1200. *Cystopteris fragilis*. ( $\times \frac{1}{2}$ )

many-fl. fls. about 1 in. across, lemon-colored, spotted rose-pink. Brazil. B.M. 7807.

*C. palmifrons*, Reichb. f. & Warm. Sts. about 2 ft. tall, clothed with the lemon-yellow, purple-margined sheaths: lvs. 6–8 in. long; panicle 12–15 in. long, purple-colored, spotted rose-pink.

OAKES AMES.

GEORGE V. NASH.†

**CYRTOSPÉRMA** (Greek, *curved seed*). *Aracææ*. A handsome warmhouse tuberous foliage plant, with large, hastate red-veined leaves resembling an alocasia, but easily distinguished by its spiny stems.

Herbs with tubers or long rhizomes: lf.- and fl.-stalks often spiny or warty: lvs. hastate or sagittate; petioles long, sheathing at the base.—*Cyrtosperma* has 10–12 species, remarkably scattered in the tropics. Cult. presumably same as alocasia.

**Johnstonii**, N. E. Br. (*Alocasia Johnstonii*, Hort.). Tuberous: petiole 2–2 $\frac{3}{4}$  ft. long, olive-green, spotted rose, covered with fleshy, spine-like warts: lvs. sagittate, depressed in the middle, 1 $\frac{1}{2}$ –2 ft. long, olive-green, with prominent and beautiful red veins above. I.H. 27:395. G.W. 15, p. 340.—Intro. from the Solomon Isls. as *Alocasia Johnstonii*, but when it flowered it became evident that the plant is a *Cyrtosperma*.

*C. ferox*, Lind. & N. E. Br., is a second species of this genus, figured in I. H. 39:153, but not known to be in the American trade. It has narrow-sagittate lvs. on slender, very prickly petioles: spathe rather large, reflexed, greenish white. Borneo.

GEORGE V. NASH.†

**CYRTÓSTACHYS** (Greek for a *curved spike*). *Palmææ*, tribe *Aracææ*. Three or four palms of the Malayan region of stately habit, but little known in this country.

Stem spineless, slender and tall, crowned by a graceful cluster of pinnately divided lvs.: lfts. narrowly lanceolate, a little oblique, at the apex somewhat bifid: spadix short-peduncled, the branches more or less compressed, alternate, sometimes pendulous; fls. monœcious, the two kinds in 1 spadix; stamens 6, rarely 12 or 15: fr. small, elongate-ovoid, tipped by the persistent stigma. For cult., see *Areca*. The small and young lvs. of *C. Renda* are effective but old plants are not very attractive and scarcely known. G.C. II. 24:362.

**Rénda**, Blume. Height 25–30 ft.: lfts. linear or ensiform, obtuse but somewhat obliquely bifid, delicate gray beneath, the petioles dark, brownish red: spadix 3–4 ft. long, the branches nearly alternate, about 18 in. long. Sumatra. Var. **Duvivierianum**, Pynart. Lf.-stalks brightly colored. Malay Archipelago.

**Lákka**, Becc. Petioles green, not over 4 in. long: lvs. broad, boldly arched, 3 $\frac{1}{2}$ –4 $\frac{1}{2}$  ft. long, the lfts. nearly 18 in. long, 1 $\frac{1}{2}$  in. wide, obliquely bifid at the apex, pale beneath. Borneo.

N. TAYLOR.

**CYSTACÁNTHUS** (Greek for *bladder Acanthus*, because the flowers are inflated). *Acanthææ*. Evergreen herbs of Burma and Cochinchina, with showy, sessile fls. in the axils of bracts, the entire infl. more or less crowded into a terminal panicle or thyrs. Corolla-limb spreading, unequally 5-lobed, the lobes short-rotund; stamens 2; style filiform, the stigma 2-toothed: lvs. entire: caps. long and narrow, almost 4-sided, many-seeded. Doubtfully distinct from *Phlogacanthus*.—One species is cult. This is *C. turgida*, Nichols. B.M. 6043 (as *Meninia turgida*). It comes from Cochinchina: 2 ft. or less high, with prominently jointed sts. and opposite, elliptic-lanceolate lvs.: fls. white, yellow in the throat and pink-reticulated on the lobes. April. Cult. as other warmhouse acanthads. (See *Aphelandra* for example.) Prop. by cuttings of young wood. There are 4 or 5 species of *Cystacanthus* in farther India.

**CYSTÓPTERIS** (Greek, *bladder-fern*). *Polypodiææ*. Native ferns, with delicate foliage; deserve to be planted in the hardy fern garden.

Sori round, covered by a delicate indusium which is attached under one side and opens at the other, becoming hood-like in appearance and finally disappearing. The 5 species are native in the north temperate zone. Of easy cult. in shady, rich borders.

**bulbifera**, Bernh. Lvs. 8–24 in long, dark green, 3–5 in. wide, widest at the base, long tapering, tripinnatifid, bearing on the under surface of the rachis a series of bulb-like bodies, which germinate and prop. new plants. Canada to N. C.—Thrives best on lime-bearing rocks. Exceptionally useful and attractive on damp rocky banks.

**fragilis**, Bernh. Fig. 1200. Lvs. clustered, gray-green, 4–8 in. long besides the slender stalks, tripinnatifid, widest above the base. Widely distributed over the world at all altitudes.

L. M. UNDERWOOD.

**CÝTISUS** (Greek name for a kind of clover). *Leguminosææ*. Broom. Woody subjects, chiefly grown for their profusely produced yellow or sometimes white or purple flowers.

Mostly low shrubs, rarely small trees: lvs. trifoliate, sometimes unifoliate, rather small, alternate, deciduous or persistent, sometimes few and minute and branches almost leafless: fls. papilionaceous, axillary or in terminal heads or racemes, yellow, white or purple; stamens 10, connate; style curved: pod flat, dehiscent, with few or many seeds; seeds with a callose appendage at the base.—About 50 species in S. and Cent. Eu., Canary Isls., N. Afr. and W. Asia. For a monograph of the genus see Briquet, *Etude sur les Cytisides des Alpes Maritimes* (1894).

The brooms are ornamental free-flowering shrubs,

blooming most in early spring and summer. Nearly hardy North are *C. hirsutus*, *C. supinus*, *C. scoparius*, *C. nigricans*, *C. leucanthus*, while the evergreen species *C. canariensis*, *C. monspessulanus*, *C. filipes* are hardy only South. Most of the species are well adapted for borders of shrubberies, and thrive in almost any well-drained soil and in sunny position; they naturalize themselves often very quickly in dry, gravelly soil, where few other plants will grow; *C. scoparius* especially does so. The cytisus ought to be transplanted carefully and when young, as they do not bear transplanting well as older plants. Some dwarf species, like *C. Ardoinii*, *C. kewensis*, *C. emeriflorus*, *C. purpureus* and *C. leucanthus* are very handsome for rockeries. The evergreen *C. canariensis* and *C. racemosus* are much grown in the North as greenhouse shrubs, blooming profusely in early spring; also the white *C. multiflorus* and *C. filipes* make handsome pot-plants, and may be had in bloom in February with gentle forcing. For pot-plants, a light sandy loam with peat added forms a suitable compost. After flowering the plants should be cut back and repotted as soon as they start into new growth. After repotting, they are kept close and often syringed until they are established; then they ought to have plenty of air and only slight shade. When the new growth has been finished they may be put in the open air until frost is threatening. During the winter they should be kept in a cool greenhouse with plenty of light and carefully and moderately watered. From January they may be transferred gradually in a warmer house for forcing. Cuttings started in early spring, transplanted several times and then gradually hardened off, can be grown into flowering specimens for the following spring. Propagated by seeds sown in spring and by greenwood cuttings under glass; they are also sometimes increased by layers or by grafting. As stock *C. nigricans* is much used, or *Laburnum vulgare* for small standard trees; for plants grown in the greenhouse or South, *C. canariensis* is a good stock.

Of cytisus, the young growths root readily in December and January in the ordinary way. They should be shifted on as they grow. Good-sized plants can be produced if shifting and pinching is not neglected. By the following winter, the winter-propagated plants should be in 5-inch pots, in which size they are most useful. Keep very cool during winter, and withhold any forcing. They flower in March, or, if kept at a night temperature of 45°, as late as April. Syringe at all times to prevent red spider. To produce good-sized plants in one year, it is best to keep them plunged on a bench under the glass the entire summer, with little shade. Older plants can be plunged out-of-doors during July, August and September. (William Scott.)

grandiflorus, 12.	palmensis, 11.	

A. Calyx tubular, much longer than wide: lvs. always 3-foliolate: branches terete. (*Tubocytisus*.)

B. Fls. in terminal heads with bracts at the base, yellow to white.

1. *supinus*, Linn. (*C. capitatus*, Scop.). Shrub to 3 ft., with erect, or sometimes decumbent, villous branches: lfts. obovate or oblong-obovate, sparingly appressed pubescent above, villous pubescent beneath,

$\frac{3}{4}$ –1 in. long: fls. yellow, brownish when fading, nearly 1 in. long; standard pubescent outside or nearly glabrous: pod villous, 1–1½ in. long. July, Aug. Cent. and S. Eu. L.B.C. 5:497. J.H.III. 31:161 (as *Genista*).

2. *leucanthus*, Waldst. & Kit. (*C. albus*, Hacq.). Upright shrub, to 3 ft., with villous branches: lfts. 3. oblong-obovate, obtuse or acutish, appressed pubescent, sometimes glabrous above, ciliate,  $\frac{1}{8}$ – $\frac{3}{4}$  in. long: fls. 3–6, yellowish white; calyx appressed-villous; standard pubescent outside: pod about 1 in. long, appressed pubescent. June, July. S. E. Eu. Var. *pallidus*, Schrad. (*C. pallidus*, Kerner). Fls. pale yellow. Var. *schipkaensis*, Dipp. Low shrub, about 1 ft. high: fls. white. Bulgaria.—The oldest name for this species is *C. albus*, but as the same combination has been used by many writers for *C. multiflorus*, the name *C. leucanthus* is here used to avoid possible confusion.

BB. Fls. axillary, distributed along the branches.

c. Color of fls. yellow.

3. *hirsutus*, Linn. (*C. elongatus*, Hort., not Waldst. & Kit. *C. polytrichus*, Bieb. *C. ruthenicus*, Hort., not Fisch.). Shrub, to 3 ft., with erect or procumbent, villous, terete branches: lfts. obovate or obovate-oblong, villous pubescent beneath,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long: fls.

1201. *Cytisus canariensis*.  
( $\times \frac{1}{2}$ )

2–3, short-petioled; calyx villous pubescent; standard glabrous on back: pod 1 in. long, villous. May, June. Cent. and S. Eu. Orient. B.M. 6819 (lfts. erroneously shown as serrate). L.B.C. 6:520 (as *C. falcatus*). B.R. 14:1191 (as *C. multiflorus*).

cc. Color of fls. white or purple.

4. *proliferus*, Linn. Shrub, to 12 ft., with long and slender pubescent branches: lfts. oblanceolate, silky pubescent beneath, green and sparsely pubescent above, 1–1¼ in. long: fls. white, 3–8; pedicels rather long, tomentose; calyx tomentose; standard pubescent outside: pod densely tomentose-villous, 1½–2 in. long. May, June. Canary Is. B.R. 2:121. L.B.C. 8:761. G. 32:291.—Recommended as a fodder plant for Calif.

5. *purpureus*, Scop. Procumbent or erect shrub, to 2 ft., quite glabrous: lvs. rather long-petioled; lfts. oval or obovate, dark green above,  $\frac{1}{2}$ –1 in. long: fls. 1–3, purple; calyx reddish: pod black, 1–1½ in. long. May, June. S. Austria, N. Italy. B.M. 1176. L.B.C. 9:892. G.C. III. 36:217; 50:163. Gn. 21, p. 421. J.H. III. 49:399. Var. *albus*, Kirchn. Fls. white. G. 6:433. Var. *albo-carneus*, Kirchn. (var. *carneus*, Hort.). Fls. light pink. Var. *atropurpureus*, Dipp. Fls. dark purple. Var. *elongatus*, André (var. *pendulus*, Dipp.), with slender, pendulous branches and purple fls., is sometimes grafted high on *Laburnum*. There exists an interesting graft hybrid of this species and *Laburnum vulgare*, for which see *Laburnum Adamii*.

AA. Calyx campanulate, as long or only slightly longer than wide: branches grooved or angled.

B. Fls. axillary along the branches.

C. Lvs. simple: fls. yellow: procumbent shrubs. (*Coro-thamnus*.)

6. *decumbens*, Spach. Prostrate shrub, 4–8 in. high: branchlets 5-angled, glabrescent: lvs. oblong-obovate,

obtuse or acutish, pilose on both surfaces, ciliate,  $\frac{1}{3}$ – $\frac{3}{4}$  in. long: fls. yellow, 1–3; calyx sparingly pilose; standard broadly obovate,  $\frac{1}{2}$  in. broad: pod  $\frac{1}{2}$ – $\frac{3}{4}$  in. long, pilose, with 3–4 seeds. May, June. S. Eu. B.M. 8230. L.B.C. 8:718.

cc. *Lvs. 3-foliate (in Nos. 9 and 10 partly simple).*

d. *Plant a prostrate shrub: fls. yellow or yellowish white. (Trianthocytisus.)*

7. **Ardoinii**, Fournier. Prostrate shrub, about 1 ft. high: branchlets grooved, pubescent: lvs. long-petioled; lfts. 3, linear-oblong, acute, covered with spreading hairs,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long: fls. golden yellow, 1–3, crowded at the end of short lateral branchlets, nearly  $\frac{1}{2}$  in. long: pod very villous,  $\frac{3}{4}$  in. long. April, May. S. France. Moggridge, Flora of Mentone 58.—Very handsome, but tender.

8. **kewénsis**, Bean (*C. Ardoinii*  $\times$  *C. multiflorus*). Prostrate shrub: lfts. 3, linear-oblong, clothed with short soft pubescence,  $\frac{1}{3}$ – $\frac{1}{2}$  in. long: fls. yellowish white, 1–3, along slender branches,  $\frac{1}{2}$  in. long. May. Originated at Kew. Gn. 60, p. 348; 69, p. 282; 73, p. 228; 75, p. 273. G.M. 44:579; 51:355. G.W. 16, p. 610.—Like the preceding well adapted for rockeries or for forming a close covering to the ground.

dd. *Plant an upright shrub: foliage scarce.*

e. *Style slightly curved, shorter than keel: fls. white or yellowish white. (Spartothamnus.)*

9. **multiflorus**, Sweet (*C. albus*, Link, *C. Linkii*, Janka. *Spartium multiflorum*, Ait.). Shrub, to 3 ft., with slender, erect, grooved branches pubescent at first: lvs. short-petioled, 1- to 3-foliate; lfts. obovate-oblong to linear-oblong,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long, sparingly appressed-pubescent: fls. axillary, 1–3, white,  $\frac{1}{3}$ – $\frac{1}{2}$  in. long: pod appressed-pubescent, usually 2-seeded. May, June. Spain, N. Afr. Gn. 64, p. 251; 69, p. 92; 72, p. 276. G.M. 49:579. G.W. 5, p. 111. Var. **incarnatus**, Sweet. Fls. white, slightly blushed. L.B.C. 11:1052 (as *Spartium*).

10. **præcox**, Bean (*C. multiflorus*  $\times$  *C. purgans*). Shrub, to 10 ft., with slender upright or arching branches: branchlets grooved, pubescent at first: lfts. usually 1, sometimes 3, short-petioled, oblanceolate or linear-spatulate, silky pubescent,  $\frac{1}{3}$ – $\frac{3}{4}$  in. long: fls. 1–2, yellowish white, very numerous along the slender branches, nearly  $\frac{1}{2}$  in. long: pod appressed-pubescent, about 1 in. long, usually 2-seeded. May. Of garden origin. G.C. III. 29:41. Gn. 56, p. 37; 65, p. 438; 69, p. 318. G.M. 44:581; 52:183. M.D.G. 1903:265. G.W. 3, p. 221. Var. **albus**, Smith. Dwarfier, more pendulous: fls. white. Gn. 75, p. 192. Var. **luteus**, Smith. Dwarf: fls. yellow.—This hybrid is one of the most floriferous of all brooms.

11. **filipes**, Webb (*Spartocytisus filipes*, Webb). Shrub, with slender, angulate, thread-like branches: lvs. slender-petioled, 3-foliate, nearly glabrous; lfts. linear-lanceolate: fls. axillary, 1–2, fragrant, pure white; wings much longer than the keel. Feb.–May. Teneriffa.—As *C. palmensis*, Hort., in the American trade.

EE. *Style longer than keel, spirally incurved: fls. bright yellow or partly crimson, rarely pale, large. (Sarthamnus.)*

12. **scoparius**, Link (*Sarthamnus scoparius*, Wimm. *Spartium scoparium*, Linn.). SCOTCH BROOM. Shrub, to 10 ft., with erect, slender branches: lvs. short-petioled, 1–3-foliate; lfts. obovate or oblanceolate, sparingly appressed-pubescent,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long: fls. usually solitary,  $\frac{3}{4}$  in. long; calyx and pedicels nearly glabrous; pod brownish black, glabrous, villous only at the margin. May, June. Cent. and S. Eu. G. 25:169.—The tops are used for their sedative and diuretic properties. In Germany the fls. also are used medicinally. Var. **Andreanus**, Dipp. (*Genista Andreana*, Puissant).

Fls. yellow with dark crimson wings. R.H. 1886:373. Gt. 40:1342. R.B. 19:129. J.H. III. 32:462.—A beautiful and striking variety. Var. **albus**, Loud. (var. **pallidus**, Hort. var. **ochroleucus**, Zabel., var. **sulphureus**, Arb. Kew). With yellowish white or pale yellow fls. Gn. 61, p. 299; 65, p. 375. G.M. 44:580. Var. **pendulus**, Arb. Kew (*C. grandiflorus*, Hort., not DC. *C. cantabricus*, Hort., not Willd.). With slender pendulous branches. There is also a variety with double fls.—All the vars. are more tender than the type. The Scotch broom, *C. scoparius*, has become established in this country, as a naturalized plant, in waste places from Nova Scotia to Va.; and it is also reported from Vancouver Isl. It is also recommended by landscape gardeners for covering raw and broken places. Its yellow fls. and nearly bare sts. make a unique combination in the American landscape. Even when it kills to the ground in winter, it throws up its sts. again in the spring.

BB. *Fls. in terminal racemes, sometimes umbel-like, yellow: branches very leafy.*

c. *Foliage deciduous: branches terete: racemes very long and slender. (Phyllocytisus.)*

13. **nigricans**, Linn. (*Lembotropis nigricans*, Griseb.). Shrub, 2–4 ft., with erect, appressed-pubescent branches: lvs. long-petioled; lfts. obovate or oblong-obovate, glabrous above, appressed-pubescent beneath,  $\frac{1}{2}$ –1 in. long: racemes very long and slender, 3–8 in. long. June, July. Germany, N. Italy, Hungary. L.B.C. 6:570. B.R. 10:802. B.M. 8479. R.B. 26:3. Var. **elongatus**, Borkh. (var. **longespiciatus**, Hort.). Blooming again in fall at the top of the elongated fruiting racemes. R.H. 1891, p. 149 (as var. *Carlieri*).

cc. *Foliage persistent: branches grooved. (Telina.)*

d. *Lvs. distinctly petioled, obovate or obovate-oblong.*

e. *Racemes nearly capitate, 3–9-fl., at the end of short lateral branchlets.*

14. **monspessulanus**, Linn. (*C. candicans*, DC. *Genista candicans*, Linn.). Shrub, to 10 ft.: branches villous-pubescent when young: lvs. short-petioled, usually glabrous above, pubescent beneath; lfts. obovate or obovate-oblong, mucronulate,  $\frac{1}{3}$ – $\frac{3}{4}$  in. long: racemes 3–9-fl., short, leafy at the base; fls. fragrant, bright yellow: pod rufous-villous. May, June. Mediterranean, Canary Is. W.D.B. 1:80 (not good).

EE. *Racemes longer, 6- to many-fl., second, terminal and lateral.*

f. *Petioles  $\frac{1}{2}$  in. long or shorter; lfts. usually obovate, less than  $\frac{1}{2}$  in. long.*

15. **canariensis**, Kuntze (*Genista canariensis*, Linn.). GENISTA of florists. Fig. 1201. Much-branched shrub, to 6 ft., with villous-pubescent branches: lfts. cuneate, obovate or oblong-obovate, rounded at the apex, pubescent on both sides,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long: racemes usually many-fl., dense and rather short; fls. fragrant, bright yellow. May–July. Canary Is. A.F. 6:802. R.B. 26:229. Var. **ramosissimus**, Briquet (*C. ramosissimus*, Poir. *C. Attheyanus*, Hort.). Lfts. very small, glabrous above: racemes short, but numerous. L.B.C. 13:1201. B.R. 3:217.

16. **racemosa**, Nichols., not Marn. (*Genista formosa*, Hort.). Fig. 1202. Shrub, to 6 ft.: branches pubescent: lvs. rather long-petioled; lfts. oblong-obovate, mucronulate,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long, silky pubescent on both sides: racemes elongated, many-fl., second and rather loose, 2–4 in. long. Probably of garden origin and hybrid between *C. canariensis* and *C. maderensis* var. **magnifoliosus**. A. F. 6:802; 13:1136. F-E. 9:431.—Better florists' plant than the last; much grown as a pot-plant and forced for early spring and Easter. Var. **Everestianus**, Rehd. Fls. of a deeper shade of yellow, very free-flowering. R.H. 1873:300.

FF. Petioles  $\frac{1}{2}$  in. long or longer; lfts. oblong-obovate, about  $\frac{1}{2}$  in. long or longer.

17. *maderénsis*, Masferrer (*Teline maderénsis*, Webb). Shrub or small tree, to 20 ft.: lvs. slender-petioled, crowded; lfts. oblong-obovate, silky pubescent on both sides, or smooth above, acute or acutish,  $\frac{1}{8}$ – $\frac{3}{4}$  in. long; racemes 6–12-fld., rather short, fulvous or silky pubescent; fls. bright yellow, slightly fragrant; pod 5–7-seeded. May, June. Madera. Var. *magnifoliósus*, Briquet (*Teline stenopétala*, Webb. *C. stenopétalus*, Christ. *C. racemósus*, Marnock). Lvs. larger,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. long; racemes elongated, 10–20-fld. Madera. Marnock, Floricult. Mag. 2:19. B.R. 26:23 (as *Genista bracteolata*). Webb & Berthelot, Phytogr. Canar. 45.— Sometimes cult. as *C. splendens*, but less desirable as a greenhouse plant than the two preceding species.

DD. Lvs. nearly sessile, linear or linear-lanceolate.

18. *linifolius*, Lam. Shrub, to 3 ft., with erect, appressed-silky tomentose branches: lfts. linear or linear-lanceolate, acute, revolute at the margin, nearly glabrous and shining above, silvery pubescent beneath,  $\frac{1}{2}$ –1 in. long; racemes short and compact; fls. bright yellow; pod torulose. April–June. Spain, N. Afr., Canary Isls. B.M. 442.

*C. Adamii*, Poir.—*Laburnum Adamii*.—*C. alpinus*, Mill.—*Laburnum alpinum*.—*C. austriacus*, Linn. Allied to *C. supinus*. Lfts. narrow, oblanceolate, silky pubescent on both sides; fls. yellow; calyx densely villous. S.E. Eu., Caucasus.—*C. Bearii*, Nichols. (*C. Ardoinii*  $\times$  *C. purgans*). Low shrub with golden yellow fls., and narrow mostly simple lvs. G. 30:207.—*C. biflorus*, L'Her. = *C. ratibonensis*.—*C. cantabricus*, Willd. Allied to *C. scoparius*.

but prostrate, with silky lvs. and large bright yellow fls.: pod villous. May. Spain.—*C. congestus*, Ball (*Teline congesta*, Webb). Allied to *C. linifolius*. Densely villous-tomentose, small-lvd.: lvs. short-petioled; racemes short. Teneriffa.—*C. Dallimòrei*, Rolfe (*C. multiflorus*  $\times$  *C. scoparius* var. *Andreanus*). Upright shrub with pale purple fls. G.C. III. 51:198. Gn. 74, p. 291. G.M. 55:11. B.M. 8482. There are forms with sulfur-yellow and one with orange-yellow fls.—*C. elongato-purpureus*, Hort. = *C. versicolor*.—*C. elongatus*, Waldst. & Kit. = *C. ratibonensis* var. *elongatus*.—*C. emeriflorus*, Reichb. (*C. glabrescens*, Sartor. not Schrank). Allied to *C. Ardoinii*: Sparingly appressed-pubescent; branchlets angled; fls. yellow; pod glabrous. N. Italy. G.W. 15, p. 557.—*C. fragrans*, Lam. Allied to *C. filipes*. Petioles short; lfts. densely pubescent; fls. fragrant, white. Spring. Teneriffa. J.H. III. 50:448.—*C. glabrescens*, Sartor., not Schrank = *C. emeriflorus*.—*C. handsworthensis*, Paul & Sons. "A white-fld. plant suitable for the rockery."—*C. Hillebrandtii*, Briquet (*Genista Hillebrandtii*, Christ). A suffruticose species, with long, slender hairy sts. and trifoliate hairy lvs. Canary Isls.—*C. incarnatus*, Hort. = *C. versicolor*.—*C. Laburnum*, Linn. = *Laburnum vulgare*.—*C. nubigenus*, Link = *C. fragrans*.—*C. purgans*, Willd. Shrub, to 3 ft., appressed-pubescent; branches striped; lvs. 1–3-foliate, oblong or linear-lanceolate; fls. axillary, yellow, fragrant; pod glabrous. May–July. Spain, S. France.—*C. ramentaceus*, Sieb. = *Petteria ramentacea*.—*C. ratibonensis*, Schaeff. Allied to *C. hirsutus*. To 3 ft.: branches slender, appressed-pubescent; lfts. glabrous above, silky beneath; fls. 1–2, yellow; calyx with appressed, yellowish, silky hairs. April–June. M. Eu., W. Asia. Var. *elongatus*, Koch. More erect; fls. larger, 3–5; calyx with somewhat spreading hairs. B.R. 4:308 (as *C. biflorus*).—*C. sessilifolius*, Linn. Allied to *C. nigricans*. Quite glabrous; lvs. nearly sessile, with roundish-obovate lfts.: racemes short, 4–11-fld. May, June. S. Eu. B.M. 255.—*C. Spachianus*, Kuntze (*Genista Spachiana*, Webb). Closely related to *C. canariensis*. Taller: lfts. obovate, acuminate; racemes somewhat elongated. Canary Isls. B.M. 4195.—*C. triflorus*, L'Her. Similar to *C. hirsutus*. Fls. long-pedicelled, yellow; calyx-tube short, not tubular. April, May. S. Eu., N. Afr. Tender. F.C. 3:102.—*C. versicolor*, Dipp. (*C. hirsutus*  $\times$  *C. purpureus*). Low shrub, with sparingly villous lvs.: fls. yellowish white and pale purple. Sometimes cult. as *C. incarnatus*.—*C. Weldenii*, Vis. = *Petteria ramentacea*.

ALFRED REHDER.

1202. *Cytisus racemosus*.  
( $\times \frac{1}{2}$ )

# D

**DABŒCIA** (after its Irish name, St. Dabeoc's Heath). More commonly spelled Daboëcia, and sometimes Dabeocia. Syn., *Borëta. Ericacææ*. Shrub cultivated for its purple flowers appearing in summer.

Low evergreen with alternate entire lvs. and drooping pedicelled fls. in long terminal racemes: corolla ovoid, contracted at the mouth and shortly 4-lobed, with recurved lobes; stamens 8, included; caps. 4-celled, dehiscent.—One species in W. Eu.

This is a very pretty heath-like plant, with purple or white flowers in elegant loose racemes, well adapted for rockeries or borders of evergreen shrubberies. Requires protection North during the winter, and thrives best in a peaty, sandy soil. Propagated by seeds treated like those of *Erica*, and by cuttings of half-ripened wood under glass.

**cantábrica**, Koch (*D. polifolia*, Don. *Borëta cantábrica*, Kuntze. *Menziësia polifolia*, Juss.). IRISH HEATH. To 2 ft.: branchlets glandular pubescent: lvs. elliptic, the uppermost narrower, revolute at the margin, whitish tomentose beneath, shining and dark green above,  $\frac{1}{4}$ – $\frac{1}{2}$  in. long: racemes many-fl.; corolla  $\frac{1}{8}$ – $\frac{1}{2}$  in. long, purple in the type. June–Oct. Ireland, W. France, N. Spain, Azores. Gn. 52:344; 71, p. 442; 76, p. 490. Gn. M. 3:336. R.B. 3:121. Gt. 47:1450. S.B.F.G. 2:276.—There are many varieties, as *alba*, Dipp., with white fls. (Gn. 22, p. 302); *bicolor*, Dipp. (var. *striata*, Hort.), with white- and purple-striped fls.; *rosea*, Rehd. (*Borëta cantábrica rosea*, Koopmann), with pink fls.; *atropurpurea*, Dipp., with dark purple fls.; *nana*, Rehd. (*Menziësia polifolia nana*, Lodd. *M. polifolia pygmæa*, Arb. Kew). Dwarf; with small and narrow lvs. L.B.C. 20:1907.

ALFRED REHDER.

**DACRÝDIUM** (Greek-made name, referring to the tear-like exudations). *Taxacææ*. About 16 species of New Zeal., Austral., Malaya and Chile, being trees or shrubs with closely imbricated scale-like lvs. on old trees and linear or linear-subulate spreading lvs. on young trees and lower branches, none apparently in the trade in this country but more or less grown in European arboreta; allied to *Podocarpus*, from which it differs in having dimorphic lvs., peduncle of fr. dry or fleshy (fleshy and enlarged in *Podocarpus*), and the ovule becoming erect; and to *Phyllocladus*, which differs in having cladophylla and the true lvs. reduced to minute scales. *Dacrydium* is dioecious or rarely monœcious, the fls. not in cone-like structures; male fls. solitary at tips of branchlets and with the uppermost lvs., females nearly or quite terminal under the lf.-like scales: seeds nut-like, ovoid, borne in a cup-like fleshy or thin aril.—These more or less spruce-like trees sometimes attain a height in their native

regions of 75–100 ft. Some of the species may be expected to thrive in the southern areas.

**DÁCTYLIS** (Greek *daktulos*, a finger). *Graminææ*. A perennial tufted grass with flat blades, thin prominent ligules and sheaths closed nearly to the throat, grown for forage and one form for ornament.

Panicles glomerate; spikelets 2–5-fl., nearly sessile in dense 1-sided fascicles, these arranged in a panicle; lemmas hispid-ciliate on the keels, awn-tipped, compressed.—Species 1, north temperate regions of the Old World.

**glomerata**, Linn. ORCHARD-GRASS. Fig. 1203. A coarse grass, 2–3 ft., forming large tussocks: panicle a few stiff branches, expanding in fl., afterwards appressed. Dept. Agric., Div. Agrost. 20:145.—Commonly cult. as a pasture and meadow grass and useful for lawns under trees. Var. *variegata*, Hort., is a dwarf form of compact habit with foliage variegated silver and green; used for borders. Prop. by division; of easy cultivation.

A. S. HITCHCOCK.

**DACTYLOCTËNIUM** (Greek, *daktulos*, finger, and *ktenion*, a little comb). *Graminææ*. FINGER-COMB GRASS. Annual grasses with spreading or creeping stems, one of which has been offered as an ornamental subject.

Spikelets several-fl., sessile, crowded in 2–6 digitate 1-sided, rather broad, flattened spikes; axis of spike extending beyond the spikelets as a naked point. Species 2, warm regions of the Old World. One species, *D. ægyptium*, Richt. (*D. ægyptiacum*, Willd. *Eleusine ægyptica*, Desf. *Cynosurus ægyptius*, Linn.), Crow-Foot, is a common weed in Trop. Amer. The 3–5 short spikes are divaricate at the summit of the culms, about 2 in. long.—It has been offered as an ornamental grass for garden cult., but has little value. Mojave Indians of S. Calif. use the grain for food. In Afr. a decoction is prepared from the seeds for inflammation of the kidneys.

A. S. HITCHCOCK.

**DÆDALACÁNTHUS** (Greek words, signifying an *acanthad* of curious structure). *Acanthacææ*. Tropical shrubs or sub-shrubs, with blue or rose-colored flowers, sometimes grown under glass and in the open in warm countries.

Leaves entire or scarcely dentate: fls. in bracted spikes which are sometimes paniculate, the bracts usually much exceeding the calyx; calyx deeply 5-lobed or -parted; corolla-tube elongated and slender, more or less curved, bearing an oblique spreading 5-lobed limb; perfect stamens 2, affixed in the throat, included; style slender and recurved: fr. an ovate or oblong caps., the seeds 4 or fewer.—Some 15 to 20 species in E. India and Malay Archipelago; by some authors the name *Eranthemum* is applied to these plants

1203. Orchard-grass.—*Dactylis glomerata*. (plant  $\times \frac{1}{2}$ )

and what are known as *Eranthemum* in this work then become *Pseuderanthemum*.

This genus contains some tender shrubs of rather difficult culture under glass, but great favorites in the tropics, particularly in India. *D. nervosus* is a popular winter- and spring-blooming shrub in southern Florida. It has blue flowers an inch across, five-lobed, and shaded purple at the mouth of the tube. For culture, see *Justicia*.

**nervosus**, T. Anders. (*Eránthemum nervosum*, R. Br. *E. pulchellum*, Andr., and some dealers, while that of others is *E. bicolor*, and that of Roxburgh is *D. purpurascens*). Fig. 1204. Glabrous or very nearly so: lvs. ovate or elliptical, acuminate at both ends, somewhat crenate or entire: spikes axillary, opposite, overlapping and interrupted: bracts elliptical, acute, nervose: limb of the corolla as wide as the tube is long. India. B.M. 1358 (as *Justicia nervosa*). Gn. 51:352. G.C. II. 21:415.—A very pretty shrub for the warm-house, 2-6 ft., its fls. being of a color that is not very common in winter-blooming plants. It is an easy subject to manage, requiring a light, rich soil, full sunlight and plenty of water. Cuttings of young growth root readily in a warmhouse.

**macrophyllus**, T. Anders. St. pubescent toward top: lvs. elliptic-lanceolate, ovate-acuminate, attenuate at base: spikes linear, somewhat interrupted: bracts elliptic, rather obtuse, nervose: fls. pale violet-blue. India. B.M. 6686.—Differs from *D. nervosus* in laxer infl., hairy lvs. which are scabrid-pubescent on the nerves beneath, and more pubescent shoots.

**Wáttii**, Bedd. (*D. párvus*, C. B. Clarke). Slender, 2 ft.: lvs. deep green with a light metallic shade, very broad-ovate: fls. 1 in. across, blue or violet-blue, the corolla-lobes broad-obovate and narrowed abruptly to a point, the white stigma protruding from the narrow throat. India. G.M. 44:645. G.C. III. 32:311. A.F. 17:382.—A good dwarf species with fls. in dense clusters, blooming in pots when 1 ft. high and flowering in Sept. Requires a warmhouse treatment; grows well in sandy loam; prop. by cuttings. L. H. B.†

**DÆMÓNOROPS** (probably means *God-like*, of *divine appearance*). *Palmææ*, tribe *Lepidocárpeæ*. Slender pinnate palms grown for their graceful foliage, but little known in Amer. outside of botanic gardens. Differs from *Calamus* (with which it is by some united) only in having the outer sheaths or spathes boat-shaped, deciduous, at first inclosing the inner sheaths; its more longly stalked fls. also separate it from *Calamus*.—About 85 species, all Trop. Asiatic. Only a very few are in cult. Treatment and general cultural conditions of *Calamus*. *D. Draco* produces some of the "dragon's blood" of commerce. See page 3568.

A. *Young lvs. green.*

B. *Sts. erect or climbing, sometimes both in one plant.*

**calicárpus**, Mart. (*Calamus calicárpus*, Griff.). St. erect or climbing, 1 in. diam.: lvs. 6-8 ft. long, upper small with long flagella; lfts. numerous, 12-13 in. long,  $\frac{1}{3}$ - $\frac{1}{2}$  in. wide; petiole 1 ft., the base not gibbous or puckered: fr. about  $\frac{3}{4}$  in. diam., tawny. Malacca.

**melanochætēs**, Blume. St. erect: lvs. pinnate, 10-12 ft. long in nature, the pinnae long and narrow, dark green and drooping, furnished with many cirrhi, the petioles sharp-spined at the sheathing base: fr. yellow-green. Malaya.—Very decorative. A small form is var. *microcárpus*. Little known in U. S.

BB. *Sts. always climbing.*

**Lewisianus**, Mart. (*Calamus Lewisianus*, Griff.). St. climbing, 1 in. diam.: petiole 1 ft., base much swollen, armed below with scattered, short, deflexed spines, and above with straight and hooked spines  $1\frac{1}{4}$  in. long; lfts. 13-15 in. long,  $\frac{3}{4}$ -1 in. wide; sheath

armed with solitary or seriate flat-back spines: fr. pale yellowish. Penang.

**intermèdeus**, Mart. St. 15-20 ft.,  $\frac{3}{4}$  in. diam.: lvs. long-petioled, 4-6 ft. long; lfts. opposite or scattered, 18-20 in. long, 1-1 $\frac{1}{2}$  in. wide, linear-lanceolate, acuminate, margins and 3-5 costæ bristly above and below;

1204. *Dædalacanthus nervosus*. (× $\frac{1}{3}$ )

rachis semi-cylindrical, sparingly armed; petiole 1 ft. long, with flattened spines. Malaya.

AA. *Young lvs. brownish or straw-colored.*

**palembánicus**, Blume. St. erect: lvs. pinnate, broadly ovate, bright cinnamon-brown when young, and lfts. many, long, narrow, 1 $\frac{1}{2}$  ft. long, about  $\frac{1}{2}$  in. wide; petioles erect, with stout spines on the back, which are deflexed and not thickened at the base and are arranged singly or in series. Sumatra. F. 1873, p. 136.

**periacánthus**, Miq. Height 15 ft.: resembles *D. palembanicus*, but the young lvs. are nearly straw-colored, and the spines are placed in irregular rings. Sumatra.—A most graceful species.

*D. plumosus*, Hort. Graceful plume-like lvs., with pinnae 4 ft. or less long; petioles with rigid black spines with white bases. India. F. 1871, p. 39.—Not in cult. in N. Amer.

JARED G. SMITH.  
N. TAYLOR.†

DAFFODIL: *Narcissus*. Daffodil, Sea: *Pancratium*.

**DÁHLIA** (named after Professor Andreas Dahl, a Swedish pupil of Linnæus, and author of "Observationes Botanicae"). Syn. *Georgina*. *Compósitæ*. Stout perennial herbs, sometimes somewhat woody, much grown out-of-doors for the rich and profuse autumn bloom. Plate XXXIV.

Tuberous-rooted (Fig. 1205): st. mostly erect, branching, glabrous or scabrous: lvs. opposite, 1-3-pinnate: heads long-peduncled, large, with yellow disk and rays in a single series and mostly in shades of red and purple and also in white (in cult.); ray-fls. neutral or pistillate, disk-fls. perfect and fertile; involucre double, the inner series of thin scales that are slightly united at base, the exterior series smaller and somewhat leafy;

receptacle plane, bearing chaffy scales; rays spreading, entire or minutely 3-5-dentate; fr. oblong or obovate, strongly compressed on the back, rounded at the apex, obscurely 2-toothed or entirely bald.—Probably 10 or 12 species, in the higher parts of Mex., some of them now much modified by cult., and the domesticated forms often difficult of systematic study. The nomenclature of the group is confused because systematists are not agreed on the rank to be given to forms that have received independent names. Voss (*Blumengärtneri*) combines the three species of Cavanilles, *D. pinnata*, *D. coccinea*, and *D. rosea*, all under the name *D. pinnata*. His arrangement is as follows: *D. pinnata*, Cav.; var. *coccinea*, Voss (*D. coccinea*, Cav. *D. rosea*, Cav., in part. *D. frustanea*, DC. *D. crocea*, Poir. *D. bidentifolia* and *D. mexicana*, Hort.); var. *gracilis*, Voss (*D. gracilis*, Ort.); var. *Cervantesii*, Voss (*D. Cervantesii*, Lag.); var. *variabilis*, Voss (*D. variabilis*, Desf. *D. rosea*, Cav., in part. *D. sambucifolia*, Salisb. *D. superflua*, Ait. *D. purpurea*, Poir.). It seems to be well, however, to keep *D. rosea* and *D. coccinea* distinct, and perhaps also *D. pinnata*; and this is the method adopted for the present treatment. Of the three Cavanillesian names, *D. pinnata* has priority.

A. Plant very tall, tree-like.

B. Fls. nodding, bell-shaped.

*imperiælis*, Roezl. Height 6-18 ft.: sts. usually many from one base, mostly unbranched, knotty, 4-6-angled, usually dying to the ground in winter in S. Calif.: lvs. 2-3-pinnately parted; lfts. ovate, narrowed at the base, acuminate, toothed, with a few short scattered soft hairs; fls. nodding, 4-7 in. across, white, more or less tinged with blood-red, especially at the base; rays sterile or pistillate, lanceolate, sharp-pointed, not 3-toothed at the apex. Gt. 1863:407; 56, p. 22. G.C. 1870:459; II. 12:437; III. 34:178. B.M. 5813. Gn. 12:352; 33, p. 527; 61, p. 40. R.H. 1872:170; 1911, pp. 62-3. A.G. 15:313. Mn. 8, p. 61.—As few conservatories can make room for so large a plant, it is common to graft this species on dwarf varieties of *D. rosea*. The inflated and pointed fl.-buds (3-4 in. long) are very characteristic. It is not known whether the original plant collected by Roezl was found in wild or cult. surroundings. This species and the next are mostly cult. under glass if cult. at the N., but this species thrives in the open in Cent. Calif.; the others are grown outdoors in summer, and the roots stored in winter. Hybrids are reported between this species and *D. excelsa*.

BB. Fls. erect, not bell-shaped, but opening out flat.

*excelsa*, Benth. (*D. arborea*, Regel). Height to 20 ft. or more: sts. several from same base, usually

1205. Clustered roots of the garden dahlia.

beneath, with a few short scattered hairs or none; fls. 4½ in. across, dilute purple, crimson-pink. G.C. II. 19:80; III. 27:85.—This species was described from a cult. plant with 8 rays in a single row, but with considerably elongated disk-fls. It was almost an anemone-fl. type, and all the florets were sterile. *D.*

*arborea* has never been sufficiently described as a botanical species, but plants have been cult. for many years under this name. Var. *anemonæflora*, Hort. Disk of lilac or yellow tubular florets; rays flat.

AA. Plant medium, averaging 3 ft., commonly from 2-5 ft., rarely exceeding these extremes.

B. Lvs. once pinnate: st. not branching from the base: habit erect.

c. St. usually not glaucous: rays fertile.

D. Rays of the single fls. not recurved at the margins; of the double fls. never flat, but cupped.

*rosea*, Cav. (*D. variabilis*, Desf. *D. Barkeriæ* and *D. Royleana*, Knowl. & Westc.? *D. superflua*, Ait.

1206. *Dahlia rosea* (or *D. variabilis*). (× ½)

*D. purpurea*, Poir. *D. nana*, Andr. *D. crocata*, Lag. *D. coronata*, Hort.). Fig. 1206. Lvs. typically once pinnate, sometimes bipinnate; lfts. ovate, toothed, broader and coarser than in the other species. B.R. 55. B.M. 1885.—The original of practically all the old-fashioned dahlias, particularly the Single, Pompon, Show and Fancy types. It is therefore the parent of the vast majority of the horticultural varieties. This is a wonderfully variable species. Some plants are densely hairy, others scarcely at all. The lvs. are sometimes bipinnate in parts of plants or throughout an entire plant. In double forms the rays usually have abortive pistils. Many garden forms have glaucous sts. Some authors have doubted whether this species is distinct from *D. coccinea*, but the two types are very different in the garden, although there are intermediate forms in nature.

DD. Rays of the single fls. with recurved margins; of the double fls. not cupped, but long, flat and pointed, and some at least with recurved margins.

Juarézii, Hort. (*D. Yuarézii*, Hort.). CACTUS DAHLIA. Fig. 1207. Distinct in the bloom: heads bril-

XXXIV. Dahlia.—Jeanne Charmet, one of the most beautiful Decorative dahlias.

liant scarlet; fls. irregular in length and overlapping, the rays narrow. The Cactus dahlias all originated from one plant, which was flowered in Eu. for the first time in 1864, and first pictured in G.C. II. 12:433 (1879). F.M. 1879:383. Gn. 18, p. 589; 19:742; 56, p. 236. G.Z. 26:49.

cc. *St. glaucous*: rays not fertile.

**coccinea**, Cav. (*D. bidentifolia*, Salisb. *D. Cervantesii*, Lag. *D. Crœcea*, Poir.). Fig. 1208, redrawn from B.M. 762 (1804). Always more slender than *D. rosea*, with narrower lfts., and in the wild, at least, dwarfer than that species. The color range is much smaller, and does not include white or any shade of purple or crimson. The colors vary from scarlet, through orange to yellow. There are no double forms, and it has been said that this species will not hybridize with *D. rosea*. The named varieties pictured in I.H. 31:515 and 533 (1881), which are emphatically declared to be varieties of *D. coccinea*, are probably garden forms of *D. rosea*. The only characters that certainly distinguish *D. coccinea* from *D. rosea* are the glaucous sts. and infertile rays of the former, but these characters break down in garden forms. B.M. 762. Gn. 19:154. G.C. II. 12:525.

BB. *Lvs. twice pinnate*: sts. branched from the base: habit spreading.

**Mérckii**, Lehm. (*D. glabrata*, Lindl.). Fig. 1209, redrawn from B.M. 3878 (1841). Height 2-3 ft.: roots much more slender than those of *D. rosea*: st. and lvs. wholly devoid of hairs; lvs. bipinnate: floral bracts linear; fls. typically lilac; rays pistillate; outer involucre bracts linear. B.R. 26:29 (1840). Gn. 19:154 (1881).—This is a very distinct garden dahlia, and is worth growing merely as a foliage plant. The fine-cut character of the foliage makes it more attractive than the coarse foliage of most of the varieties of *D. rosea*. The plants are much dwarfer and wider spreading than most florists' dahlias, and show no st. while growing. The branched flowering sts. are remarkably long, slender and wiry, often rising 2-3 ft. above the foliage. The rays are very short and often roundish, with a short sharp point instead of 3 minute teeth. There are no red, yellow or white forms in nature. The roots of this and *D. coccinea*, being slenderer than those of *D. rosea*, must be preserved with greater care in winter.

*D. gracilis*, Ort. Lvs. bipinnate and ternately divided, glabrous, the lfts. small, ovate and coarsely toothed; fls. brilliant orange-scarlet; outer bracts of involucre almost orbicular: 4-5 ft., making a dense bush with very slender growths, bearing heads 2½-3 in. across. Apparently not in general cult.—*D. pinnata*, Cav. Plant scarcely 3 ft. high, glabrous: lvs. 5-foliate; lfts. ovate, crenate-dentate, glaucous beneath, sessile; rachis winged: fls. large, solitary; female corolla large, blue-red, exterior involucre with 6-7 bracts, ovate, narrowed toward the base, spreading and reflexed-incurved, the interior with coriaceous lobes. The plate of Cavanilles shows semi-double fls., i.e. with several rows of rays, with the rays incurved at the margin and becoming at the base nearly tubular.—*D. Zimapanii*, Roelz, is by some retained in Dahlia and by others referred to Bidens; in this work it is described under Cosmos (*C. diversifolius*).

WILHELM MILLER.  
L. H. B.†

### Types and varieties of the dahlia.

Practically all of the named varieties of dahlias have come from one immensely variable species, usually known as *D. variabilis*, but more properly as *D. rosea*. For garden purposes, however, a second form of great importance, *D. Jaurezii*, the parent of the Cactus forms, must be kept distinct. There are other species cultivated to a slight extent. It is curious that these showy plants should be closely related to a common weed, the beggar's tick, of the genus *Bidens*; but other species of Dahlia have leaves whose forms pass gradually into those of *Bidens*. Other close allies are *Cosmos* and *Coreopsis*. *Cosmos* flowers are some shade of purple, rarely white in wild nature, and only one species has yellow flowers; *Coreopsis* has yellow flowers

only; *Bidens*, yellow or white; and none of these genera has produced double-flowered forms of the first importance. Dahlia has all these colors and more, being far richer in bright reds, and lacking only sky-blue and its closely related hues, which are seen to perfection in the China asters.

Although dahlias are popular plants, especially in old gardens, they are destined to still greater popularity from the new "Cactus," "Decorative," "Peony-flowered," and "Collarette" types. There exists a prejudice against dahlias in many localities in which these new types have never been seen. This prejudice is part of a reaction against formal and artificial flowers in general. The old-time dahlias were round hard and stiff like a ball. The new-time dahlias are flatter, and tend toward loose, free, fluffy chrysanthemum-like forms. The dahlia has now become immensely variable.

Of the important and very variable florists' flowers, the dahlia was one of the latest to come into cultivation. The first break of considerable importance in the wild type occurred about 1814. Up to that time there were perhaps a dozen well-marked colors in good single-flowered varieties. Dahlias had been cultivated in Europe since 1789, and it is a curious fact that they showed signs of doubling the very first year of their European residence; but it was not until twenty-five years later that a marked gain in doubling was made. The dahlia seemed to be undeveloped until 1814, when the era of doubling began. Before another twenty-five years had passed, the dahlia had sprung into the front ranks of garden plants. In 1826 there were already sixty varieties cultivated by the Royal Horticultural Society. In 1841, one English dealer had over 1,200 varieties. Today it is not uncommon for the leading tradesmen to keep 500 to 1,000 distinct varieties. In the absence of good records, it is conjectured that over 3,000 different names of varieties have been published in the catalogues. Most of the varieties are the Show and Fancy types, which are as spherical and regular as possible, and differ only in color. At first the distinction between the two types

1207. The original Cactus dahlia.—*D. Jaurezii*.  
Reduced from the Gardeners' Chronicle, where  
it was first pictured

seems to have been the same as that between "self-colored" and "variegated" flowers in general. Lately, for purposes of exhibition in prize competitions, the following arbitrary distinction has been adopted: A Show dahlia (Fig. 1210) is often of one color; but if the edges of the rays are darker than the ground-color, the variety may be exhibited in the Show section. A Fancy dahlia (Fig. 1211) always has two or more colors, and if the rays are striped or if the edges are lighter than the ground-color, the variety must be exhibited in the Fancy section. The two types reached full perfection certainly by 1840, and after that date the improvements were mostly in matters of secondary importance. Most of the longest-lived varieties belong to the Show and Fancy type. These types held full popularity until about 1879, when the first Cactus dahlia appeared in England with a promise of new and freer forms. This form is the one which is perhaps farthest removed from nature, and it is probably so highly esteemed largely because the most work has been spent on it.

1208. *Dahlia coccinea*.  
Redrawn from the Botanical  
Magazine for 1804.

A reaction against formalism in all departments of life and thought set in about the time of the American Civil War. It was in the sixties that the Japanese chrysanthemums did much to emancipate the floral world. With dahlias the reaction came much later and has proceeded more slowly. The first Cactus dahlia was so called because of its resemblance in form, but chiefly in color, to the brilliant crimson-flowered *Cereus speciosissimus*, a well-known garden plant (which is known in the present work as *Heliocerus speciosus*). The name is now highly inappropriate because the color range of the pure Cactus type has been extended to include all of the important well-defined colors of which the dahlia seems capable. The original Cactus dahlia was named *Dahlia Juarezii*, after President Juarez, the "Washington of Mexico." It was pictured for the first time in the *Gardeners' Chronicle* for 1879, and this interesting picture is here reproduced in a reduced size in Fig. 1207. The type is still cultivated under the same name and in all essentials seems to be unchanged. Forms of the Cactus dahlia are shown in Figs. 1212, 1213.

The origin of the Cactus type, as of all the other types of dahlias, is uncertain, and our efforts to secure full and definite information upon some of the most interesting points may perhaps always be baffled.

A Dutch dealer secured a root from Mexico that produced one plant which is the parent of all the Cactus forms. It is not known whether the seed which may have produced the original root came from a wild or a cultivated flower. It has been said that seedlings of *D. Juarezii* have produced in cultivation forms approaching the Show type of *D. rosea*. The reverse process is also said to have taken place, but full, authoritative and convincing statements are wanting. In the garden, *D. Juarezii* is exceedingly distinct from the florists' forms of *D. rosea*. It is usually a slenderer, taller and longer-jointed plant, with much handsomer and more delicate foliage, the leaves being narrower than in the coarse and almost ugly foliage of the old forms. It has another peculiarity of growth, which is still one of the most serious defects in the true Cactus type: the plants tend to hide some of the flowers beneath their foliage. This comes about in a curious way. At a node between two young leaves there commonly appear, at about the same time three new growths; the middle one develops into a flower with a naked stalk only 2 or 3 inches long, while the side shoots quickly overtop it and repeat the same threefold arrangement. The other most serious objection to the true Cactus type is that it does not stand shipment well and does not last so long as a cut-flower as the Show dahlias.

The Decorative or Cactus Hybrid types are numerous, and their popularity is more modern. They have been largely seedlings from show flowers. Their rays are rarely, if ever, recurved at the margins. All the other types of dahlias are well defined, and a single picture of each one will represent its type with sufficient exactness. No one picture, however, can give any conception of the great variety of forms included in this more or less open horticultural section. The name Cactus Hybrid means practically "miscellaneous," and is analogous to the "Japanese" section of chrysanthemums. It is on this section and the pure Cactus type that the greatest hopes for the future of the dahlia are based.

Dahlias considered to be of true Decorative type are those possessing broad flat and nearly straight petals, arranged somewhat irregularly; but the flowers are not spherical in shape like the Show dahlia, but are inclined to be flat and massive, and are always full to the center. Dahlias of this character score a greater number of points at exhibitions.

The Colossal dahlia is the basis of much discussion, especially at exhibitions, the cause of debate being that these dahlias are in reality not classified; that is, the same variety is exhibited in one display as a Show dahlia, and in the next as a Decorative dahlia; but in reality there should be a Colossal class for this type of dahlia. This type, if it may be so called, has large cupped but not quilled rays or petals; the flowers are 5 inches and over in diameter, and spherical in shape; they therefore partake of both types, but are sufficiently different to spoil the harmony, when exhibited in either the Show or Decorative class. "Le Colosse" is the first of this type of dahlia, and hybridization has given a large number of seedlings, which are almost identical in form, shape, and size, the most prominent being at present American Beauty, Giant Purple or Royal Purple, J. K. Alexander, Surpasse Colosse, and Janne (Yellow) Colosse.

The Pompon type is a small form of the Show and Fancy types. It has the same colors and the same form, but the flowers are smaller and more abundant. As a rule, the smaller the flowers the prettier and more individual they are. The larger they are, the more they suffer by comparison with the Show type. Perhaps their greatest point is their productiveness. When profusion is the main idea, not great size and quality, the Pompons are the favorite type of dahlia for cut-flowers.

The Single dahlias may be freely produced, but they are not so lasting for cut-flowers. The Single type has had many ups and downs. In the reaction against formalism, it came to the front about 1881, and for several years thereafter several hundred forms were kept distinct and they were made the chief feature of

the European shows. When the dahlia first came into cultivation, its rays were relatively long, slender, acuminate, notched at the end, and with such wide spaces between the tips of the rays as to give the flower a stellate appearance. In the course of the evolution of the single type, the gardeners retained the most regular and symmetrical forms. Single dahlias with always and only eight rays were preserved. The rays of dahlias became broader and rounder, as in

1209. *Dahlia Merckii*.

Redrawn from the Botanical Magazine, for 1841.

Fig. 1214, until finally in pedigree varieties the vacant spaces were closed up. The same mental ideals have produced the rose-petaled geraniums and the shouldered tulips. In a high-bred single dahlia there are no minute teeth or notches at the tips of the rays.

Most of the single dahlias of high pedigree have rays of uniform coloration with no secondary color at the base, but a few have a distinct ring of color at the base, often called an "eye or crown," which is sometimes yellow and rarely red or some other color. Usually the rays of a single dahlia are spread out horizontally, sometimes they bend back, and rarely they bend inwards and form a cup-shaped flower. These three forms can doubtless be separated and fixed during those periods when the interest in the Single type warrants it. Semi-double forms are frequent (Fig. 1215).

Single dahlias are likely to lose some of their rays after a day or two in a vase. In cutting them it is well to choose the younger flowers. A vigorous shake often makes the older ones drop their rays. It is an easy matter to keep the seeds from forming, simply by removing the flowers as they mature, and by so doing save the strength of the plant for the production of flowers.

There are three other dahlia types of minor importance,—the Single Cactus, the Pompon Cactus and Tom Thumb. The Single Cactus type differs from the common Single type in having rays with recurved margins, which give a free and spirited appearance to the flowers. Instead of spreading out horizontally, the rays often curve inward, forming a cup-shaped flower. This type originated with E. J. Lowe, Chepstow, England, was developed by Dobbie & Co. about 1891, and was first disseminated in 1894. The Single Cactus dahlias are very interesting and pretty. The Tom Thumb type is a miniature race of round-rayed single dahlias, which grow from 12 to 18 inches high, and are used for bedding. The type originated in

England with T. W. Girdlestone, and was developed and introduced by Cheal & Sons.

The "green" dahlia (*Dahlia viridiflora*, Hort.) is an interesting abnormal form in which the rays are partially or wholly suppressed, and the chief feature of interest is a confused mass of green, not resembling petals at all, but evidently a multiplication of the outer involucre scales, which, in the dahlia, are green, leafy bracts. The "green" dahlia is not unhealthy; it is as strong and vigorous as any of the other forms, but very unstable and variable, producing flowers of solid green color, others of green with small cup-shaped crimson-scarlet petals intermingled, and others of solid crimson-scarlet color, and all on the same plant. This freak was pictured as long ago as 1845 in G.C., p. 626; and again in G.C. III. 30: 294.

Another interesting variation which hardly ranks in present importance with the eleven types contrasted below is the lacinated form, which makes a very pretty though rather formal effect. Examples are Germania Nova, Mrs. A. W. Tait and its yellow variety among large double forms, and White Aster among the Pompons. In these cases, the notches at the tips of the rays, instead of being minute and inconspicuous, are deepened so much that they give the lacinated effect. At present this form is available in a very narrow range of colors. It is not probable that it will be an important factor in producing chrysanthemum-like forms.

Another form which baffles description, but is nevertheless very distinct, is that of Grand Duke Alexis. It is nearer the Show type than any other, but is perhaps best classed with the Cactus Hybrid section, simply because it seems advisable to keep the Show type the most sharply defined of all. It is a very flat flower, and the rays are remarkably folded, leaving a round hole at the top of each one. Up to 1909 the variety of colors of the type of Grand Duke Alexis has been increased, including the varieties Dreer White, Mrs. Roosevelt, Purple Duke, Pythias, W. W. Rawson, and Yellow Duke.

About midway between Grand Duke Alexis and the Show or cupped type is an interesting form, the "quilled" dahlia, a name which is perhaps necessary, though unfortunate. In A. D. Livoni the rays are rather tightly folded for about two-thirds of their length, leaving a round hole at the tip as in Grand Duke Alexis, but giving a peculiar whorled effect, which plainly shows the spiral arrangement of the successive tiers of rays. Among Pompons, Blumenfalter is an example of this rosette-like or quilled form, and many colors are procurable. However, the word "quilled" usually suggests a long tube with a flared opening, whereas in the form described above the margins of the ray are merely rolled tightly together, but not grown together into a thin seamless tube. Perhaps the most important variation that has not yet appeared in the dahlia is the wonderful elongation of the disk florets

1210. A Show dahlia.

into long, thin, variously colored tubes which have produced such charming effects in the China aster and have culminated in the marvelous grace of many chrysanthemums. The dahlia may not be denied such possibilities, for in G.C. III. 20:339 (1896) a new dahlia was described in which the quills are really tubes for two-thirds of their length.

The Collarette dahlia is a very novel and distinct type. The flowers are single, with an additional row of short petals around the disk, which forms a frill or collar usually of a different color from the remainder of the flower. The same method obtained in the development of the Collarette dahlia as in the development of the Single dahlia. Varieties having only eight rays or petals, with the additional collar, and presenting a symmetrical and concentrated impression, were preserved. The collar consists principally of three or four smaller and more gracefully curved rays, produced at the disk, at the center of each of the eight larger rays or petals, and taking the same direction as the large rays, thus showing distinctly the golden yellow center, so pronounced in the Single dahlia. The first Collarette dahlia was President Viger, and was originated at Parc de la Tete d'Or, or in the gardens of the City of Lyons, France, then under the supervision of Professor Gerard, who was succeeded by M. Chabannes. President Viger was first shown in 1900 at the Universal Exposition, and offered for sale in 1901 by Rivorie Pere & Fils of Lyon. In 1902 appeared the variety Joseph Goujon also obtained at the Parc de la Tete d'Or, Lyon; then in 1903 Rivorie offered Etendard de Lyon and Gallia, which figured with honor for that firm. During the next ten years, from 1903 until 1913, all the known varieties of the Collarette dahlia were developed by Rivorie Pere & Fils, and appeared in the following order: 1903, Etendard de Lyon, and Gallia; 1904, Mme. LePage Viger, La Fusee, Duchesse J. Melsi D'Ehril-Barbo, Prince Galitzine, Comte Cheremeteff, and Maurice Rivoire; 1905, Exposition de Lyon Orphee, and Prince de Venosa;

1211. A Fancy dahlia of the Pompon type. ( $\times \frac{1}{2}$ )

1906, Merveille de Lyon, Mme. Georges Bernard, Comte Nodler, Deuil de Brazza, Princesse Olga Altieri, Corbeille de Feu, and Signorina Rosa Esen-grini; 1907, Comtesse Dugon, Ami Cachat, and Volcan; 1908, Jupiter, Pluton, Pan, Etoile de Moidiere, and Mme. Chamrion; 1909, M. Mery de Montigny;

1212. A Cactus dahlia. ( $\times \frac{1}{3}$ )

1910, Abbe Hugonnard, Comte de Vezet, Mme. Pile, Souvenir de Bel-Accueil, and Vicomtesse des Mons; 1911, General de Sonis, and Deuil du Docteur Ogier; 1912, Cocarde Espagnole, Etincelant, and Stella; 1913, Geant de Lyon, Maroc, and Etoile de Mon-plaisir. In 1912, J. K. Alexander, a dahlia specialist in East Bridgewater, Massachusetts, succeeded in developing the first Collarette dahlia of American origin, the variety Champion; this added the red and yellow coloring to the type. Previous to 1912, three other foreign varieties, Directeur Rene Gerard, Mme. E. Poirier, and Souv. de Chabanne, found their way to America, and were offered the following year in the leading seedsmen's catalogues. The year 1913 gave a collection of nearly fifty distinct named varieties of the Collarette dahlia, including every known color in the dahlia world.

The Holland Peony-flowered dahlia is now the most popular dahlia, possessing an entirely original form, resembling the semi-double peonies; the flowers are broad, flat, somewhat irregular in form, and are produced with remarkable freedom on long stems. This type of dahlia has proved the most satisfactory for garden purposes, the plants being covered with flowers the entire season. The origin of the Holland Peony-flowered dahlia, like all other types, is uncertain, and all efforts to secure full and definite information are unfruitful. Originally the Holland Peony-flowered dahlia was grown for some years in Germany in a mixture known as "Half-double Giant Dahlias." A Dutch grower, H. Hornsveld of Baarn, Holland, was

the first to note their possibilities, and selected from these "mixed dahlias" the best varieties, from which he propagated; then he drew the attention of the public to his new varieties, which he named and offered for sale. Other growers in Holland followed his example with great success. The Holland Peony-flowered

dahlia was imported to America in 1908, and simultaneously appeared in the catalogues of the leading growers and seedmen. The number increased rapidly, and in 1910 appeared new varieties of American origin, notably the new varieties originated by the W. W. Rawson Co., of Boston, Massachusetts. The most prominent varieties are the following: Andrew Carnegie (1908), Bertha Von Suttner (1908), Caesar (1911), Cecilia (1911), Dr. K. W. van Gorkum (1906), Dr. Peary (1911), Duke Henry (1906), Geisha (1908), Germania (1906), Glory of Baarn (1906),

1213. Single cactus dahlia. ( $\times \frac{1}{2}$ )

Glory of Groenekan (1907), H. Hornsveld (1907), Hugo de Vries (1907), H. J. Lovink (1911), Kaiserin Augusta Victoria (1907), King Edward (1909), King Leopold (1906), La Rainte (1907), Mannheim (1908), Merveille (1907), Miss Gladys Dawson (1908), Paul Kruger (1906), P. W. Jansen (1907), Queen Alexandra (1909), Queen Emma (1906), Queen Wilhelmina (1906), Snow Queen (1907), and Sherlock Holmes (1912).

The fragrant dahlia is the pride of the true Peony-flowered type, possessing a pleasing and agreeable odor, so long desired. The fragrant dahlia was first detected by J. Herbert Alexander, in the year 1912, on the trial-grounds of J. K. Alexander of East Bridgewater, Massachusetts; hybridization and propagation was begun immediately with the new variety, and in 1913 a collection of five fragrant dahlias appeared in Alexander's catalogue.

The main types of dahlias may perhaps be distinguished more clearly by the following scheme:

A. Plants very dwarf.

1. THE TOM THUMB TYPES.

AA. Plants not very dwarf.

B. Fls. single.

c. Rays flat, not recurved at the margins.

2. THE SINGLE TYPE. Fig. 1214.

CC. Rays with recurved margins.

3. THE SINGLE CACTUS TYPE. Fig. 1213.

BB. Fls. double.

C. Size of fls. small, 1-2 in. across.

D. Rays cupped.

4. THE POMPON TYPE. Fig. 1211. Also called "Bouquet" and "Lilliputian."

DD. Rays flat.

5. THE POMPON CACTUS TYPE.

CC. Size of fls. large, 3-5 in. across, averaging 4 in.

D. Rays cupped.

E. Colors single, or the edges darker than the ground-color.

6. THE SHOW TYPE. Fig. 1210.

EE. Colors 2 or more, striped, or with edges lighter than the ground-color.

7. THE FANCY TYPE.

DD. Rays not cupped, but long and flat, or with recurved margins.

8. THE CACTUS TYPE. Figs. 1207, 1212.

DDD. Rays various in form.

9. THE DECORATIVE TYPE.

10. THE COLLARETTE TYPE.

11. THE PEONY-FLOWERED TYPE; including the fragrant dahlia. Fig. 1215.

Useful dahlias for various purposes, as they exist in North America in 1913:

*Cactus dahlias, for cut-flower purposes.*—Alexander, Alight, Alfred Vasey, Clara G. Stedwick, Countess of Lonsdale, Dainty, Effective, Eureka, Floradora, Forbes Robertson, Flame, Glory of Wilts, Golden Gem, Gazelle, Gabriel, Gen. Buller, Helene, Henri Cayenx Hereward, Ivernia, Jeannette, J. H. Jackson, J. Weir Fife, Killarney, Lightship Lady Fair, Lady Colin Campbell, Lord of the Manor, Mary Service, Mrs. Deluca, Mrs. H. L. Brouson, Mrs. Winchester, Mrs. Mortimer, Mrs. Geo. Caselton, Mme. Henri Cayeux, Mrs. MacMullan, Reine Cayeux, Rosa Starr, Reliable, Stella, Sirus, Sandy, Thomas Wilson, and Yonne Cayeux.

*Cactus dahlias for exhibition purposes.*—Amazon, Clincher, Diavolo, Master Carl, Mercury, Mrs. S. T. Wright, Rev. Dr. Baker, Rev. T. W. Jamieson, Royal Scarlet, Schneewitchen, Snowstorm, T. G. Baker, Wellington, Whirlwind, White Swan, Wm. Marshall, W. B. Childs.

*Decorative dahlias for cut-flower purposes.*—Delice, Himmlische, Jack Rose, Jeanne Charmet, John R. Baldwin, Minos, Maid of Kent, Mme. A. Lumiere, Mme. Victor Vassier, Mme. Van den Dael, Perle de la Tete D'or, Reggie, Souv. de Gustave Douzon, Wilhelm Miller.

*Decorative dahlias for exhibition purposes.*—American Beauty, A. E. Johnson, Blue Oban, Gigantea, Grand Duke Alexis, Gettysburg, Le Grand Manito, Le Mont Blanc, Les Allices, Mme. Helene Charvet, Mme. Augusta Lumiere, Mademoiselle Galy Miquel, Madame Devinat, Mme. Marze, Morocco, Peerless, Perle de Ocean, Papa Charmet, Ville de Lyon, Yellow Colosse.

*Peony-flowered dahlias for cut-flower purposes.*—Admiration, Bertha Von Suttner, Goddess of Fame, Geisha, Marie Studholme, Mrs. A. Platt, Mrs. Jacques Futrelle, Queen Wilhelmina, and Sunrise.

*Peony-flowered dahlias for exhibition purposes.*—Hampton Court, King Leopold, Priscilla, Snow Queen, Solfatara, Duke Henry, and Hollandia.

*Collarette dahlias for massing.*—Exposition de Lyon, Maurice Rivoire, and President Viger.

*Show dahlias for exhibition purposes.*—Acquisition, Alice Emily, Acme of Perfection, Brown Bess, Dreer's White, Dr. Keynes, David Johnson, Emperor, Ivanhoe, Harrison Weir, Mrs. Susan Wilson, Mme. Heine Furtado, Mme. Marika Anagnostaki, Mme. Alfred Mareau, Merlin, Muriel, Norma, Nugget, Queen of Autumn, Rosebud, Stradella, Standard, W. P. Laird, and Wm. Dodds.

*Among the Show dahlias that are the best for flowering are:* A. D. Livoni, Arabella, Ansonia, Dr. J. P. Kirkland or Cuban Giant, Dorothy Peacock, Imperial, Miss Fox, Perfection, Storm King, and White Queen.

*Show dahlia for bedding purposes.*—White Bedder.

*Fancy dahlias of merit.*—Chorister, Chas. Turner, Dazzler, Dorothy, Distinction, Duchess of Albany, English Dandy, Eric Fisher, Gloire de Guiscard, Frank Smith, Frederick Smith, General Grant, Gold Medal, Goldsmith, Geo. Barnes, Hercules, Les Amours de Madame, Lucy Faucett, Mme. Lily Large, Polly Sandall, Rebecca, Rev. J. B. McCamm, S. Mortimer, Sunset, and Wizard.

*Pompon dahlias for borders or hedges.*—Achilles, Crusoe, Darkness, Fascination, Mabel, Pure Love, Rosalie, Red Indian, Snow Clad, Vivid, and Winifred.

*Pompon dahlias for exhibition purposes.*—Amber Queen, Ideal, Harry, Little Mary, Rosebud, Shalii, and Spy.

*Pompon dahlias for flowering purposes.*—Klein Domitea, Darkest of All, Fairy Queen, Star of the East, and Spy.

*Societies and shows.*

—The dahlia is one of about a dozen

1214. A broad-rayed single dahlia. ( $\times \frac{1}{2}$ )

genera of plants whose horticultural value has been attested by permanently successful special societies. There are national dahlia societies in England and America. Dahlia shows are usually held the second or third week in September. On December 21, 1906, the New England Dahlia Society was chartered; this Society led to great advancement in the dahlia, holding an annual exhibition in Boston, and issuing monthly a paper known as the "Dahlia News." Great interest was fostered, and in 1913 its membership list included nearly every state in the Union, and six foreign countries. At the present date of writing the New England Dahlia Society is considering the adoption of a new charter, whereby it can become the National Society. Other societies devoted to the welfare of the dahlia have been recently formed; principally "The Dahlia Association of Seattle," "Tacoma Dahlia Society," "Inter-town Dahlia Association" in Connecticut.

*Literature.*—As in many other cases, the magazine literature of the dahlia is the most bulky, and, in some respects, more important than the books on the subject. C. Harman Payne published a bibliography in G.C. III. 21:329 (1897). There had been about twenty-five books devoted to the dahlia, many of them pamphlets and cheap cultural manuals. These books were mostly published from 1828 to 1857, with none in North America for nearly forty years after that date until 1896, when Lawrence K. Peacock's book, "The Dahlia," appeared. The first American treatise was by E. Sayers, published at Boston, 1839. Many interesting facts came out in 1889, the centennial year of the dahlia. A report of the National Dahlia Conference is reprinted from the Journal of the Royal Horticultural Society for 1890, but Shirley Hibberd's statements therein regarding the botany of the dahlia agree very poorly with Hemsley's revision of the genus in G.C. II. 12:437, 524, 557 (1879). In 1906 W. W. Wilmore published "The Dahlia," a handsomely illustrated American manual, valuable to both amateur and professional. The annual catalogues of the leading dahlia specialists furnish much valuable matter, and cultural hints, and are the most up-to-date issues in the dahlia line.

WILHELM MILLER.  
J. K. ALEXANDER.

### Cultivation of the dahlia.

The dahlia has no very special or particular requirements, and yet many growers fail of the best success because the few demands are not well met.

#### *Propagation.*

There are four methods by which dahlias are propagated: by cuttings (the commercial method), by division of roots (the amateur's method), by grafting to perpetuate rare kinds, and by seeds, to produce new varieties.

*Cuttings.*—Propagation by cuttings is employed mainly by commercial growers, and though the amateur may propagate plants successfully, the attention a few cuttings would probably require is so great that it would be cheaper to buy plants. The roots are planted closely in benches in the greenhouse early in January, and cuttings are made from the young shoots as fast as they form the third or fourth set of leaves. These cuttings are carefully trimmed and placed in pure sand in the propagating-bench, using a dibble and putting the cuttings in rows about 3 inches apart and  $\frac{1}{2}$ –1 inch between the cuttings.

The propagating-bench is made by running a flue, hot-water or steam pipes beneath an ordinary bench, and boarding up the side to confine the heat. Although there may be a difference of opinion among propagators, yet a bottom of sand heat of 65°, with the temperature of the house from 5° to 10° less, will give the best practical results. With this temperature, the cut-

tings will root in about two weeks, and will be far stronger than if rooted in less time with greater heat. As soon as cuttings are rooted, they are potted off into small pots and grown in a cool greenhouse until danger of frost is over, when they are planted out in the open ground. Cuttings made too far below a joint, or too late in summer, will produce flowering plants but no tubers.

*Division of roots.*—This is the easiest and most satisfactory way for amateurs. As the eyes are not on the tubers, but on the crown to which the tubers are attached, care must be taken that each division has at least one eye, otherwise the roots will never grow. It is, therefore, best to start the eyes by placing the roots in a warm, moist place a short time before dividing. The roots are sometimes placed in a hotbed, and shoots grown to considerable size, then set out as plants; but this plan has many drawbacks, and is not advised.

*Grafting.*—A very interesting, though not profitable mode of propagation is by means of grafting. The top of the tuber is cut slantingly upward, and the cutting slantingly downward, placed together and tied with raffia or any soft, handy material. They are then planted in a pot deep enough to cover the lower part of the graft with earth, and they will soon adhere if placed under a hand-glass or in a frame. Grafting is practised only for the preservation of rare and weak-growing sorts.

*Seeds.*—The chief use of seeds is the production of new varieties. Seeds are also used by those who chiefly desire a mass of color, and are not particularly desirous of finely formed blooms. If planted early enough indoors and transplanted to the open as soon as safe, fine masses of color can be secured before frost, and the roots of the more desirable kinds can be saved, and will give even better results the next season.

#### *Field or garden requirements.*

Dahlias are easily destroyed by high winds unless they are given a protected position, and they need plenty of air and sunlight for best results. In shaded, close, airless quarters the growth is sappy, and the flowers are poorly colored.

The soil is not so important, except in its ability to hold moisture during severe droughts. Any rich soil that will grow corn will also grow dahlias to perfection, if all other conditions are favorable. They will grow equally well in clear sand, clay or gravel, if the proper kinds and quantities of plant-food are added and well and thoroughly worked in. It is, however, unreasonable to expect dahlias or any garden plants to succeed in a hard clay, devoid of humus, easily baked and never tilled.

*Feeding.*—It is always best to broadcast the manure and plow or spade it into the soil; thorough spading is absolutely necessary if the manure is not well decomposed. On heavy clay or gravelly soils, loose coarse manure may be used, but on light or sandy soils, manure should always be fine and well rotted. Commercial fertilizers are also largely used, and are most valuable when used in connection with manure. Any good fertilizer, rich in ammonia and phosphoric acid, with a liberal amount of potash, will answer at the time of planting, but as a top-dressing later, nothing equals pure bone-meal and nitrate of soda, four parts bone-meal to one part soda.

*Kinds of stock.*—Dahlias are offered in five forms: large clumps, ordinary field-roots, pot-roots, green plants and seeds. The clumps give the best satisfaction the first year, but are entirely too large and unwieldy for anything but a local trade and exchange among amateurs. The ordinary field-roots are the most valuable, as they can be handled easily and safely, and always give satisfactory results. Pot-roots are largely used in the mailing trade, and, while they will not give as good results the first year, are valuable for shipping

long distances where larger roots could not be profitably used, owing to heavy transportation charges. Green plants are mainly used to make up any deficiency in the field-crops, owing to unfavorable seasons, or an unusual demand for certain varieties.

*Planting.*—There is diversity of opinion as to the proper time to plant dahlias, but the writer has always found it best to plant early, and would advise planting large strong roots about two weeks before danger of frost is over. This would be, in the vicinity of Philadelphia, about April 15; and as it requires from two to three weeks for the plants to get up through the ground, there will be no danger, while the plants will bloom that much earlier. It is best, however, not to plant small roots or green plants until danger of frost is over—in the vicinity of Philadelphia, about May 1 to 10, according to the season. A good rule to follow everywhere would be to plant small roots and green plants as soon as danger of frost is past, and large roots about three weeks earlier.

*Tillage.*—The first requisite of successful garden cultivation is thoroughly to stir the soil to considerable depth and enrich it, if it is not already rich, by broad-casting and plowing or spading in a good coat of well-rotted manure. Too much stress cannot be placed upon the thorough preparation of the land, as it not only allows the roots to go down deep after the moisture more readily during dry weather, but affords good drainage during excessive rains. Having prepared the land as above, mark out rows 4 feet apart and 6 to 8 inches deep, and plant the roots from 18 inches to 3 feet apart in the row, according as solid rows or specimen plants are desired.

In its early stage of development, the dahlia grows very rapidly, and should be kept thoroughly tilled. But while deep tillage is beneficial during its early stages of development, it is almost fatal to the production of flowers if practised after the plants come into bloom. Therefore, when the plants begin to bloom, cease deep tillage, and stir the soil to the depth of 1 to 3 inches only, but stir it often, and never allow the surface to become hard and baked. This will not only prevent excessive evaporation of moisture and keep the under soil cool and moist, but will also prevent the destruction of immense quantities of feeding-roots.

As long as the roots supply more nourishment than is needed to support the plant, both the plant and the flowers increase in size and beauty; but as the supply gradually becomes exhausted, the plants cease growing and the flowers become much smaller. This condition is what is generally called "bloomed out," but what is really "starved out," and can easily be prevented if the proper attention is given to the plants. As soon as the flowers begin to grow smaller, broadcast around each plant a small handful of pure bone-meal, and nitrate of soda, in proportion of four parts bone to one part soda, and carefully work it into the soil.

*Watering.*—This is a debatable subject, and, although a judicious application of water during a severe dry spell is very beneficial, yet in nine cases out of every ten in which water is applied, a thorough stirring of the surface soil would give better results.

Many persons think Dahlias should be watered every evening, and as soon as they are up begin watering them daily unless it rains. This practice is very injurious, as it causes a rapid but soft growth, and as

the soil is seldom stirred, the roots become so enfeebled that they are unable to supply the needs of the plant; as a consequence, but few buds are formed, and they generally blast before developing into flowers. In other cases, as the enthusiasm wears off, watering is stopped, probably right at the beginning of a severe drought, and the weak, pampered plants are fortunate to survive, much less bloom.

If large, strong roots are planted and the soil is kept thoroughly stirred, there will be little need of artificial watering until after the plants come out in full bloom. However, if it should become hot and dry after the dahlias come into bloom, it would be very beneficial to give them a thorough watering once each week or ten days during the continuance of the drought. But care should be taken to stir the soil to the depth of 1 to 2 inches the next day, carefully pulverizing it later in order to break the natural capillarity by which the moisture is evaporated.

The best rule to follow is not to allow the plants to suffer for want of moisture, not to water them except when they need it, but to water them thoroughly when necessary, and not to allow excessive evaporation for want of frequent stirring of the soil.

*Training.*—In planting the roots or tubers, place them on their sides with the eye as near the bottom as possible, and cover only 2 to 3 inches deep. As soon as the shoots appear, remove all but the strongest one, and pinch out the center of that one as soon as two or three pairs of leaves have formed, thus forcing it to branch below the level of the ground. As the plants develop, the soil is filled in gradually by subsequent hoeings. By this method the entire strength of the root and the soil is concentrated on the one shoot, causing it to grow vigorously; while the pinching

back not only causes it to branch below the surface of the soil, and thus brace it against all storms, but also removes all of those imperfect, short-stemmed flowers that appear on some varieties. If the plants are pinched back low, as described, there is no danger of the branches splitting down, as the soil around them will hold them securely in place. However, when they branch above ground and are inclined to split down, drive a short stout stake near the stem and tie the branches to it. These short stakes are not to hold the plants up, but to prevent the branches splitting down when the above directions have not been followed closely.

By this method it is possible to grow dahlia blooms on stems from 18 inches to 2 feet long. It has always been thought necessary to tie dahlias to stakes to prevent them from being blown down by heavy winds. The system of staking is not only unsightly during the early stage of their growth, but is attended with considerable labor and expense. Staking, however, is unnecessary, if the directions already given are followed, as the plants will branch out below the surface of the ground, and the stems will become so heavy as to resist the strongest winds. The plants are one-third dwarfer, compact and regular in form, and produce much finer flowers on long stems well supplied with buds and foliage.

*Storing the roots.*—As soon as the plants are killed by frost, lift the roots, and, after removing all the soil possible from them, allow them to dry in the air for a few hours, when they should be stored in the cellar or

1215. A semi-double form of dahlia.

some other cool place secure from frost. If the cellar is very dry or is not frostproof, put the roots in a barrel or box and cover completely with dry sand or some other suitable and convenient material, such as sawdust or tanbark, to prevent freezing or loss of vitality by drying or shriveling. LAWRENCE K. PEACOCK.

**DAHOON HOLLY:** *Ilex Dahoon*.

**DÀIS** (Greek, *pine torch*; application not obvious). *Thymelæacæ*. Contains a woody plant that yields a strong fiber, and is also rarely cultivated for ornament, especially in Florida and southern California, and possibly in a few northern conservatories.

Tender deciduous shrubs: lvs. opposite, often crowded at the ends of branches: fls. in terminal heads; perianth-tube cylindrical, often curved; stamens 10, in a double series, the alternate ones shorter, upper or all exerted; style exerted. The plants are prop. with difficulty by cuttings of half-ripened wood. The single cult. species has lvs. resembling the smoke tree, or *Cotinus*, and bears long-stalked umbel-like heads of starry pink fls., with floral parts in 5's. The genus has 2 species, 1 from S. Afr. and 1 from Madagascar.

**cotinifolia**, Linn. Lvs. opposite and alternate, oblong or obovate, acute at both ends: involucre a half shorter than the fls.: head about 15-flid.; fls.  $\frac{1}{2}$  in. across, fragrant. S. Afr. B.M. 147. G.W. 8, p. 313.—Said to bloom profusely at Santa Barbara but not to produce seed.

L. H. B.

**DAISY** (i. e., *day's eye*, in allusion to the sun-like form of the flower). A name applied to the flowers of many *Compositæ*, but it properly belongs to the *Bellis perennis* of Europe, a low early-flowering plant, which, in its double forms (Fig. 535, Vol. I), is widely known as a garden subject (see *Bellis*). The American congener is *B. integrifolia*, Michx., an annual or biennial, very like the Old World species, ranging southward from Kentucky; it is not domesticated. In North America, the word daisy is applied to many field composites, particularly to those of comparatively low growth and large flower-heads. Unqualified, the word is commonly understood to mean *Chrysanthemum Leucanthemum* (Fig. 937), an Old World plant that has become an abundant field weed in the eastern part of the country.

This plant is also frequently known as the ox-eye daisy, although in parts of New England it is called whiteweed, and the term ox-eye is applied to *Rubdeckia hirta*, which has a yellow-rayed head. Kin to the *Chrysanthemum Leucanthemum* are the Paris daisies, or marguerites, of the conservatories (see *Chrysanthemum*). The wild asters (Fig. 1216) are called daisies, especially Michaelmas daisies, in many parts of the country, particularly west of New York. Spring-flowering erigerons also are called daisies. The Swan River daisy is *Brachycome iberidifolia* (Figs. 621, 622, Vol. I). The African daisy of gardens is *Dimorphotheca*.

L. H. B.

**DALBÉRGIA** (N. Dalberg, a Swedish botanist, 1730 to 1820). *Leguminosæ*. Nearly 100 species of trees, shrubs, or climbers, belonging to tropical regions all over the world, a few of which have been introduced to North America, one for timber.

Leaves alternate, odd-pinnate (rarely 1-foliate) without stipules: fls. small, numerous, purple, violet or white, in forking cymes or irregular cyme-like

panicles, which are axillary or terminal, papilionaceous, with ovate or orbicular standard: fr. an indehiscent narrow pod, 1-seeded at middle and with few seeds toward the ends, the seeds compressed and reniform.

**Sissoo**, Roxbg. A good-sized tree, 80 ft. high in India: lvs. pinnate; lfts. 5, alternate, stalked, obovate, abruptly acuminate, pubescent beneath: fls. white, in short, axillary panicles.—In India considered one of the best timbers, whenever elasticity and durability are required. Intro. at Santa Barbara, where it is hardy but growth said to be very slow. The Sissoo tree is worth trial in nearly frostless districts, especially along sandy river banks. It improves sterile lands. Experiments in Egypt have shown its most remarkable property of standing severe droughts, as well as submersion for a long period. The wood is very elastic, seasons well, does not warp or split, is easily worked, and takes a fine polish. It is also a durable wood for boats. The tree is raised easily from seeds or cuttings, and is of quick growth. Other species of *Dalbergia* are of economic value and have been sparingly planted.

**DÀLEA** (Samuel Dale, 1659–1739, English botanist and author on pharmacology). Syn. *Parosela*. *Leguminosæ*. More than 100 herbs and small shrubs bearing purple, blue, white or even yellow fls. in terminal or lateral spikes or heads, odd-pinnate lvs., and usually glandular-dotted, a very few of which have been cult.; probably none is now in the American trade. Fls. papilionaceous, the standard mostly cordate or eared and clawed and attached in the bottom of the calyx, the wings and keel attached or adnate to the stamens and usually exceeding the standard; stamens 10 or 9, monadelphous: fr. a small usually 1-seeded mostly indehiscent pod inclosed in the calyx. The species occur from the N. U. S. to Chile and the Galapagos Isls. They grow in the U. S., mostly on prairies and in dry soil; some of these species might make acceptable border plants. Those that have received most attention are tropical species, as *D. mutabilis*, Willd., of Mex., with fls. white changing to violet, (B. M. 2486) and *D. Mutisii*, Kunth (properly *Psoralea Mutisii*, HBK.), of the northern Andes, with deep blue fls. in cylindrical heads; these are to be regarded as greenhouse perennials.

L. H. B.

**DALECHÁMPIA** (from J. Dalechamps, French savant of sixteenth century). *Euphorbiacæ*. Climbing or rarely erect tropical shrubs; one rarely cultivated in warmhouses for its ornamental bracts.

Leaves alternate, simple; stipules large: fls. small, monœcious, apetalous, in dense clusters, with 2 conspicuous, colored involucre bracts; calyx valvate; styles united; ovules 1 in each of the 3–4 cells.—About 60 species scattered through the tropics. Plukenetia, a related genus, is without the large involucre.

*Dalechampia Roetziana* was described by Hooker in 1867 as one of the noblest plants introduced for many years, comparable with the bougainvilleas and surpassing them in size of bracts and brilliancy of color. It is not so fine a florists' plant as the poinsettia, but is worth trial in the finer conservatories. It requires well-drained sandy, peat soil, and is propagated by cuttings.

**Roetzliana**, Muell. Arg. (var. *rosea*, Authors). Erect shrub, 3–4 ft. high, much branched, leafy: lvs. 6 in. long, sessile, obovate-oblongeolate, acuminate, entire, or with coarse, obtuse teeth above the middle, narrowed to a small cordate base: bracts 2–2½ in. long, broadly cordate, nearly sessile, toothed, membranaceous, distinctly nerved, rose-red, other smaller bracts among the small yellow fls.; stamens united. Mex. B.M. 5640. H.F. II. 11:234, pl. 8. Gt. 16:532. F.W. 1867, p. 318. F.M. 7:373, 374. F.S. 16:1701–2. G.C. 1867:236, desc. Var. *álba*, Hort., has white bracts.

J. B. S. NORTON.

1216. Wild aster, or Michaelmas daisy. ( $\times \frac{1}{2}$ )

**DALIBÁRDA** (after Thomas François Dalibard, French botanist). *Rosaceæ*. A low-growing native hardy herbaceous perennial, with foliage resembling violet and flowers like those of a strawberry, sometimes grown in borders and rock-gardens.

This monotypic genus has lately been referred to *Rubus*, but it differs in habit, in the carpels being usually well defined instead of indefinite and the achenes dry instead of drupaceous: fls. 1 or 2 on a scape-like peduncle, white, and also others that are

cleistogamous and apetalous on short curved peduncles; calyx 5-6-parted, 3 of the parts larger; petals 5; stamens many; ovaries 5-10.

**repens**, Linn. (*Rubus Dalibarda*, Linn.). Fig. 1217. Tufted, creeping: lvs. heart-shaped, wavy-toothed: fls. white, 1 or 2 on each scape; calyx 5-6-parted, 3 of the divisions larger and toothed; petals 5; stamens numerous; pistils 5-10. Common in woods in New Brunswick, Ont. and south and west to N. J., Pa., Ohio and Minn.—It blooms June-Aug. It is a slow-growing plant, thriving in a deep fibrous soil and sheltered position; little grown. In Fig. 1217, *a* shows the perfect flower; *b*, *c*, achenes of the cleistogamous fls.

L. H. B.

**DAMASK ROSE:** *Rosa Damascena*.

**DAMASK VIOLET:** *Hesperis matronalis*.

**DAME'S ROCKET and DAME'S VIOLET:** *Hesperis matronalis*.

**DAMMÁRA:** *Agathis*.

**DAMNACÁNTHUS** (Greek, referring to the powerful spines). *Rubiaceæ*. A tender evergreen shrub, chiefly valued for its coral-red berries, which remain on the bush until the flowers of the next season are produced.

Divaricately branched, strongly spiny woody plants: lvs. small, opposite, leathery, nearly sessile, broadly ovate, acuminate: fls. small, axillary, in 1's or 2's, white, fragrant; calyx-tube obovoid, limb 4-5-cut; corolla funnel-shaped. Prop. by cuttings; sometimes grown in greenhouses and perhaps adaptable for planting in the southern parts.

**índicus**, Gaertn. Described above, being the only species as understood by some authors; but others keep *D. mājor*, Sieb. & Zucc. (which is sometimes nearly spineless), distinct, distinguishing it by the 2-3-times larger lvs. and the larger fls.; others combine the two as species and variety, as *D. índicus* var. *mājor*, Makino. Gt. 17:570. The species occurs from E. India to Japan, the var. *mājor* being Japanese. The species is a low thick bush, densely dichotomously branched: lvs. ovate-acute, shining green above, light green beneath, in var. *mājor* 1½ in. long. The shining lvs. and showy berries commend the plant to cult. L. H. B.

**DAMPING-OFF.** A gardeners' phrase for a disastrous rotting of plants, especially of seedlings and cuttings, and commonly at the surface of the ground. It is usually associated with excessive moisture in the soil and air, with high and close temperatures, and sometimes poor light. Such conditions weaken the plants and allow them to fall a prey to the minute parasitic fungi which live upon the decaying vegetable matter in the soil, and can remain alive for months, even if the soil is thoroughly dry or frozen. A whole bench of cuttings may be ruined in a night. The skilful propagator takes every possible precaution. His benches have perfect drainage, he uses fresh sharp sand, and sometimes sterilizes it with steam heat for several hours. Damping-off is one of the most trying experiences of the beginner, and nothing can prevent it but a thorough grasp of the principles of greenhouse management in general, and watering in particular. (Consult articles on these subjects.) As soon as the disease is noticed, the healthy plants should be removed to fresh soil, as the disease spreads rapidly. If the disease appears in the entire bed, the organisms causing the trouble almost certainly are distributed generally in the sand, and sterilization either with formaldehyde solution (40 per cent strength diluted one part to fifty parts water) or with steam should be employed in all future work. If only a spot here and there shows the trouble, saturate the affected area at once with formaldehyde solution, as above, or with copper-sulfate solution (one part by weight to one hundred parts of water). One of the commonest occasions of damping-off is the sudden flooding of a bed or bench after leaving it too dry for a long time.

The terms damping-off and burning are also used for ruined flowers. Burning is often caused by sunlight or by imperfections in glass, but a flower spoiled by dripping cold water, or by some unknown cause, is said to have a burned look.

D. REDDICK.†

**DAMSON:** *Plum*.

**DÀNÆ** (name of a daughter of King Acrisius of Argos). *Liliaceæ*. ALEXANDRIAN LAUREL. An evergreen erect much-branched shrub with thick unarmed alternate cladophylla and terminal racemes of small whitish fls., often referred to *Ruscus*. It is one of the *Asparagus* tribe of the lily family: fls. nearly globular, the lobes short and erect, with a crown at the throat; stamens affixed in the tube beneath the crown, the filaments united, the anthers 6: fr. a pulpy indehiscent red berry. *D. racemōsa*, Moench (*Ruscus racemōsus*, Linn. *D. Laurus*, Medikus), occurs from Greece to Persia, making a bush 4 ft. high, with ovate-lanceolate, nearly sessile, about 5-7-nerved leaf-like cladodes. Recently intro. in S. Calif., but is little known in this country. Ornamental for porches, vases, and similar uses.

L. H. B.

**DANÆA** (a personal name). *Marattiaceæ*. A small genus of tropical American fern-like plants, with synangia sessile, arranged in rows, and covering the entire under surface of the leaf. They are apparently not in cultivation in America.

**DANDELION** (i. e., *dent de lion*, French for lion's tooth; referring to the teeth on the lvs.). The vernacular of *Taraxacum officinale*, Weber, a stemless perennial or biennial plant of the *Compositæ*, a common weed, much collected in spring for "greens" and in improved forms sometimes grown for that purpose.

Dandelion is native to Europe and Asia, but is naturalized in all temperate countries. On the Rocky Mountains and in the high North are forms that are apparently indigenous. A floret from the head of a dandelion is shown in Fig. 1218. The ovary is at *e*; pappus (answering to calyx) at *a*; ray of corolla at *c*; ring of anthers at *b*; styles at *d*. The constricted part

at *e* elongates in fruit, raising the pappus on a long stalk, as shown in Fig. 1219; and thus is the balloon of the dandelion formed. A dandelion plant, with its scattering fruits, is shown in Fig. 1220. Another species of dandelion is also naturalized in this country, but is not so common; it is the red-seeded dandelion (*T. erythrospermum*, Andr.), with red fruits, not reflexed involucre scales, and shorter beak.

1218. Floret of Dandelion.

The dandelion is much prized for "greens." For this purpose it is cultivated in parts of Europe; also about Boston and in some other localities in this country. There are several improved large-leaved varieties, mostly of French origin. Some of these named forms have beautiful curled leaves. Seeds are sown in the spring, and the crop is gathered the same fall or the following spring,—usually in the spring in this country. Commonly the seeds are sown where the plants are to stand, although the plantlets may be transplanted. The plants should stand about 1 foot apart each way, and a good crop will cover the land completely when a year old. Sandy or light loamy soil is preferred. The crop is harvested and marketed like spinach. The leaves or heads are often blanched by tying them up, covering with sand or a flower-pot. The plants are sometimes grown more closely in beds, and frames are put over them to force them. Roots are sometimes removed from the field to the hotbed or house for forcing. When treated like chicory (which see), the roots will produce a winter salad very like *barbe de capucin*. Roots of dandelion dug in fall and dried are sold for medicinal purposes in drug-stores under the name of *Taraxacum*.

L. H. B.

**DANGLEBERRY:** *Gaylussacia frondosa*.

**DÁPHNE** (Greek name of *Laurus nobilis*). *Thymelæaceæ*. Ornamental woody plants, chiefly grown for their handsome foliage and sweet-scented, white, purple, lilac or rarely greenish flowers, which, with some species, in warmer climates, often appear in the winter.

Low deciduous or evergreen shrubs: lvs. alternate, rarely opposite, entire, short-petioled; fls. in clusters, short racemes or umbels, apetalous, mostly fragrant; calyx-tube cylindric or campanulate, 4-lobed, corolla-like, usually clothed with silky hairs outside; stamens 8, in two rows, included; stigma capitate, sessile or nearly so; fr. a fleshy or leathery 1-seeded drupe. —About 50 species in Eu. and Asia. For a monograph of the section *Daphnantes* see Keissler in Engler Bot. Jahrb. 25:29-124 (1898); see also Nitsche, Beiträge zur Kenntnis der Gattung Daphne (1907).

Only *D. Mezereum*, with very early lilac fragrant flowers and decorative scarlet fruit, and some low evergreen species, like *D. Cneorum* and *D. Blagayana*, are hardy North, while most of the evergreen species can be recommended only for warmer climates. *D. Genkwa* with lilac flowers appearing before the leaves, and *D. pontica* and *D. Laureola*, with large evergreen leaves, are hardy as far north as New York. *D. odora* is fairly hardy in Washington, D. C.

In California, according to Franceschi, the species most commonly grown is *D. odora*, the plants being mostly imported from Japan. Many plants are also sent from Japan for eastern greenhouse culture. A decoction

of the bark of *D. Mezereum* is sold in drug-stores under the name of *mezereum*. It is stimulant and diuretic. It is also known as olive spurge.

Daphnes thrive best in a well-drained light soil and in a partly shaded position, but some, as *D. Cneorum* and *D. Blagayana*, which are exceedingly pretty plants for rockeries, do better in sunny situations. In the North, *D. odora* and its varieties are often grown in pots for their sweet-scented and handsome flowers appearing during the winter. A sandy compost of peat and loam in equal proportions will suit them; they require a good drainage and careful watering during the winter, and pots not larger than just necessary should be given; they may also be planted out in a cool greenhouse and trained as a wall plant. *D. Genkwa*, with abundant lilac flowers before the leaves, is sometimes forced.

Propagation is by seeds, sown after maturity or stratified, but germinating very slowly; also by layers put down in spring and taken off the following year. The evergreen species may be increased by cuttings of mature wood in fall under glass, and kept in a cool greenhouse during the winter. If gentle bottom heat can be given in early spring, it will be of advantage to the development of the roots; softwood cuttings taken from forced plants may also be used. *D. odora* is often veneer-grafted on seedling stock of *D. Laureola* in winter, or on roots of *D. Mezereum*; also other species are grafted on roots of *D. Mezereum*. *D. Cneorum* and probably its allies are readily increased in spring by removing the earth around the plant, pegging down the branches and filling with fine compost almost to the tops of the branches. Next spring, if the compost is carefully removed, a large number of little buds, each supplied with a white root, are found along the branches; they are easily detached and planted in pans or boxes.

1220.  
The Dandelion.

A. *Foliage deciduous: fls. axillary along the branches of the previous year, appearing before the lvs.*

B. *Lvs. alternate, glabrous. (Mezereum.)*

1. **Mezereum**, Linn. Erect shrub, with stout branches, to 4 ft.: lvs. alternate, cuneate, oblong or oblanceolate, glabrous, grayish beneath, 1-3 in. long: fls. usually 3, sessile, silky outside, fragrant, lilac-purple, appearing long before the lvs.: fr. roundish ovoid, scarlet. Feb.-April. Eu. to Altai and Caucasus. Gn. 29:602; 33, p. 514; 69, p. 131. V. 2:206. Var. *alba*, Ait., has white fls. and yellow fr. Gn. 29:602; 69, p. 131; 74, p. 255. G.C. III. 21:183, 185; 38:153. R.H. 1905, p. 532. Var. *plena*, Schneid. (var. *alba-plena*, Hort.), has double white fls. Gn. 29:602. Var. *grandiflora*, Dipp. (var. *autumnalis*, Hort.). With larger brighter purple very early fls., sometimes blooming in fall.

2. **Houtteana**, Planch. (*D. Mezereum* var. *atropurpurea*, Dipp.). Shrub, to 4 ft., with erect, stout branches: lvs. alternate, cuneate, oblong-lanceolate, glabrous, coriaceous and often persistent, purple: fls. appearing before the lvs., lilac-violet, 2-4, in short-peduncled clusters. April. F.S. 6:592.—Of garden origin, supposed to be a hybrid between *D. Laureola* and *D. Mezereum*.

BB. *Lvs. opposite, silky below. (Genkwa.)*

3. **Genkwa**, Sieb. & Zucc. (*D. Jénkwa*, Hort.). Shrub, to 3 ft., with slender branches: lvs. opposite, oblong-elliptic, appressed-pubescent on the veins beneath,  $1\frac{1}{4}$ -2 in. long: fls. lilac, 3-7, in short-stalked clusters, scentless, densely silky-villous outside. March, April. Japan. S.Z. 75. Gt. 15:499. F.S. 3:208. G.M. 35:292. Gn. 42:91; 76, p. 105. R.B. 10:73. Var. **Fórtunei**, Franch. (*D. Fórtunei*, Lindl.), has larger fls. and larger less regularly opposite lvs.

AA. *Foliage evergreen, alternate (see also No. 2).*  
(*Daphnantes.*)

B. *Fls. in terminal heads, rarely axillary and pinkish.*

c. *Habit low, procumbent or trailing.*

4. **Cneorum**, Linn. Fig. 1221. With long, trailing, pubescent branches: lvs. crowded, cuneate, oblanceolate, mucronulate, finally glabrous, dark green and glossy above, glaucescent beneath,  $\frac{1}{2}$ -1 in. long: fls. in sessile, many-flid. heads, pink, fragrant. Apr., May, and often again in summer. Mts. of Cent. Eu. B.M. 313. L.B.C. 18:1800. Gn. 33, p. 514; 45, p. 237; 62, p. 83. G.C. III. 47:21. G.M. 47:117. M.D.G. 1900:417, 418; 1906:75. G.W. 14, p. 625. V. 2:342; 4:168. Var. **máior**, Dipp. Of more vigorous growth, with larger fls. Gn. 51, p. 358; 65, p. 457. Var. **Vérlotii**, Meissn. (*D. Vérlotii*, Gren. & Godr.). Lvs. longer, mucronate: fls. 2 weeks later than the type. R. H. 1901, pp. 304, 305; 1902:552. Var. **máximus** of European nurseries = *D. neapolitana*.

5. **Blagayana**, Freyer. Branches often ascending, glabrous: lvs. cuneate, obovate or oblong, glabrous, 1-1 $\frac{1}{2}$  in. long: heads many-flid.; fls. white or yellowish white, fragrant, nearly glabrous outside, almost 1 in. long. April, May. Mts. of S. E. Eu. B.M. 7579. F.S. 22:2313. Gt. 29:1020. Gn. 14:200; 35, p. 540; 42, p. 95; 50, p. 26; 67, pp. 287; 71, pp. 7, 247; 73, p. 241. G.C. II. 13:245; 17:505; III. 11:491; 32:300, 301; 38:171.

cc. *Habit erect, 1-4 ft. high.*

D. *Lvs. less than 2 in. long, usually pubescent: perianth densely pubescent outside.*

E. *Lobes of perianth lanceolate, acute; heads without bracts.*

6. **oleoides**, Schreb. (*D. buxifolia*, Vahl). Shrub, to 3 ft.: branches pubescent: lvs. obovate-elliptic to obovate-lanceolate, usually mucronulate or acute, villous-pubescent on both sides or finally glabrous above, punctulate with whitish dots, 1-1 $\frac{1}{2}$  in. long: fls. in few-flid. heads without bracts, white or pale lilac, with

ovate-lanceolate, pointed lobes,  $\frac{1}{2}$  in. long. S. E. Eu. L.B.C. 3:299. B.M. 1917.—Very variable in shape and pubescence of lvs. Var. **Fioniàna**, Hort., with obovate-lanceolate, obtuse lvs. and lilac fls., is said to be a hybrid between this species and *D. collina*.

EE. *Lobes of perianth ovate, obtusish; heads with bracts at the base.*

7. **collina**, Smith (*D. australis*, Cyrill. *D. sericea*, Hort., not Vahl). Shrub, 1-3 ft.: branchlets villous: lvs. scattered, oblong-ovate to oblanceolate, obtusish, glabrous and shining above, tomentose below, 1-1 $\frac{3}{4}$  in. long: fls. rosy purple, fragrant,  $\frac{3}{4}$  in. long, in 10-15-flid. heads, lobes broad-ovate, obtuse, about as long as tube; bracts broadly oval, tomentose, about half as long as the fls., persistent for some time. April-June. Italy, Crete, Asia Minor. B.M. 428. B.R. 24:56. Var. **neapolitana**, Lindl. (*D. neapolitana*, Lodd. *D. Delahayana*, Hort.). Lvs. glabrous or nearly so. L.B. C. 8:719. B.R. 822. By some supposed to be a hybrid of *D. collina* and *D. Cneorum*.

8. **sericea**, Vahl (*D. oleifolia*, Lam.). Shrub, 1-2 ft.: branchlets short, puberulous or nearly glabrous: lvs. crowded at the end of the branchlets, lanceolate or oblanceolate, acute or acuminate, glabrous above, appressed pubescent beneath, sometimes nearly glabrous,  $\frac{1}{2}$ - $\frac{3}{4}$  in. long: fls. in 3-8-flid. heads, rose-colored,  $\frac{3}{4}$  in. long, lobes broadly ovate, obtuse, a third shorter than tube: bracts obovate, silky, soon drooping. May, June. Sicily, Crete, Asia Minor. Ann. Mus. Hist. Nat. Paris 10: 20.—Rare in cult.; usually confused with the preceding species.

DD. *Lvs. usually longer than 2 in., glabrous (or slightly pubescent beneath in No. 9); perianth glabrous or pubescent.*

E. *Apex of lvs. obtuse or acutish.*

F. *Heads of fls. all terminal, usually many-flid.; bracts persistent.*

1221. *Daphne Cneorum*.

9. **hýbrida**, Lindl. (*D. Dauphinii*, Hort. *D. Delphinii*, Lodd.). Garden hybrid of *D. collina*  $\times$  *D. odora*. Similar to *D. odora*, but hardier. Erect shrub, to 4 ft.: lvs. cuneate, oblong-elliptic, dark green and shining above, glabrous or slightly hairy along the veins beneath when young, 2-3 in. long: fls. reddish purple, pubescent outside, very fragrant, rather large, in few-flid. heads. B.R. 1177.

10. **odora**, Thunbg. (*D. sinensis*, Lam. *D. indica*, Loisel., not Linn.). Shrub, to 4 ft., with glabrous branches: lvs. oblong-elliptic, acute at both ends, bluntly pointed, glabrous, 2-3 in. long: fls. in dense, terminal heads, very fragrant, white to purple; ovary glabrous; bracts 6-10, lanceolate, persistent. Winter and spring. China, Japan. Gn. 28:8. J.H. III. 50:367. V. 4:318. Gng. 2:211. Var. *alba*, Hemsl. Fls. white. Gn. 28:8; 37, p. 10; 76, p. 240. G. 8:45; 22:9. Var. *punctata*, Hemsl. Fls. in dense heads, white, spotted outside with red. B.M. 1587. Var. *marginata*, Hort. Lvs. bordered yellow: fls. red. P.M. 8:175 and R.H. 1866:252 (as *D. japonica*). A.G. 22:843. Var. *rúbra*, Sweet. Fls. purple. S.B.F.G. II. 4:320. G.C. III. 21:173.—By some botanists *D. odora* and *D. sinensis*, Lam. (*D. indica*, Loisel.), are considered distinct species: *D. odora* has larger fls. about  $\frac{3}{4}$  in. long, glabrous outside, the bracts shorter than the fls., and

usually oval lvs., while *D. sinensis* has fls. about  $\frac{1}{2}$  in. long, slightly silky outside, the bracts longer than the fls., and usually oblong-elliptic lvs.; but it is doubtful whether these characters are constant.—*D. odorata*, Hort., is a common misprint in catalogues for *D. odora*. *D. odorata*, Lam. = *D. Cneorum*.

FF. Heads of fls. axillary and terminal, few-fl'd.; bracts caducous; perianth glabrous.

11. *japónica*, Sieb. & Zucc. (*D. Mazéliei*, Carr.). Shrub, to 4 ft.: branches glabrous: lvs. oblong-deltoid, gradually narrowed at the base, nearly sessile, 2–4 in. long: heads axillary and terminal short-peduncled, 3–4 fl'd.; fls. pink, short-pedicelled,  $\frac{1}{2}$  in. long; lobes ovate, obtuse, as long as tube; bracts ovate-lanceolate, ciliate, slightly shorter than fls.; peduncles and pedicels silky. Spring. Japan, China. Gn. 14:442.

EE. Apex of lvs. usually emarginate.

12. *retusa*, Hemsl. Shrub, 2–3 ft.: branchlets pubescent at first, soon glabrous: lvs. oblong or oblanceolate-oblong, obtuse and usually emarginate, narrowed at the base into a short petiole, glabrous, 1–3 in. long,  $\frac{1}{2}$ – $\frac{3}{4}$  in. wide: fls. white, tinged outside rose or violet, glabrous, fragrant,  $\frac{3}{4}$  in. long, in many-fl'd. terminal heads; lobes slightly shorter than tube; bracts 3–4, oval or obovate, ciliate, deciduous, shorter than fls.: fr. red. May. W. China. B.M. 8430.—Recently intro. and apparently fairly hardy; a very desirable plant.

BB. Fls. axillary, yellowish or greenish white, glabrous outside.

13. *Laurèola*, Linn. Shrub, to 4 ft.: lvs. cuneate, obovate-lanceolate, acute, shining and dark green above, glabrous, 2–3½ in. long: fls. in 5–10-fl'd., nearly sessile racemes, yellowish green, scentless: fr. black. March-May. S. Eu., W. Asia. Gn. 29, p. 602 (poor). Var. *Philippii*, Arb. Kew (*D. Philippii*, Gren. & Godr.). Lower: lvs. obovate: fls. often violet outside; bracts as long or longer than the fls. Pyrenees.—Var. *purpurea* of the Kew Arboretum = *D. Houtteana*.

14. *póntica*, Linn. Shrub, to 5 ft.: lvs. cuneate, obovate or obovate-lanceolate, acute, shining, glabrous, 2–3 in. long: fls. in long-peduncled, 1–3-fl'd. clusters, greenish yellow, fragrant, with linear-lanceolate lobes. April, May. S. E. Eu., W. Asia. B.M. 1282. G.C. II. 14:209. G.W. 5, p. 261.

*D. alpina*, Linn. Erect shrub, to 2 ft.: lvs. deciduous, cuneate-lanceolate, sparingly silky: fls. white or blushed, terminal, fragrant. May, June. S. Eu. L.B.C. 1:66. Gn. 29, p. 603.—*D. altaica*, Pall. Shrub, to 4 ft.: lvs. deciduous, cuneate, oblong-lanceolate, glabrous: fls. white, in terminal, 1–5-fl'd. heads, fragrant. May, June. Altai, Sogaria, Mongolia. B.M. 1875. L.B.C. 4:399.—*D. arbuscula*, Celak. Evergreen dwarf shrub: branchlets red: lvs. crowded at end of branchlets, linear-oblong-lanceolate, obtuse, pubescent or glabrous beneath,  $\frac{3}{4}$  in. long: fls. pink, in 3–8-fl'd. heads. June. Hungary.—*D. caucásica*, Pall. Allied to *D. altaica*. Lvs. narrower: fls. in 3–20-fl'd. heads. Caucasus. B.M. 7388.—*D. glomerata*, Lam. Allied to *D. pontica*. Low: fls. light pink, fragrant, the clusters crowded at the ends of the branches. May. W. Asia.—*D. Gnidium*, Linn. Evergreen shrub, to 2 ft.: lvs. linear-lanceolate, acute, glabrous: fls. yellowish white, fragrant, in terminal racemes or panicles. S. Eu. L.B.C. 2:150. Gn. 29, p. 603.—*D. jezoensis*, Maxim. Upright shrub, 2 ft.: lvs. oblong-obovate, persistent, obtuse,  $1\frac{1}{2}$ –3 in. long: fls. axillary, yellow. March, Apr. Gt. 15:496.—*D. kamschática*, Maxim. Low upright shrub, sparsely branched: lvs. oblong-lanceolate, acutish: fls. fascicled, yellowish. Kamchatka, Manchuria.—*D. papyrifera*, Sieb. = Edgeworthia papyrifera.—*D. petraea*, Leyb. Dwarf evergreen shrub: lvs. linear-lanceolate, small, obtuse: fls. light pink, in terminal, 3–6-fl'd. heads, fragrant. June, July. S. Tyrol. Gn. 69, p. 327.—*D. pseudo-mezereum*, Gray. Low, almost decumbent shrub: lvs. lanceolate-oblong, acutish: fls. fascicled, axillary, greenish yellow, scentless. March, Apr. Japan.—*D. rupéstris*, Fach. = *D. petraea*.—*D. salicifolia*, Lam. = *D. caucásica*.—*D. Sophia*, Kalen. Allied to *D. caucásica*: lvs. obovate-oblong, glaucous below: heads few-fl'd. S. Russia.—*D. striata*, Tratt. Dwarf evergreen shrub: lvs. small, cuneate, linear-lanceolate, glabrous: fls. in terminal, many-fl'd. heads, pink. June, July. Switzerland and Carpathian Mts.—*D. Vahlia*, Keissler. Allied to *D. collina*. Branchlets thick, puberulous: lvs. obovate or oblong-obovate, appressed-pubescent below: heads 8–10-fl'd.: bracts obovate, silky, deciduous. Crete, Asia Minor.—*D. jezoensis*, Hort. = *D. jezoensis*.

ALFRED REHDER.

DAPHNÍDIUM: *Benzoin*.

**DAPHNIPHYLLUM** (Greek, *laurel leaf*, from the similarity of the leaves). *Euphorbiaceæ*. Broad-leaved evergreen hardy or semi-tropical shrubs or small trees, sometimes cultivated for their handsome large foliage.

Leaves large, without stipules, leathery, smooth, more or less glaucous, alternate, entire, petioled, pinnately veined: fls. dioecious, in axillary racemes or panicles, apetalous; calyx 3–8-parted, small, imbricate; stamens 5–18; pistil 2-celled, 4-ovuled: fr. a small, olive-like drupe, usually 1-seeded.—Twelve to 20 species, mostly in Trop. Asia, etc. The one, or possibly two, species, rarely seen in cult. in Amer., are from Japan. The large evergreen lvs. distinguish it from other hardy euphorbiaceous shrubs. They are somewhat rhododendron- or laurel-like, hardy as far north as the Middle Atlantic States, and make very handsome broad-spreading shrubs with inconspicuous fls.

*Daphniphyllum* can be propagated by cuttings, but roots rather slowly, and if seed could be secured it would no doubt give better results. The plants need protection from frost in winter till well established. They are strong growers in rich soil.

*macrodonum*, Miq. (*D. glaucescens*, Hort.). A shrub or small tree, broad and compact, 5–10 ft. high, or more in native land, smooth, twigs red: lvs. oblong, 2 x 8 in., bluish glaucous below; petiole 1–2 in. long, red; lateral veins,  $\frac{3}{8}$ – $\frac{1}{2}$  in. apart: fls. small, in short racemes: fr. oblong, not over  $\frac{1}{2}$  in., black. Japan and China. G. 18:478; 31:16. S.I.F. 1:54.

Two other names, *D. glaucescens*, Blume, and *D. jezoense*, Hort., occur occasionally in horticultural literature. The first has scarcely glaucous lvs. with lateral veins  $\frac{1}{2}$ – $\frac{1}{2}$  in. apart and is probably not in cult.; the latter is a more dwarf form than the others.

J. B. S. NORTON.

DÁRBYA: *Nestronia*.

**DARLINGTONIA** (after William Darlington, of West Chester, Pa., author of "Memorials of John Bartram and Humphrey Marshall," and of "Florula Cestrica.") *Sarraceniacæ*. A monotypic genus of American pitcher-plants which, apart from their striking aspect and beautiful coloring, have acquired celebrity from their insectivorous habits.

The short rhizomes grow in fine muddy soil, and produce annually a terminal rosette of lvs., all of which are modified into upright pitchers: each pitched lf. is 3–30 in. long by  $\frac{1}{2}$ –3 in. wide, is somewhat spirally twisted, hollow throughout and with a median crest or flap in front; the tube represents the hollowed lf.-midrib, the flap is formed by the fused halves of the lf. that have united by their upper faces in front of the midrib; the top part of the tube curves over in rounded fashion to form a down-directed pitcher orifice, from which depends a bilobed unusually crimson and green appendage of attractive aspect; the rounded top is also beautifully mottled by white translucent areas; the pitcher exterior and the appendage bear many honey-glands, the excretion from which tempts insects toward the orifice. The rounded hood is lighted within through the white areas, and bears many attractive honey-glands interspersed with down-directed hairs. Tempted by the former, and impelled by the latter, insects step or drop on to the upper interior of the tube. This is extremely smooth, affords no foothold, and so they soon tumble into the lower part. This is covered by down-directed hairs which prevent egress of the caught prey. Disintegration of the insects, amid a neutral liquid that is excreted by the pitcher-wall, then takes place and the products are gradually absorbed through thin areas of the lower cavity. Honey-secretion and insect-catching proceed most actively in May and June; by midsummer, therefore, each pitcher is filled to a depth of 4–8 in. by a decaying mass of insect-remains, amid which at times centipedes or a slug may be found. The genus is native from N. Cen. Calif. to S. Ore. It occurs there on the Sierras by the edge of mountain swamps or "deer-licks" at an elevation of 2,000–8,000

ft. Specimens were first hurriedly collected by W. D. Brackenridge of the Wilkes Exploring Expedition, on the southern slopes of Mt. Shasta, when the explorers were retreating before attacking Indians. The specimens were described and named by Torrey.

Darlingtonias have been grown outdoors in the East the year round in a few special localities. Edward Gillett at Southwick, Massachusetts, grows them in a favored spot without artificial protection. F. H. Horsford can preserve them at Charlotte, Vermont, with the aid of a winter mulch.

As greenhouse plants, darlingtonias require the same treatment as their allies, *sarracenias*, *dioneas* and *droseras*. A well-grown collection of these plants is not only very interesting and curious, but also very beautiful. To succeed, they must occupy a shaded position, and never be allowed to become dry. Give a cool, moist, even temperature. If possible, a glass case should be provided for them, with provision made for ventilation; a constant moist atmosphere can be more easily maintained, and at the same time the greenhouse in which they are grown may be freely ven-

1222. Young plant of *Darlingtonia*.

tilated without injury to these plants. The material in which they grow best is two-thirds fern-root fiber with the dust shaken out, and one-third chopped sphagnum moss and silver sand, with a few nodules of charcoal added. About the first week in July is perhaps the best time for potting, though one must be guided by the condition of the plants, choosing a time when they are the least active. When well established they will require potting only once in two years. The pots should be placed in pot-saucers as a safeguard against their ever becoming dry, and all the space between the pots should be filled with sphagnum moss up to the rims of the pots. A temperature of 40° to 45° during winter, with a gradual rise as the days lengthen in spring, will suit them admirably. During the summer they should be kept well shaded, or they may be removed to a well-shaded frame outside in some secluded position free from hot drying winds. Propagation of these plants is effected by division of the roots, or by seeds sown on live sphagnum moss in pans, the moss being made very even and the pans placed either under a bell-jar or glass case in a cool moist atmosphere. (Edward J. Canning.)

*californica*, Torr. Fig. 1222. Rootstock horizontal: lvs. 5-8 in annual rosettes, long-tubular, somewhat twisted, with median anterior flap, green below, green mottled with white over the arched hood, orifice down-directed with bilobed red and green appendage in front: fl.-stalk 10-30 in., bearing scattered bracts; fl. solitary, inverted; sepals 5, pale green; petals 5, yellowish to brown-red with red veins; stamens 15-12, inserted below ovary; ovary obconic with depressed apex, style 5-lobed with radial stigmas; caps. obovate, surrounded by the persistent sepals. Flowers from May to July, according to elevation. B.H. 5:113. F.S. 14:1440. F.M. 1869:457. B.M. 5920. I.H. 18:75. G.C. III. 7:84; 17:304; 24:339.—Intro. into cult. in 1861. Var. *rùbra*, Hort. Differs from type in being a reddish hue.

*D. Courtii* = *Sarracenia Courtii*.

J. M. MACFARLANE.

DARNEL: *Lolium perenne*.

**DARWÍNIA** (Dr. Erasmus Darwin, an English nature-student). *Myrtaceæ*. About 40 Australian evergreen shrubs, a very few of which are sometimes grown for the colored flower-like campanulate involucres that hold their condition 3-5 months; not in the American trade. Lvs. few and usually heath-like: fls. small, inclosed in petal-like bracts at the summit of the branches; calyx-lobes 5; petals 5; stamens 10, alternating with staminodia; ovary 1-celled, the fr. 1-seeded. The darwinias prop. from well-ripened tips of side shoots taken in early autumn or in spring. They require greenhouse or intermediate temperatures. *D. Hookeriàna*, Benth. (*Genetyllis fuchsioïdes*, Hort.). Lvs. linear-oblong, ½ in. long, scattered: sts. red: inner bracts of hanging involucre 1 in. long, bright red, the outer ones shorter and greenish and passing into the st.-lvs.: fls. small, greenish white, usually about 6 in each involucre. B.M. 4860 (as *Genetyllis macrostegia*). G.C. III. 43:243. F.S. 10; 1009. *D. macrostègia*, Benth. Lvs. elliptic-oblong, ¾ in. or less long, scattered: inner bracts 1½ in. long, creamy white with red splashes and stripes, the outer ones shorter and more colored, the lowest ones passing into the foliage. B.M. 4858 (as *Genetyllis tulipifera*). I.H. 2:73. F.S. 10:1064.

L. H. B.

**DASHEEN**. Edible crown-tubers of *Colocasia*, lately cult. in the U. S. to some extent. See p. 830; also *Taro*.

**DASYLÍRION** (Greek, *tufted lily*). *Liliacæ*. Stiff short-trunked desert plants, with crowded leaves and elevated panicles of small mostly white or whitish flowers.

Caudex or trunk erect and woody: lvs. numerous, near the top of the trunk, long and rigid, usually prickly-margined: fls. dioecious, in dense racemes which are crowded into a narrow compound panicle; perianth campanulate, the segms. toothed, distinct and nearly equal, obtuse; stamens 6, exserted, style short; stigmas 3: fr. dry and indehiscent, 3-winged, 1-celled and 1-seeded.—About 15 species. Mex., to Texas and Ariz. Monograph in Proc. Amer. Phil. Soc. 50, p. 404 (1911).

Dasyilirions are highly ornamental plants, well adapted for rockeries, for isolated specimens on lawns, decoration of conservatories, staircases and similar uses, and eminently suitable for terraces and vases, in the formal style of gardening. The leaves are in large number, inserted in a symmetrical way, so as to form a dome or globe-shaped, regular head, more or less serrulated, and in some species ending in a brush-like tuft of dried fibers. The tall panicles of numberless whitish green minute flowers are also a striking feature, standing far above the crest or crown of leaves. They are of the easiest possible culture, and will stand some degrees of frost, particularly if kept dry. Easily propagated from seeds and from cuttings of the branches when produced, as they do not sucker as a rule. These plants are inferior to *Yucca filamentosa*

in hardness, showiness and regularity of flowering, but they have an individuality of their own. They are especially esteemed in California, where the great flower-stalks, 8 to 10 feet high, give a strong impression of the desert. The individual flowers are not highly colored, but the spikes are several feet long. These and related plants have been the subject of recent revision. *Beaucarnea* is now considered to be distinct, and a new genus, *Calibanus*, is erected by Rose on *D. cespitosum*. These new treatments are explained under *Nolina*.

A. *Lvs. flat, prickly-margined.*

B. *Lvs. usually green, splitting into fibers at tip, narrow.*

**texanum**, Scheele. *Lvs.*  $\frac{1}{2}$  in. x 2-3 ft., glossy green: prickles yellow, turning brown: infl. 9-15 ft. high: fr. elliptical,  $\frac{3}{16}$  x  $\frac{1}{16}$  in., shallow-notched. S. Cent. Texas.

**acrótriche**, Zucc. (*D. acrótrichum*, Baker. *D. grácilis*, Planch. *Bonapártea grácilis*, Otto. *Roulinia grácilis*, Brongn. *Yucca grácilis*, Otto. *Y. acrótricha*, Schiede. *Barbacenia grácilis*, Brongn. *Littæa grácilis*, Hort.). *Lvs.* very narrow,  $\frac{3}{8}$  in. x 2-3 ft., sometimes dull or pale: prickles pale yellow, brown at tip: infl. 9-15 ft. high: fr. round-cordate,  $\frac{3}{16}$  x  $\frac{1}{4}$  in., shallow-notched. WILLIAM TRELEASE.†

**DATE.** A palm, *Phoenix dactylifera*, Linn., native to North Africa or Arabia and extensively planted in countries inhabited by Arabs, and having arid or desert conditions. Figs. 1223-1226. It is also grown to some extent in southern Asia and southern Europe and in other tropical and subtropical countries. It is of very ancient cultivation, having been grown along the Tigris and Euphrates Rivers for four thousand years or more. It has long been planted casually in parts of Mexico and the southwestern parts of the United

States, and is now becoming a fruit of commercial promise in some of these regions.

The date palm reaches a height of 100 feet, making a nearly straight, shaggy trunk, and it continues to bear for one or two centuries. It is dioecious, the males usually equaling the females in a batch of seedlings, this constituting one of the great disadvantages of raising seedling dates. The Arabs practise artificial pollination by tying male flowers on the pistillate clusters. The flowers are produced early in the spring, from six to twenty clusters appearing on a mature tree. The female or fertile clusters of good size will produce as much as twenty to forty pounds of dates. As with apples and other fruits, there are many varieties differing in quality; seedlings do not reproduce the variety, so that propagation of named varieties must be accomplished by other means.

The date is the fruit, being essentially a drupe, measuring 1 to 3 inches long. The date of commerce is the cured and dried natural fruit. The sweet nutritious pulp of the fruit constitutes one of the most important foods of the Arabs. The leaves and other parts of the plant afford materials for dwellings and many domestic uses. The wood or trunk is used for timber. The importation of dates into the United States amounts to about \$500,000 worth annually. No doubt the consumption will be greatly increased when a home-grown and clean-packed product is obtainable.

Aside from the direct uses of the plants and the fruits, the date palm is valuable as a cover for other crops in the hot and dry regions. Beneath the palms, other fruits, vegetables and many crops may be grown with more safety than in the open blazing sun. It is probable, therefore, that the date palm will become a feature of the farming in all the regions of the Southwest in which it thrives.

#### The general situation.

In Florida, California, and restricted areas of a few other states, the date has been grown for decorative purposes for more than a century. At the missions founded by the Spaniards at St. Augustine, and other places in Florida, and that long line of missions extending from far into Mexico northward and westward through southern New Mexico, Arizona and California, it is likely the date was planted wherever the climatic conditions were favorable to its growth. Within the borders of the United States the greater number of these early plantings were in Florida or along the coast of southern California, regions where the sum total of summer heat is not sufficient to develop the date fruit perfectly. The date, as a fruit-producer, being indigenous to a desert environment, does not take kindly to humid regions, even where it is not sufficiently cold to prohibit the growth of the tree. It is not only a question of maturing the tree or even of producing the fruit but also of bringing the fruit to perfect ripeness. For this reason the greater number of the early plantings in this country matured little fruit, while that produced was of poor quality, although in many instances the trees grew luxuriantly and to large size. In the more arid parts of Lower California and Sonora, where there is sufficient water for irrigation, the early plantings have been continued down to the present time, and dates of fair quality have been grown for many years. Moreover, each year the area devoted to dates is increasing, and with the recent studies of the life-history of the plant by Swingle and others the adaptation of regions is now better understood and undoubtedly the future plantings will be made with much better assurance of success. Modern date culture in this country may be said to have begun with the planting of imported Egyptian and Algerian palms and seedlings principally in Salt River Valley, Arizona, in the years 1890-1900. Toumey's studies of these early plantings resulted in Bulletin No. 29 of the

Arizona Station. Studies of conditions in the Saharan region and the importation of varieties by the United States Department of Agriculture, were made in 1899 and 1900. These results were set forth in Bulletin No. 53 of the Bureau of Plant Industry, by Swingle. Stations for testing the introductions were provided by Arizona in 1899, by California in 1904, and by Texas in 1907. Subsequent large importations were made by Fairchild and Kearney, as described in Bulletins Nos. 54 and 92 of the Bureau of Plant Industry of the national Department of Agriculture.

Dates unquestionably can be grown profitably in many of the hot dry irrigated valleys in the southwestern parts of the United States. The Salton Basin in southern California promises particularly well for date-culture because of the high temperature, and here even the famous Deglet Noor date of the Sahara will ripen fully, even in cool seasons. Considerable attention is also being given to dates in the newly developing Imperial Valley. In northern California, the date can undoubtedly be grown for home use in many regions, even north of San Francisco; it finds good conditions for commercial culture in parts of Arizona; and there are probably adaptable regions in Texas. The date can endure more alkali than any other profitable fruit crop, and this fact will extend the range of its usefulness. When once well established, brief temperatures as low as 10° F. do not do serious harm to date palms.

While date trees have been grown in the United States and Mexico for certainly more than a century, and while much fruit has been produced incidentally here and there, largely as a by-product, nevertheless date-growing on a commercial scale is yet a new and experimental industry in this country. Although it promises well, the business requires experience and skill, and it must be established only in those regions which are particularly adapted to it, especially those that have an extremely hot summer climate. As yet, the returns from date-culture are almost impossible of determination. As nearly always happens with new and promising industries, doubtful claims have been made for profits of date-culture by interested parties. It must be borne in mind that practically all the varieties now recommended for commercial cultivation in this country are of Old World origin. Although many seedlings are being raised, it is yet too early to designate any one of them as superior for general orchard planting. It is advisable that in the regions in California and Arizona, and elsewhere, that are adapted to dates, numbers of seedlings should be raised from the best varieties, care being taken that they have been pollinated from the best males; in this way the chance will be increased of originating varieties that are especially adapted to the region. The business must be developed by residents and those who study the conditions closely from year to year.

According to Swingle, at present less than a dozen varieties among the 200 or more on trial at the government date-gardens in the Southwest can be said to be well enough known to warrant planting on a commercial scale. The Deglet Noor and the Tazizaoot can be recommended for orchard planting in the Coachella and Imperial Valleys of California; the Halawy, the Khadrawy, the Maktoom, and the Hayany are promising for cooler regions, such as the Salt River Valley of Arizona, and may be planted in the California date regions on a scale not too large for the early markets; the Rhars is excellent for home use as a fresh date, but is of little commercial value; the Theory is a dry date of great promise, but it is as yet doubtful whether dry dates can be marketed advantageously on a large scale without an expensive publicity campaign. To plant other varieties that are new or inadequately tested, involves a considerable element of risk. The fact that they appear satisfactory in the Old World

deserts is no guarantee that they will grow, bear, and ripen fruit properly in the Southwest or that their fruit will prove acceptable to American buyers. Any planting of a variety on a large scale before it has been thoroughly tested must be considered as a speculation. It would be much safer for those who expect to grow dates on a commercial scale to limit themselves at first to those varieties that have been tested by public and private agencies, and to learn all phases of the culture, curing, packing, and marketing of the fruit of one or more of the standard varieties. This is the best possible preparation for the efficient culture of new sorts when they have been sufficiently tested in the government or other adequately supervised testing-gardens to render it desirable to test them on a commercial scale

1223. Young date palm, with growing suckers or offshoots.

in private culture. The government, through the Department of Agriculture, has taken special pains to safeguard the young industry.

#### *Propagation.*

It is always preferable to propagate dates from suckers unless one desires to originate new varieties, not only on account of the knowledge of the sex (it being hardly necessary to state that the sex of a sucker is the same as that of the plant from which it is taken), but on account of the ability to make a selection in the variety and quality of the fruit.

Dates are easily grown from seed if the ovules have been properly pollinated. Seeds may be planted in any month immediately after they are taken from the fruit, particularly in the mild climates of the Salton Basin, Lower Colorado Valley, and Salt River Valley. Unless the conditions are good, however, it is better to stratify them in a box between layers of moist sand and allow them to remain for three to six weeks in order that the seed-coats may be softened. It is important, however, that in the stratifying-box the seeds do not sprout, as they are easily damaged after sprouting takes place. The seed may be sown in nursery rows and the young seedlings transplanted after one, two or three years; or if the field is well prepared, and has good irrigation, the seed may be planted directly in the fields where the palms are permanently to remain. If they are placed directly in the field, it is well to plant them in rows 25 to 30 feet apart and to allow the young plants to stand

3 to 5 or 6 feet apart in the row. When the dates come into bearing, the undersirable ones and the males may be removed and the probability is that a sufficient number of good varieties will remain to make the row properly continuous; and the rows will be far enough apart for the regular or permanent plantation.

Suckers or offshoots are taken from the base of the young palm (Figs. 1223, 1224). One to several suckers may be removed each year, averaging two to four for the productive period, and when they are three to six years old and have begun to develop roots of their own. All species belonging to the genus *Phoenix* are difficult to transplant with uniform success. Frequently as high as 50 per cent of transplanted dates die even when watered daily and given the best of care. In planting suckers with the best of attention, a percentage die; while without care not one in a hundred will grow. It is due not so much to the lack of experience in removing the suckers as to lack of proper care after removal, that so large a percentage fail.

Suckers may be removed at any time during the spring or early summer, or even in the winter, if proper care be given them after removal. If they are to be planted in the open ground it is advisable to remove them in spring or early summer, April probably being the best month. In winter, when the plants are at a standstill, the suckers may be removed with comparatively small loss, if the "bulbs" or bottoms be not less than 4 inches in diameter. It is necessary, when suckers are removed at this season, to set them in rather small pots, so that the earth, which should be given a daily soaking, may have a chance to get warm quickly. The pots should be kept in a dry greenhouse, or, better yet, imbedded in a hotbed of manure, covered with the customary frame and glass. In all cases the leaves should be cut back to 6 to 12 inches in length, and sometimes they are removed. Transplant only when the ground is warm.

If proper attention can be given it is best to plant large suckers where they are to remain, as a second chance for loss occurs when they are transplanted from a nursery to the position that they are finally to occupy. An iron bar weighing thirty to forty pounds, and flattened to a 4-6-inch cutting end, may be used to cleave the offshoots from the tree. The leaf-stalks should be cut away, exposing the bulb of the sucker, care being taken not to injure the bulb in removing. One should cut in rather deeply at either side, not being afraid of injuring the old plant, cutting out a V-shaped portion extending from the base of the bulb downward for a few inches. Wounds may be painted with coal-

tar to prevent bleeding and evaporation. It is important, when planting the suckers in the field, to set them so high that the crown-bud will not be covered with water during irrigation, in order to avoid decay and death.

A successful method of rooting the suckers is to bank up earth about the base of the parent tree and above the base of the suckers, and keep moist by watering daily to induce formation of roots. Suckers may be partially severed from the old stock before the banking is done, or after the roots have started. When the roots are well grown, the suckers may be transplanted with little loss.

The suckers will grow perfectly well, however, if no roots are left attached. The offshoots may be cut away from the parent plant, with all the leaves removed, and leaving only the bud in the center or at the apex surrounded by the leaf-stalks. Such offshoots will stand very much exposure and may be shipped long distances without being packed in moist material, care being taken that the boxes are so filled with packing that they will not be jammed or bruised in transportation. After they are planted, they should be kept constantly moist about the bottom and should not be allowed to suffer any check. The Arabs apply water every day for thirty or forty days and then continue to irrigate each week until the following winter, care being taken not to water too much. If these precautions are taken and if the offshoots are planted in warm ground, there need be very little loss. They should never be set in the open ground when the soil is cold, as in fall or winter. If the offshoots are to be taken off at that time, they must be grown in pots or in some similar way, as described above.

1224. Deglet Noor date palm about eight years old, with offshoots and ripe fruit.

#### *The growing of dates.*

The date palm grows in nearly all kinds of soil, if only the climatic conditions are right. If it be sufficiently irrigated and have the requisite amount of heat, the soil seems to be a secondary consideration. In general it may be said, however, that sandy-loam soils of the desert, with a small percentage of clay and slightly charged with salts, are preferable to rich and heavy soils, suitable for growing ordinary crops. The question of water is of great importance in the culture of dates, as it is necessary that the roots of the date palm be in moist earth throughout the year. In general, the amount of water required for successful culture is considerable. If sufficient water cannot be supplied by natural methods, one must resort to irrigation. Water should be supplied at frequent intervals throughout the year. However, the most should be supplied in the spring before blooming, and in the fall prior to the ripening of

the fruit. The amount of water for each palm depends so much upon soil and local conditions that an estimate would be worthless. Care should be taken not to irrigate to excess at the time of blooming and immediately after, as it will militate against the successful setting of the

1225. An American seedling date.

fruit. The date seems to enjoy not only a high-atmospheric temperature, but a high temperature of the water supplied in irrigation as well. In irrigating small crops by flooding, it is necessary in midsummer to irrigate late in the afternoon or at night in order to prevent scalding. Care should be taken, in the hotter part of the year, that the date palm is not subjected to hot water about the roots, rising above the soil for a considerable length of time, and later left until the soil becomes exceedingly dry and baked by the sun. Such extremes sometimes seriously injure or destroy the tree.

The date palm comes into bearing early, examples being known in California of fruits being produced two years after the seeds were planted. It usually requires six to eight years, however, for seedlings to bear any

considerable quantity of dates. Under the best date-culture, seedlings are not used but the plants are propagated by means of suckers, as already explained; these suckers soon become established and will bear abundantly in five or six years afterwards. After ten or fifteen years, the palm may be considered to be in full bearing and should continue to produce indefinitely. It should yield 100 to 200 pounds of fruit annually, although there are cases of very much higher yields than this. To conserve the strength of the parent plant, the suckers should not be allowed to grow around the base in large numbers. Usually not more than three or four of these suckers or offshoots are allowed to remain at any one time. After the palm is in full bearing and has a trunk a few feet high, the offshoots cease to be produced. It is recommended, however, that one offshoot be left attached to the mother plant in order to replace the tree in case of an accident. If the date palm is allowed to grow as it will, it becomes a clump of many trunks, surrounded by a jungle of offshoots.

It is advised that the date palm be planted at distances of not less than 26 to 33 feet. Other crops can be grown between the trees till they come into bearing heavily, or even continuously.

Under proper cultivation, the date palm should produce from ten to fourteen leaves each year. A well-developed tree will have at one time from thirty to sixty leaves, the old ones dying away below while new ones are forming at the top. The different varieties show great variation in rapidity of growth, form and length of leaves, size of stem, and general aspect of plant. The stem of the date palm is very rigid. When the stem reaches a height of 5 or more feet it is frequently necessary to tie the growing bunches of dates securely to the lower leaf-stalks, that they be not broken and injured by the wind before maturity.

While it is possible to produce dates by depending on wind-pollination from male to female trees, this process is much too uncertain for commercial culture and requires a very large number of male trees. In commercial plantations, one male tree to 100 females is sufficient; but this requires that the pollinating shall be performed by hand. Small separate twigs or branchlets of the male inflorescence, from 4 to 6 inches long and bearing thirty to fifty flowers, are tied on the female cluster. Inasmuch as the flowers in the female

cluster mature at different times, it is necessary to repeat the operation of pollination. In old plantings, persons must climb the trees in order to perform this operation, but for the first ten or fifteen years of bearing the clusters are so near the ground that little if any climbing is required. Each female flower produces three ovaries. After pollination, two of these ovaries fail and one matures into the date. In case there is no pollination, all three of the ovaries will develop but will be seedless and the fruit will be inferior.

As with other fruits, it is often necessary to thin the dates on trees, particularly on young trees that tend to overbear. Even on old trees, best results are to be secured if only eight or ten bunches are left.

Usually the dates in an entire bunch do not ripen at the same time. Picking off the dates as they ripen is a practicable operation when labor is cheap. In general, however, it probably will be found the better plan to cut the entire bunch at once. This may require some special operation in the handling and curing. Some varieties require practically no special handling or curing and are ready to ship as soon as they have ripened naturally. Usually, however, the bunch must be ripened much as a bunch of bananas is cured, by being cut off and hung in a moist and warm place. It has been found that in Arizona the best varieties of dates may not ripen naturally on the tree. Freeman's experiments at the Arizona Experiment Station show that conditions favorable for the rapid ripening of the Deglet Noor may be produced artificially in an oven. The degree of moisture and temperature may be carefully regulated. In this ripening process, there is not only a

change in the sugar-content but the tissues of the date are softened, the tannin is precipitated and the astringency of the fruit is thereby relieved. Vinson found that dates may be ripened artificially by means of chemical reagents. Artificial ripening by means of heat, moisture, and chemical stimulation makes possible the production of commercial crops at altitudes too high and cool to mature many medium and late varieties. Losses by rain, insects, and birds are minimized, and greater cleanliness secured. Last year over half the crop from miscellaneous varieties at the Tempe Date Orchard (Arizona) would have been lost but for artificial methods of ripening. These methods are cheap and practicable. In connection with ripening operations, the fruit can be pasteurized at a temperature of 65° to 70° C (149°-158° F.) and then packed under

cheese-cloth to secure it from contamination by flies and other insects. Recent experiments by Drummond show that fumigation with carbon bisulfide kills insect eggs, and is preferable to pasteurization with varieties inclined to be sticky. In 1910, Swingle discovered the process now in use for ripening Deglet Noor dates by

1226. Fruit clusters of date, as grown in Arizona.

keeping them in moist atmosphere in closed packing-boxes which are kept warm at night and heated to 80° or 90° F. during the day. Deglet Noor dates ripen perfectly by this process and remain light-colored while those ripened by the rapid process are darkened. Freeman's rapid process will ripen greener dates, however.

For further discussion, see *Phoenix*; also the bulletins of the United States Department of Agriculture, and of the experiment stations of Arizona and California.

J. W. TOUMEY.

L. H. B.†

**DATÍSCA** (old Greek name, applied to some doubtful plant). *Datiscaceæ*. Tall perennial herbs, one of which is sometimes planted in gardens.

Glabrous branching hemp-like plants with pinnately compound or ternately divided alternate lvs., the lfts. or segms. lanceolate and usually serrate or toothed: fls. usually dioecious, the staminate fascicled in the axils and short-pedicelled, the pistillate racemose on axillary branchlets; stamens in sterile fl. 8-12-25, mostly opposite the calyx-lobes; stamens sometimes present in fertile fls. but few and perhaps alternate with calyx-lobes; ovary 3-angled at top, with 3 styles which are 2-parted: fr. a narrow ribbed many-seeded caps., opening between the styles at the top.—Species 2, one in S. E. Eu. and W. Asia, and the other in Calif. and Mex.; the former is in cult. abroad, requiring no special treatment; prop. by seeds and division.

The family *Datiscaceæ* is placed near *Begoniaceæ* and *Cactaceæ*. It comprises two other genera of tall trees, neither of which is recorded as in cultivation; these are *Octomeles*, with two species in the Malayan archipelago, and *Tetrameles*, with one species in East India to Java.

**cannabinā**, Linn. Three to 7 ft.: lvs. odd-pinnate; the lfts. of 3 pairs, 2 in. long, deeply serrate, long-acuminate: fls. small, yellow, the females in long and open racemes. Eu.—Attractive bushy plants with graceful foliage; both sexes should be grown, the female being the finer for ornament.

*D. glomerata*, Brew. & Wats., the American species, is apparently not in cult.: 2½-4 ft., stout, glabrous, the sts. clustered: lvs. ternately divided or lobed: staminate fls. in clusters of 3; pistillate fls. 4-7 together or scattered along short branchlets. It is the durango-root of the Coast ranges and Sierra Nevada.

L. H. B.

1227. A triple form of *Datura fastuosa*, commonly known as *D. cornucopia*.

**DATŪRA** (Arabic name). Syn. *Brugmānsia*. *Solanaceæ*. THORN-APPLE. Several large plants cultivated for their huge trumpet-like flowers, which have an odor that is very pleasant to some persons.

Annual or perennial herbs, shrubs, and trees: lvs. large, entire or wavy-toothed: fls. large, solitary, erect or pendulous, mostly white, with more or less violet, rarely red or yellow; calyx 5-toothed, sometimes breaking apart near the base or splitting lengthwise; corolla trumpet-shaped, with spreading 5-10-toothed

limb; stamens 5, all perfect, slightly or not at all exserted, the filaments slender; style long, the stigma 2-lobed: fr. a large 2-celled caps., mostly prickly or spiny, usually dry and 4-valved at top but sometimes fleshy and bursting irregularly, with large seeds.—Some 15 species, mostly strong-smelling, in the warmer parts of the globe, some of them weeds.

A few daturas are grown as flower-garden subjects, or the shrubby kinds under glass or as tub specimens. The most popular kind in northern gardens is commonly called *D. cornucopia* (Fig. 1227), which is especially interesting when its flowers develop two or three well-defined trumpets, one within another. Sometimes, however, these double flowers are a confused mass of petalage. Double and triple forms are likely to occur in any of the species described below. The horn-of-plenty has been especially popular in America since about 1895, when it was found in South America by an orchid collector of the United States Nursery Company, and soon became widely distributed in "yellow, white, blue and deep carmine," all double forms. Daturas contain strong narcotics. Large doses are poisonous, small doses medicinal. Separate preparations of *Stramonium* seed and leaves are commonly sold in the drugstores. *D. Stramonium* (Fig. 1228) is the thorn-apple or Jamestown weed, the latter name being corrupted into jimson weed. Its foul, rank herbage and large spiny fruits are often seen in rubbish heaps. At the first successful settlement in America—Jamestown, Virginia, 1607—it is said that the men ate these thorn-apples with curious results. Capt. John Smith's account of their mad antics is very entertaining. It has been conjectured that this same plant was used by the priests at Delphi to produce oracular ravings. The seeds of *D. sanguinea* are said to have been used by Peruvian priests that were believed to have prophetic power.

Daturas are of easy culture. Some are treated as tender annuals. In the North the woody species can be grown outdoors in summer, and stored in cellars during the winter; in the South and in southern California they are almost everblooming. They are sometimes kept in cool conservatories the year round, in which case they should be planted in the border, as they rarely flower well in pots, their roots being large and spreading and requiring a constant supply of moisture. This method produces great quantities of bloom in spring. After flowering, the plants should be cut in to the main limbs.

#### A. Fls. red.

**sanguinea**, Ruiz & Pav. Tree-like shrub, 4-12 ft. high: branches fragile, leafy at the apex: lvs. clustered, 5-7 from the same point, ovate-lanceolate, acuminate, almost 7 in. long, 2½-2¾ in. wide, pubescent on both sides, shining green above, paler beneath, the lower lvs. wavy or angled, upper one entire; petioles 2½ in. long, channeled, pubescent; peduncles terminal; fls. pendulous, brilliant orange-red, about 8 in. long; calyx ovate, 5-angled, variegated, inflated. Peru. B.R. 1739 (as *B. bicolor*). F.S. 18:1883.—All the other species are said to be easily raised from cuttings, but this is very slow to take root.

#### AA. Fls. yellow.

**chlorántha**, Hook. Shrub, glabrous throughout: lvs. broadly ovate, almost triangular; margin wavy, with short, rather sharp, very distinct teeth: peduncles axillary, very short; fls. pendulous, yellow; calyx tubular, with 5 nearly uniform, short, triangular teeth. Habitat unknown. B.M. 5128. Gn. 46:429; 49, p. 379.—*Datura* "Golden Queen" is presumably a horticultural variety of this species. While this species is horticulturally distinct by reason of its yellow fls., it is a doubtful species botanically, being founded on a very double garden form of unknown origin. In Vilmorin's

Blumengärtnerei, by Voss, it is referred to *D. humilis*, Desf., but *D. humilis*, in turn, is perhaps a form of *D. fastuosa*.

AAA. Fls. normally white (sometimes touched with violet) or purple.

B. Plants tall, 7–15 ft. high; blossoms pendulous.

c. Calyx tubular, with 5 obscure teeth.

*suaveolens*, Humb. & Bonpl. (*D. Gärdeni*, Hook.). ANGEL'S TRUMPET. Tree-like shrub, 10–15 ft. high; lvs. ovate-oblong, 6–12 in. long,  $2\frac{1}{4}$ –4 in. wide, entire, glabrous, petioled, often unequal at the base; fls. 9–12 in. long; calyx inflated, angled, glabrous, with 5 obscure teeth; corolla-tube plaited, the limb with 5 short lobes; anthers crowded together. Mex. G.C. III. 11:593; 23:71. S.H. 2:433.—The double form is much commoner in the gardens than the single. This is the plant which is usually cult. as *D. arborea*. It is said to be very distinct from the true *D. arborea* of Linn., but it can be separated with certainty by the calyx.

cc. Calyx spathe-like, not toothed.

*arborea*, Linn. (*Brugmansia arborea*, Steud.). ANGEL'S TRUMPET. Small tree: lvs. ovate-lanceolate, margin entire, never wavy or angled, pubescent, in pairs, one a third shorter than the other; petioles 1 in. or more long; fls. with a musk-like odor; calyx tubular, entire, spathe-like, acuminate; corolla-tube terete, the lobes of the limb very long; anthers distinct, not conglomerate. Peru and Chile. G.C. II. 11:141.—Most of the plants cult. under this name are presumably *D. suaveolens*. The extent to which the true *D. arborea* is cult. is undetermined.

BB. Plants less tall, only 2–5 ft. high.

c. Blossoms erect; calyx not spurred.

*fastuosa*, Linn. (*D. Hummātu*, Bernh. *D.* and *B. corracopia*, Hort.). Fig. 1227. Annual, 4–5 ft. high, herbaceous: lvs. ovate-lanceolate, acuminate, acute and unequal at the base, toothed or wavy, glabrous on both sides, solitary, upper ones in pairs one of which is larger, 7–8 in. long,  $2\frac{1}{2}$ – $3\frac{1}{2}$  in. wide; petioles  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. long; fls.  $6\frac{1}{2}$ –7 in. long, violet outside, whitish within; calyx purple, angled, 2 in. long, 5-toothed, the teeth triangular lanceolate, acuminate, 5 lines long, 2–3 lines wide; caps. spiny, subglobose,  $1\frac{1}{4}$  in. diam. Native of India. Naturalized in the tropics of both worlds. F.S. 14:1457. Gn. 46:224. I.H. 42:25.—The commonest garden datura. Resembles the common *D. Stramonium*, but fls. larger. Var. *alba*, Clarke (*D. alba*, Nees), has fls. white or nearly so. (*D. alba* var. *africana*, Fedde, is distinguished by its larger lvs., longer calyx, and corolla glabrous outside. Italian Somaliland.) Var. *dubia*, Clarke (*D. dubia*, Don. *D. Nilhummatu*, Dunal), has spineless frs. Var. *Huberiana*, Hort., is a thick bushy cult. form with large fls. of several colors, running into yellowish, blue and red; it is said to be a hybrid with *D. chlorantha*.

*meteloides*, DC. (*D. Wrightii*, Hort.). Perennial (cult. as an annual N.), glaucescent and puberulent: branches slender, forked: lvs. unequally ovate, almost entire, acuminate, acute at both ends, upper lvs. often in pairs, the larger  $2\frac{1}{4}$  in. long, 8–9 lines wide; petioles thickened at the base, 4–5 lines wide; calyx tubular, the teeth mostly 5; corolla about 4–8 in. long, or twice as long as the calyx, 5-toothed, the teeth slender-subulate: caps. 2 in. diam., succulent, prickly. Texas to Calif. Gt. 1859:260. R.H. 1857, p. 571. F.S. 12:1266.—Fls. white, suffused with violet, fragrant. Occurs also in Northern Mex.

cc. Blossoms pendulous; calyx with a long spur.

*cornigera*, Hook. (*D.* and *B. Knightii*, Hort.). Height 3–4 ft.: branches downy: lvs. chiefly at the ends of branches, ovate, petioled, acuminate, margin entire, wavy or angled: fls. pendulous, white or creamy white,

very fragrant at night, striated, 5-lobed, the lobe terminated by a long awl-shaped spreading or recurved point; stamens included. Mex. B.M. 4252. *Brugmansia Knightii* seems to be a trade name for only the double form. Gn. 45, p. 549.

Weedy annual species of *Datura*, intro. from the tropics or warm countries and run free in this country, are: *D. Metel*, Linn. Pubescent: lvs. entire or slightly toothed; calyx tubular; corolla-limb 10-lobed, 4 in. across: caps. nodding, prickly: 3–5 ft.: fls. white.—*D. Stramonium*, Linn. Fig. 1228. The common stramonium or jimson-weed: glabrous, green-stemmed; lvs. ovate, sinuate or angled or even cut-toothed: caps. erect, with stout prickles: 2–4 ft.: fls. white. A very similar species but with a smooth and spineless caps. is *D. inermis*, Jacq.—*D. Tatula*, Linn. Differs from *C. Stramonium* in having purple sts., and violet-purple or lavender fls., and prickles of the caps. more nearly equal.

1228. Pods of *Datura Stramonium*. ( $\times\frac{1}{3}$ )

Other daturas more or less cult. abroad are: *D. ceratocaula*, Ort. Annual, 2 ft.: branches horn-shaped: lvs. broad-lanceolate: fls. very large, inside white or light violet, outside bluish, opening late in afternoon till middle of forenoon: fr. hanging, smooth. Trop. Amer. B.M. 3352.—*D. coccinea*, Hort.—*D. De Noteri*.—*D. colosseus aurea*, Hort. Garden hybrid, parentage not reported, with bright golden yellow fls.—*D. De Noteri*, Hort. Probably annual: 3 ft.: fls. fragrant, brilliant red, freely produced. S. Afr.—*D. ferox*, Linn. St. thick, glabrous, red at base but otherwise green or white-punctate: lvs. rhombic-ovate, angled-toothed: calyx 5-angled and about 5-parted; corolla light blue, the limb angulate: fr. unequally spiny, with 4 large spines at top. S. Eu.—*D. quercifolia*, HBK. Annual, with green sts., the young growth somewhat pubescent: lvs. deeply sinuate-pinnatifid: fls. as in *D. Tatula*: caps. bearing large and unequal flattened prickles that are sometimes  $\frac{1}{2}$  in. long. Mex.

WILHELM MILLER.  
L. H. B.†

DAUBENTONIA: *Sesbania*.

DAUCUS (ancient Greek name). *Umbelliferae*. Perhaps 60 annual and biennial herbs of very wide distribution. One or 2 species are native to N. Amer.; one species of *Daucus* is the common garden carrot, and the wild form of the same species is an abundant old-field weed in the northeastern states. Aside from the carrot, there are no horticultural members of the genus. *Daucus* comprises bristly or setose slender plants, with pinnately decomposed and often finely divided lvs., very small fls. in compound involucre umbels, and oblong mostly dorsally flattened frs. The species are mostly of the temperate regions of Eu., Afr. and Asia.

*Carda*, Linn. Figs. 821, 822. Bristly biennial, with twice- or thrice-pinnatifid lvs., the ultimate divisions cut and pointed: fls. crowded in umbels, mostly white but sometimes blush or even pale yellow, some of the marginal fls. larger; rays of umbel numerous; involucre of many elongated-subulate divisions: fr. (or "seed") small, greenish or brownish, somewhat convex on one side and plane on the opposite side

grooved, bristly, aromatic. Eu. Under cult., the root has been greatly developed into many edible forms.

Var. *Boissieri*, Schweinf., from Egypt and also in Spain, has blood-red or violet-colored roots. Gt. 1904:1527.

L. H. B.

**DAVALLIA** (a personal name). *Polypodiaceæ*. Ferns, some of them grown under glass, and the smaller species making good plants for hanging-baskets.

Tropical plants, usually with firm, somewhat finely divided foliage and coriaceous semi-cylindric indusia, which are attached at both the base and sides, opening toward the margin of the leaf.—Some twenty species, in many parts of the globe, some of them epiphytes.

The diverse habits of growth of the many different species of *davallias*, and their good lasting qualities, peculiarly fit them under ordinary care for decorative purposes, when delicate and graceful plants are desired. Among the many species, the following are most often seen and best adapted for commercial purposes: *D. bullata*, *D. parvula*, very dwarf; *D. pentaphylla*, young fronds of a dark bronzy green, and *D. Tyermanni* (Humata), are well adapted for hanging-baskets. *D. dissecta* and var. *elegans*, *D. concinna* (*Loxoscaphe*), *D. fijiensis* and vars. *plumosa* and *major*, *D. faniculacea* (*Loxoscaphe*), *D. solida*, *D. pallida* (syn. *Mooreana*) and *D. pyxidata* are adapted for large specimen plants. *D. tenuifolia* (*Odontosoria chinensis*) and vars. *stricta* and *Veitchiana* are desirable for fern-dishes, because of their dwarfish habit of growth and the ease with which they may be raised from spores.—Old plants of *davallia* may be cut into a number of smaller ones with a sharp knife. Planted firmly into shallow pans and placed in a temperature of 60° to 65° F., they soon develop into symmetrical plants. The rhizomes should be firmly fastened to soil by strong copper-wire staples, where they will root in a short time. To gain a large number of small plants, the rhizomes should be detached, cleaned from all soil and roots, laid on sand and thinly covered

with moss. Placed in a shaded position in a temperature of 65° to 70° F., and kept moderately moist, a number of small plants will develop from the dormant eyes, which may be separately potted as soon as of sufficient size. Spores of *davallia* should be sown on a fine compost of soil, leaf-mold or peat and sand in equal parts, and placed in a shaded position in a temperature of 60° to 65° F. All the operations of propagation of *davallias* will be most successful if conducted during the spring months. All *davallias* delight in a rich and open compost, an abundance of light and air, and moisture at their roots, a temperature of 60° to 65° F. and a thorough syringing every bright day. (N. N. Bruckner.)

# INDEX.

bullata, 3.	fijiensis, 10.	parvula, 2.
canariensis, 8.	major, 10.	pentaphylla, 1.
decurrens, 6.	Mariesii, 4.	plumosa, 10.
denticulata, 5.	Mayi, 6.	polyantha, 12.
dissecta, 11.	Mooreana, 13.	pyxidata, 9.
divaricata, 12.	ornata, 7.	solida, 7.
elegans, 5, 8, 11.	pallida, 13.	superba, 7.

## A. Lvs. once pinnate, with few linear segms.

1. *pentaphylla*, Blume. Lvs. scattered, from a stout fibrillose rootstock, 1-pinnate, with 1 terminal and 4-6 pairs of lateral pinnæ, 4-6 in. long, ½ in. broad; sori in marginal rows. Java and Polynesia.

## AA. Lvs. tri- or quadri-pinnatifid, deltoid.

### B. Length of lvs. less than 1 ft.

2. *parvula*, Wall. A tiny fern with scaly creeping rootstocks, the lvs. sessile or with stalks 1-2 in. long, the blades ½-¾ in. long, ½ in. broad, triangular, 2-3 pinnatifid, the segms. threadlike, pointed. Singapore and Borneo.

3. *bullata*, Wall. Figs. 1229, 1230. Rootstock creeping, clothed with whitish or light brown hair-like scales: lvs. scattered, 6-10 in. long, 4-6 in. wide, quadri-pinnatifid, with deeply incised segms.; texture firm. India to Java and Japan. F.E. 11:543.—Often sold for house cult. in the form of a fern-ball.

4. *Mariesii*, Moore. Rootstock stout, with brownish scales, which are lanceolate from a broad dilated base: lvs. deltoid, 4-6 in. each way, with the pinnæ cut away at the lower side at base; segms. short-linear, 1-nerved; sori intramarginal. Japan. G.C. III. 13:571.

### BB. Length of lvs. 1-2 ft.

#### C. Foliage commonly tri-pinnatifid.

5. *denticulata*, Mett. (*D. elegans*, Swartz). Rootstock clothed with woolly fibers: lvs. 9-15 in. wide, with the main rachis slightly winged toward the apex; indusia several to a segm., with the sharp teeth projecting beyond the cups. Ceylon to Austral. and Polynesia.

6. *decurrens*, Hooker. Rootstock stout, creeping, fibrillose: lf.-blade 1-2 ft. long, 9-15 in. broad, triangular, the main rachis scarcely winged at the apex, 3-pinnate, the segms. linear-oblong, broadly toothed; sori inside the margin. Philippines. Var. *Mayi*, Hort. Graceful, much divided lvs.

7. *solida*, Swartz (*D. ornata*, Wall.). Rootstock clothed with appressed scales or fibers: lvs. 1-2 ft. long, 12-15 in. wide, the center of the apex broad and undivided; segms. broad and slightly cut; indusia marginal. Malaya. Var. *superba*, Hort. Lvs. flat, in young state tinted with red.

#### cc. Foliage commonly quadri-pinnatifid.

8. *canariensis*, Smith. Rootstock stout, densely clothed with pale brown linear scales: lf.-blades 12-18 in. long, triangular, with ovate-rhombic, deeply incised segms.; sori on entire segms., or with a horn outside. Spain, Canaries, N. Afr. Var. *elegans*, Hort. Lvs. finely divided.

9. *pyxidata*, Cav. Rootstock clothed with pale brown linear scales: lf.-blades tri-quadri-pinnatifid, 6-9 in. broad, with oblong segms.; sori with a broad space outside, which is extended into a horn-like projection. Austral.

10. *fijiensis*, Hook. Lvs. 6-12 in. broad, with the lower pinnæ deltoid and the segms. cut into narrow, linear divisions ½-¾ in. long; sori on the dilated apices of the segms. with no horn. Fiji Is. A.F. 6:900; 9:233. G.C. III. 23:323.—One of the finest species, with numerous varieties. Considered by some botanists to be a variety of *D. solida*. Var. *plumosa*, Bull. Distinct from the species by the gracefully drooping habit and feathery nature of the pendulous lvs. Var. *major*,

Moore. More robust: lvs. not so fine, lighter color than the species.

11. *dissécta*, J. Smith. Rootstock stout, with dense, rusty scales: lvs. 10-12 in. broad, on straw-colored stalks; segms. oblong, cuneate at base, with simple or bifid lobes; sori minute, often with 2 projecting horns. Java. Var. *élegans*, Hort. Similar to type but with more graceful habit.

BBB. Length of lvs. 2-3 ft.

12. *divaricâta*, Blume (*D. polyântha*, Hook.). Rootstock with linear rusty scales: lvs. tri-pinnatifid, sometimes 2 ft. broad, with deltoid segms. cut into linear-oblong lobes; sori at some distance from the edge. India to Java and Hong Kong.

13. *pállida*, Mett. (*D. Mooreana*, Mast.). Rootstock stout, with lanceolate dark brown scales: lvs. with straw-colored stalks 12-18 in. long, quadri-pinnatifid, with deltoid, stalked segms., the ultimate obovate-cuneate, bearing the sorus on the upper side at the base. Aneityum and Borneo. A.F. 6:901; 9:231. A. G. 13:143.

For *D. concinna* and *D. feniculacea*, see *Loxoscaphe*. *D. platyphylla*, see *Microlepia*; *D. stricta*, see *Stenoloma*; *D. tenuifolia*, see *Stenoloma*; *D. Tyermanni*, see *Humata*.

Several other ferns are in trade under the name *Davallia*, which are properly referred to other genera. Of these, disposition should be made as follows: *D. alpina*=*Humata repens*; *D. angustata*=*Humata heterophylla*; *D. brasiliensis*=*Saccoloma inaequale*; *D. retusa*=*Odontosoria retusa*; *D. tenuifolia*=*Odontosoria chinensis*. *D. amena* and *D. decora* are names of uncertain standing and application.

R. C. BENEDICT.†

**DAVÍDIA** (after Armand David, French missionary, botanized in China from 1862 to 1873). *Nyssaceæ*. Ornamental deciduous trees, cultivated for their handsome foliage and the large and showy white flowers.

Leaves alternate, slender-petioled, dentate, without stipules: fls. polygamous, in dense subglobose heads consisting of numerous staminate fls. and 1 bisexual fl., with 2 large bracts at the base; sepals and petals wanting; stamens 1-7, with slender filaments; ovary 6-10-celled, with rudimentary perianth and a circle of short stamens on top of the ovary at the base of the short and thick style, with spreading stigmas: fr. a drupe with a 3-5-seeded stone.—One species in W. China.

This is a handsome tree of pyramidal habit, with rather large and attractive bright green foliage, and an object of striking beauty when studded with the very large creamy white floral bracts. The tree has proved hardy in favorable positions as far north as Massachusetts; it seems to be somewhat tender only while young. Apparently it grows well in any good fresh soil. Propagation is by seeds sown in spring, which soon germinate, and by cuttings in summer of half-ripened wood under glass; also by layers.

*involutocrâta*, Baill. Pyramidal tree, to 60 ft., with upright or ascending branches: lvs. cordate-ovate, acuminate, coarsely serrate, strongly veined, bright green and finally glabrous above, densely silky pubescent below, 2¼-5 in. long; heads terminal, peduncled; bracts 2, opposite, rarely 3, ovate to oblong-obovate, entire or serrate, creamy white, of unequal size, the larger to 7 in. long and to 4¼ in. broad; drupe oblong-ovoid, brownish, punctulate, about 1½ in. long. May, June: fr. in Oct. W. China. Var. *Vilmoriniâna*, Hemsl. (*D. Vilmoriniâna*, Dode. *D. læta*, Dode). Lvs. glabrous and glaucescent below, or only sparingly pubescent while young. B.M. 8432. H.I. 20:1961. G.C. III. 33:235; 39:346. J.H.S. 1903:57; 37:129, fig. 113. R.H. 1906, pp. 297-9; 1907, p. 321. R.B. 34:230. This variety is better known in cult. than the type. It was intro. in 1897 by Farges who sent seeds

from which a single plant was raised by Vilmorin. Later E. H. Wilson sent seeds of the variety as well as the type, from which a large stock of plants was raised by Veitch.

ALFRED REHDER.

DAY FLOWER: *Commelina*.

DAY LILY: *Funkia* and *Hemerocallis*.

DEAD NETTLE: *Lamium*.

**DEBREGEASIA** (derivation unknown; probably named after a person). Syn., *Morocârpus*. *Urticaceæ*. Upright shrubs, grown for their handsome foliage and ornamental yellow or red fruits, which are edible.

Leaves alternate, short-petioled, serrulate, 3-nerved at the base, rugose above, tomentose beneath; stipules bifid: fls. monœcious or diœcious in unisexual globose clusters arranged in small axillary cymes; staminate fls. with usually 4-parted perianth, with 4 short stamens; pistillate with urceolate or obovate perianth much contracted at the mouth, with very short usually 4-toothed limb, adnate to the ovary; stigma penicillate, on a short style or sessile: fr. subglobose consisting of numerous small 1-seeded fleshy drupelets.—Five or 6 species in China, S. Asia and Abyssinia.

The two species in cultivation, neither of which is yet in trade, are spreading tender shrubs with handsome slender foliage, dark green above, whitish below,

and small usually orange-red fruits resembling in shape a small mulberry and produced profusely along last year's branches. *D. longifolia* is a stove-plant; *D. edulis* is hardier, and at the Arnold Arboretum survives the winter outdoors. It is, however, killed back nearly to the ground, but sends up numerous shoots, and although it does not flower and fruit, it is an attractive bush on account of the striking contrast of the dark green lustrous upper and the white lower surface of the leaves. Propagation is by seeds and by green-wood cuttings under glass.

*edulis*, Wedd. (*Morocârpus edulis*, Sieb. & Zucc.). Shrub, to 6 ft.: branchlets appressed-pubescent, soon glabrous: lvs. oblong-lanceolate to elliptic, acuminate, serrulate, rugose and smooth above, whitish tomentose below, 3-5 in. long; fr. orange-red, globose, about ½ in. across, in small dichotomous cymes in June. China, Japan.

*longifolia*, Wedd. (*D. velutina*, Gaud. *Conocéphalus niveus*, Wight). Shrub, to 8 ft.: branchlets villous: lvs. lanceolate to oblong-lanceolate, acuminate, serrulate, rugose and rough above, white-tomentose beneath, 4-7 in. long; fr. orange-yellow or red, ½ in. across, in small dichotomous cymes. Subtropical Himalaya to Java. R.H. 1896, p. 321. G.C. III. 39:232, suppl.

ALFRED REHDER.

DECABELONE: *Tavaresia*.

**DECAISNEA** (after Joseph Decaisne, French botanist, who wrote much on the botany of cultivated plants; 1809–1882). *Lardizabalaceæ*. Woody subjects grown for the large pinnate foliage and the conspicuous fruits.

Upright sparingly branched shrubs: lvs. odd-pinnate, large, with opposite entire lfts.: fls. polygamous, in axillary racemes, slender-pedicelled; sepals 6, petaloid, long-acuminate; petals wanting; stamens 6, the filaments in the staminate fl. connate into a column; pistils 3, growing into rather large oblong follicles with numerous seeds in two ranks imbedded in a white pulp.—Two species in E. Himalayas and in W. China.

These are distinct-looking shrubs, in habit resembling a large-leaved sumac, with long racemes of pendulous greenish flowers similar in shape to those of a yucca, but are smaller, and with conspicuous blue or yellow fruits which are edible, but insipid. The Chinese species has proved hardy at the Arnold Arboretum in sheltered position, while the Himalayan is tender. They prefer a sheltered situation of warm southern exposure and do not seem particular as to the soil. Propagation is by seeds.

**Fargesii**, Franch. Shrub, to 15 ft.: lvs. to 3 ft. long, glabrous; lfts. 13–25, elliptic, acuminate, short-petioled, bright green above, glaucescent below, 2–5 in. long: racemes upright, many-fld.; fls. nodding, campanulate, greenish, 1–1½ in. long; sepals lanceolate, long-acuminate, much longer than the stamens: fr. pendulous, oblong-cylindric, deep blue, 3–4 in. long, about 1 in. thick, with numerous black seeds about ½ in. long: April, May; fr. in Sept. W. China. B.M. 7848. R.H. 1900, pp. 270, 271, 273. M.D. 1912:197.

*D. insignis*, Hook. f. & Thoms. In habit, lvs. and fls., very little different from the preceding species, but fr. yellow, thicker, curved. E. Himalayas. B.M. 6731. F.S. 13:1335. I.H. 3:91.

ALFRED REHDER.

**DÉCODON** (Greek, *ten-toothed*). *Lythraceæ*. A hardy perennial herb sometimes offered by dealers in native plants. Decodon is sometimes considered a subgenus of *Nesaea*, but is latterly kept distinct as a monotypic genus. It is distinguished from *Lythrum* by having 5 (rarely 4) petals instead of 6, and 10 stamens while *Lythrum* has mostly 6 or 12. It has opposite or whorled lvs., the upper with axillary, short-stalked clusters of fls.

**verticillatus**, Ell. (*Nesaea verticillata*, HBK.). SWAMP LOOSE-STRIPE. WATER-WILLOW. Smooth or downy: sts. recurved, 2–8 ft. long, 4–6-sided: lvs. lanceolate, nearly sessile: petals 5, cuneate-lanceolate, rose-purple, ½ in. long; stamens 10, half of them shorter. Swampy grounds, N. E. to Fla., west to Minn. and La.—Desirable for colonizing about ponds and in very wet places. It runs into 2 or 3 varieties.

**DECUMARIA** (Latin, *decumus*, tenth, referring to the number of the parts of the flower). *Saxifragaceæ*. Climbing shrubs, cultivated for their handsome glossy foliage and clusters of attractive white flowers.

Climbing by aerial rootlets: lvs. deciduous, opposite, petioled: fls. in terminal peduncled corymbs, small, white, perfect; sepals and petals 7–10; stamens 20–30: fr. a 5–10-celled ribbed caps. opening between the ribs, with numerous minute seeds.—One species in E. N. Amer. and one in China.

These are ornamental climbing shrubs with handsome glossy foliage and fragrant white flowers, forming a corymb of feathery appearance, well adapted for covering walls, rocks, trellis work and trunks of trees; tender, but the American species survives in sheltered positions as far north as Massachusetts, while the Chinese is more tender. They thrive in almost any humid soil. Propagation is by greenwood cuttings in summer under glass, rarely by seeds.

**bárbara**, Linn. (*D. sarmentosa*, Bosc). Climbing to 30 ft., but usually less high: lvs. ovate, obtuse or acute, remotely denticulate or entire, glabrous and shining above, 2–4 in. long and 1–2 in. broad: corymbs 2–3 in. broad, semiglobose. May, June. Va. to Fla., west to La. B.B. (ed. 2) 2:233. Mn. 1:41. G.C. III. 46:242, suppl.

*D. sinensis*, Oliv. Very similar to the preceding; less high: lvs. generally oblong, obtuse or obtusish, 1½–3 in. long and ½–1 in. broad: pedicels appressed-pubescent. Cent. China. H.I. 18:1741.

ALFRED REHDER.

**DEERBERRY**: *Vaccinium stamineum*.

**DEERGRASS**: *Rhexia*.

**DEERÍNGIA** (Karl Deering, died 1749; born in Saxony, practicing physician in London and author of catalogue of plants of England). *Amarantaceæ*. About a half-dozen species of climbing herbs or sub-shrubs, from Madagascar to Austral., one of which is offered in Calif. Lvs. alternate: fls. dioecious or perfect, numerous and small, in terminal spiciferous panicles; parts of fl. 5, spreading under the succulent indehiscent fr.; stamens 5, united into a ring. **D. baccata**, Moq. (*D. celosioides*, R. Br.), in Austral., E. Indies and elsewhere, is a smooth woody climber, 10–12 ft.: lvs. ovate or ovate-lanceolate, acuminate, entire: fls. in slender interrupted spikes 1 ft. or less long, greenish white: berry red, nearly globular, ¼ in. or less diam. B.M. 2717. The plant offered as *D. variegata*, described as a slender-growing shrub that will climb if shoots are trained up, long spikes of white fls., and lvs. margined with white, is probably a form of this species, or it may be *Bosea Amherstiana* (*D. Amherstiana*, Wall.), which has a form with variegated lvs.

L. H. B.

**DEINÁNTHE** (Greek *extraordinary*, referring to the flowers being large for the group). *Saxifragaceæ*. Herbs or sub-shrubs of 2 species, 1 in Japan and 1 in China, at least the Chinese species having been offered in England. Of the *Hydrangea* tribe, allied to *Cardiandra*, but lvs. opposite rather than alternate and style 1–5-forked rather than 3 and separate. *D. cærulea*, Stapf, from China, is a perennial herb, 1–1½ ft. high, with horizontal stout rootstock, the solitary st. from the tip of the rootstock: lvs. about 4 at the top of the st., ovate or broad-elliptic, sharply toothed: fls. sterile and fertile, the former few, the fertile much larger and nodding, the petals bright blue, stamens blue, all constituting a terminal panicle. B.M. 8373. *D. bifida*, Maxim., has creamy white or pure white fls. with yellow stamens, a different infl. and lvs. deeply bifid at apex.

L. H. B.

**DELABÉCHEA RUPESTRIS**: *Sterculia rupestris*.

**DELÁRBREA** (after a French naturalist). *Araliaceæ*. Tall tender shrubs from New Caledonia, grown in hot-houses.

Leaves alternate, decomposed, gracefully arching, the lfts. leathery and entire or slightly cut: fls. falling very early, in large umbellate-paniculate clusters, not very showy. Distinguished from *Aralia* by its round, not angled frs.—Two species. Cult. same as *Aralia*.

**spectabilis**, Lind. & André (*Arália concinna*, Nichols.). St. ashy gray, with brown, warty spots: lvs. odd-pinnate; lfts. in 8–10 pairs, each lft. entire or 3-toothed or twice cut, sometimes so deeply cut as to make 3 entirely free segms. I.H. 25:314.—Under the name of *Aralia spectabilis*, two different plants have been sold. One is *Aralia filicifolia*. The two plants can be distinguished at a glance. The primary division of the lf. in *A. filicifolia* is long and narrow, thrice as long as in *D. spectabilis*, and tapering to a long point, while in *D. spectabilis* the primary division of the lf. is short and has 3 well-marked segms. In *A. filicifolia* the secondary divisions are deeply and irregu-

larly cut; in *D. spectabilis* they are merely serrate. The two plants are also immediately distinguished by the black spots on the st. of *D. spectabilis*.

N. TAYLOR.†

**DELAVÀYA** (after J. M. Delavay, French missionary, who explored the flora of S. W. China). *Sapindaceæ*. A tree from S. W. China, allied to *Xanthoceras*, but differing chiefly in its 3-foliate lvs. and in the much smaller fls. with a cupular disk. The only species, *D. toxocarpa*, Franch. (*D. yunnanensis*, Franch.), is a small tree, to 25 ft.: lfts. lanceolate, serrate, glabrous, to 7 in. long; fls. about  $\frac{1}{2}$  in. across, white; fr. a 2-3-lobed woody caps. with large brownish black seeds. Reported as recently intro. but probably hardy in warmer temperate regions only. ALFRED REHDER.

**DELPHINIUM** (Greek, a dolphin, from the resemblance of the flower). *Ranunculaceæ*. LARKSPUR. A group of beautiful hardy plants grown in borders for their handsome spikes of flowers and stately stems of foliage. They are of great value for cut-flower purposes as the blooms keep well.

Annual or perennial, erect, branching herbs; lvs. palmately lobed or divided; fls. large, irregular, in a showy raceme or panicle; sepals 5, petal-like, the posterior one prolonged into a spur; petals 2 or 4, small, the posterior ones spurred, the lateral ones small, if present; the few carpels always sessile, forming many-seeded follicles. Full double forms are very common in a number of the species (compare Figs. 1232, 1233). A. Gray, An attempt to distinguish between the American Delphiniums, Bot. Gaz. 12:49-54, 1887. E. Huth, Monographie der Gattung Delphinium, in Eng. Bot. Jahrb. 20:322-499, 1895. There are about 60 species, native of the north temperate zone, four of which are of much greater popularity than the others: the annual, *D. Ajacis*, and the perennials, *D. grandiflorum*, *D. hybridum* and *D. formosum*. The last three have been especially prolific in named garden varieties. See page 3568.

Some of the garden varieties of delphiniums are as follows: King of Delphiniums, semi-double, and Duke of Connaught, distinguished by a deep intense blue and conspicuous white center of the large singular flowers; Mme. Violet Geslin and Julia, cornflower-blue varieties with white eye; Amos Perry, a combination of rich rosy mauve, flushed with sky-blue; Lizzie and Rev. J. J. Stubbs, spikes of vivid azure around deep brown centers. Combinations of sky-blue, pink and lavender are striking characteristics of Diademe, Excelsior, Grille, Hallgarten, Libelle, Minerva, Niederwald and Seidenspinner, distinguished from each other by white, brown or black centers. The petals of Carmen are of deep gentian-blue and pink, surrounding a brown center; those of Lamartine and Musea, lavender-blue; and Felicite, sky-blue.—Of the perpetual-flowering Belladonna class, the trade offers the following named hybrids: Capri, clear sky-blue; Moerheimeii, pure white; Nassau, Mr. Brunton and Persimmon variations in sky-blue and azure; while the light graceful spikes of Semiplenum and Grandiflora show a clear intense cornflower-blue.—Perfect double-flowering delphiniums, though very handsome, are shy seeders and a small percentage come true to color and variety. They do not seem to share in the great popularity of the singles. Of the latter the old species *D. chinense*, *D. Davidii*, and the rather hard to handle but otherwise beautiful yellow *D. Zaili*, are well worth cultivating. (R. Rothe.)

Rocket and Candelabrum are names used to designate the forms of inflorescence in the two annual species. The "Rocket" or spike-like form is more com-

monly found in the Ajacis type, and the "Candelabrum," with a number of short spike-like heads of different heights, is found more often in *Consolida*.

Delphiniums thrive in any good garden soil, but are improved by a deep, rich sandy loam, exposed to the sun. Deep preparation of the soil is very important. The annuals are propagated from seed, which are very slow in germinating. In the warmer latitudes they may be sown in early fall and will then produce flowers early the next season; or they may be started indoors.

The perennials, may be propagated: (1) By root-division in the fall or spring. The large strong-growing species may be divided into a number of plants after growing in the flower-bed for several years. (2) By cuttings, about which J. B. Keller says: "Take a few cuttings from each plant in early spring, when growth is about 3 or 4 inches long, or else use the second growth, which has come after the flower-stems have been removed. Cuttings root readily in a shaded frame, no bottom heat being required, but an occasional sprinkling during dry

and hot weather is necessary. When rooted they are treated like seedlings." (3) By seeds, started in the greenhouse or hotbed in March or even earlier. The young seedlings should be given plenty of room by transplanting as they grow, and may be set in the open garden by June. If started thus early they flower the first autumn. The seed may be planted in late spring or summer, care being taken to water well during dry weather, and flowers will come the next summer. To get the best results, the perennials should be transplanted every 2 or 3 years. Two good crops of blossoms may be secured in one season by cutting away the flower-stems of the first crop as soon as the flowers have faded; of

1231. *Delphinium Ajacis*. ( $\times \frac{1}{2}$ )

course no seeds will be produced in this way.

In most climates where they are grown the roots of the perennials are left unprotected, in the open garden, during the winter. This plan can be improved by giving the bed or border a good dressing of barnyard manure about the time the ground begins to freeze in the fall. This will greatly enrich the soil and also protect the underground buds during winter. A much better show of flowers will be the result. Because of their ability to use much fertility, it is well to spade in the manure instead of removing it in the spring. A top-dressing of manure near the plants in midsummer is used to aid in forcing the "fall" or second crop of flowers. This dressing conserves the soil-moisture, prevents weeds, and adds plant-food. Such applications of manure will make the plants more vigorous throughout. They will flower more profusely and, if desired, the roots can be divided much more freely.

## A. Annuals: petals only 2, united: follicle 1.

1. *Ajacis*, Linn. Fig. 1231. An erect annual, about 18 in. high, with a few spreading branches: lvs. of st. sessile, deeply cut into fine, linear segms.; root-lvs. similar, but short-petioled: fls. showy, blue or violet, varying to white, more numerous than in *D. Consolida*, in a spicate raceme; petals 2, united; calyx-spur about equaling the rest of the fl.: follicle only 1, pubescent; seeds with wrinkled, broken ridges. May–Aug. Eu. R.H. 1893, p. 228. Same figure in S.H. 2:282.—The season of flowering is governed largely by the time of sowing the seeds. If sown in the fall, as may be done in warm climates, the plants will produce fls. by May or June. But if the seeds be sown in spring no fls. should be expected before July or Aug.

2. *Consolida*, Linn. (*Consolida arvensis*, Opiz). An erect, hairy annual, 1–1½ ft. high: lvs. similar to *D. Ajacis*: fls. few, loosely paniced, pedicels shorter than the bracts, blue or violet or white; petals 2, united: follicle 1, glabrous; seeds with broken, transverse ridges. June–Aug. Eu. Baxter Brit. Bot. 4, t. 297. R.H. 1893, p. 228 (var. *ornatum Candelabrum*). G.Z. 15:81. Var. *imperialis*, Hort. (*D. imperialis fl. pl.*, Hort.). Fls. double. From the English gardens.—See above species for sowing of seeds.

## AA. Perennials, pure species: petals 4: follicles 3–5 (Nos. 3–27).

## B. Sepals red.

3. *nudicaule*, Torr. & Gray. St. 1–1½ ft. high, glabrous, branched, few-lyd.: lvs. rather succulent, 1–3 in. across, lobed to the middle or farther 3–7 times, the secondary lobes rounded and often mucronate; petioles 3–5 in. long, dilated at the base: fls. paniced; sepals bright orange-red, obtuse, scarcely spreading, shorter than the stout spur; petals yellow, nearly as long as sepals; follicles 3, spreading and recurved, soon becoming glabrous; seeds thin-winged. Apr.–July. Along mountain streams, N. Calif. B.M. 5819. F.S. 19:1949. R.H. 1893, p. 259.—A good perennial in the E.

1232. Single larkspur.  
 —*D. grandiflorum*.

4. *cardinale*, Hook. St. erect, 2–3½ ft. high and much higher under favorable conditions, partly pubescent: lvs. smooth, fleshy, deeply 5-parted, the parts cut into long, linear lobes: raceme elongated, many-fl.; fls. bright red, with petal-limbs yellow: follicles glabrous, usually 3; seeds smooth. July, Aug. S. Calif. B.M. 4887. Gt. 6:328. F.S. 11:1105. R.B. 6:101. Gn. 19:234.

## BB. Sepals clear yellow or tipped with blue.

5. *Przewalskii*, Huth (*D. Przewalskianum*, Hort.). Nearly glabrous, often branched at base, erect, varying much in height: lvs. 3–5 times deeply parted, parts

divided into narrow, obtuse lobes: fls. clear yellow, or sometimes tipped with blue; spur equaling the sepals: follicles 3, densely hairy. July, Aug. Asia.—Intro. 1892.

6. *Zalil*, Aitch. & Hemsl. (*D. sulphureum*, Hort. *D. hybridum* var. *sulphureum*, Hort.). St. nearly simple, erect, 1–2 ft. high, rather glabrous, or becoming so: lvs. of several narrow, linear lobes, dark green; petioles not dilating at the base: fls. large, light yellow, in long racemes: follicles 3, longitudinally furrowed and ribbed; seeds with transverse, fibrous plates. June, July. Persia. Intro. 1892. B.M. 7049. Gn. 50:434; 54, p. 347; 71, p. 285. G.C. III. 20:247.—Seedlings from tubers and plants die down as if dead; but they make a second growth after a short period of rest.

1233. Double larkspur.—  
*D. grandiflorum*.

## BBB. Sepals blue or varying to white.

## c. Height 1½ ft. or less.

## D. Petioles dilating at the base.

7. *bicolor*, Nutt. Erect, rather stout, ½–1 ft. high, from fascicled roots: lvs. small, thick, deeply parted and divisions cleft, except perhaps in the upper lvs.; segms. linear and obtuse: raceme rather few-fl., the lower pedicels ascending 1–2 in.; spur and sepals nearly equal, ½ in. long or more, blue; upper petals pale yellow or white, blue-veined; lower petals blue: follicles glabrous or becoming so. May–Aug. Dry woods, Colo., west and north to Alaska.

8. *Brunonianum*, Royle. MUSK LARKSPUR. Sts. erect, ½–1½ ft. high: plant somewhat pubescent: upper lvs. 3-parted, lower ones reniform, 5-parted; segms. deeply cut, musk-scented: fls. large, light blue with purple margins, center black; spur very short; sepals 1 in. long, membranous and often clinging until the fr. is mature: follicles 3 or 4, villose. June, July. China. B.M. 5461. R.B. 1863:34.

9. *decorum*, Fisch. & Mey. St. slender and weak, ½–1½ ft. high, smooth or nearly so: lvs. few, bright green; upper ones small, 3–5-parted into narrow lobes; lower and radical ones somewhat reniform in outline and deeply 3–5-parted, lobes often differing widely: fls. in a loose raceme, or somewhat paniced; sepals blue, ½ in. long, equaling the spurs; upper petals at least tinged with yellow: follicles 3, thickish, glabrous. Spring. Calif. Intro. 1881 B.R. 26:64.

## DD. Petioles hardly dilating at the base.

## E. Upper petals never yellow.

10. *cashmerianum*, Royle. Plant pubescent, not very leafy: st. simple, erect, slender, 10–18 in. high: root-lvs. orbicular, 2–3 in. diam., 5–7-lobed, coarsely, acutely toothed and cut; petiole 5–8 in. long; sts.-lvs. short-petioled, 3–5-lobed, cut like the radical ones, all rather thick, and bright green: infl. corymbose, the branches rather spreading; fls. 2 in. long, deep azure-blue; spur broad, obtuse, inflated, decurved, little over half as long as sepals; upper petals almost black, 2-lobed, lateral ones greenish: follicles 3–5, hairy. July–Sept. Himalayas. B.M. 6189. Gt. 32:1105. Gn. 18:568. R.H. 1893, p. 259.—Hardy in Mass., and choice.

Var. *Walkeri*, Hook. St. very short, leafy, many-fl.; upper lvs. less lobed or almost entire, small, long-petioled: fls. very large, light blue with yellow petals. Suited to rockwork. B.M. 6830.

## EE. Upper petals yellow or striped with yellow.

11. *tricorné*, Michx. St. succulent, about 1 ft. high: lvs. 3–5-parted, with 3–5-cleft linear lobes; petioles smooth, hardly dilating at the base: fls. large, blue, rarely whitish; upper petals sometimes yellow, with blue

veins, lower ones white-bearded; sepals nearly equaling the spur: follicles 3-4, very long, becoming glabrous, strongly diverging; seeds smooth. May. Northern states. L.B.C. 4:306.—Very beautiful and much used. Best for rockwork. The foliage dies down in midsummer and the plant appears as if dead.

12. *Ménziesii*, DC. Plant sparingly pubescent: st. simple, slender,  $\frac{1}{2}$ -1 $\frac{1}{2}$  ft. high, few-ld.: lvs. small, 3-5-parted, the divisions mainly cleft into linear or lanceolate lobes; petioles hardly dilating at the base: fls. in simple, conical racemes; sepals blue, somewhat pubescent outside, nearly equaling the spurs in length; upper petals yellowish: follicles 3, pubescent, or sometimes glabrous; seeds black, winged on the outer angles. Apr.-June. On hills, Calif. and northward to Alaska. B.R. 1192.

13. *pauciflorum*, Nutt. Roots oblong or fusiform, fasciculate-tuberos: sts. slender, nearly glabrous,  $\frac{1}{2}$ -1 ft. high: lvs. small, parted into narrow, linear lobes; petioles not dilating at base: fls. and fr. similar to those of *D. Menziesii*, but on shorter pedicels. May, June. Colo. to Wash. and Calif. Intro. 1892.

cc. Height usually more than 1 $\frac{1}{2}$  ft.

d. Seeds wrinkled or smooth, not winged nor scaly.

e. Follicles always 3.

14. *altissimum*, Wall. Plant shaggy-hairy above: st. tall and slender, branched: lvs. palmately 5-parted, the divisions 3-lobed and toothed: bracts long-lanceolate: fls. blue or purple, in long, branching racemes; spur straight or slightly incurved, equaling the sepals; petals 2-lobed: follicles 3, erect; seeds not winged or scaly. Aug., Sept. Himalayas.

15. *exaltatum*, Ait. St. stout, 2-4 ft. high, smoothish: lvs. flat, nearly glabrous, deeply cleft into 3-7 wedge-shaped lobes, which are often trifid; petioles usually not dilated at the base: fls. blue, with yellow on the upper petals, medium in size, on long, crowded, erect, pyramidal racemes; sepals nearly equaling the spur in length: follicles 3, pubescent or smooth; seed-coats irregularly wrinkled. June-Aug. Borders of woods, Ala. to Minn.

16. *elatum*, Linn. (*D. alpinum*, Waldst. & Kit. *D. pyramidale*, Royle). BEE LARKSPUR. Glabrous, 2-6 ft. high: lvs. somewhat pubescent, 5-7-parted, part rather narrow, cut-lobed; upper lvs. 3-5-parted, petioles not dilated at the base: raceme much like *D. exaltatum* or more spike-like; fls. blue, with dark violet petals; sepals ovate, glabrous, nearly equaling the spurs: follicles 3; seeds transversely wrinkled, not scaly. June-Aug. B.R. 1963 (as *D. intermedium*). F.S. 12:1287. (var. *fl.-pl.*). R.H. 1859, p. 529; 1893, p. 258.—A polymorphous and complex species of Eu. It is probable that all or nearly all the plants sold here under this name should be called *D. exaltatum*, which is a closely allied species.

17. *grandiflorum*, Linn. (*D. sinense*, Fisch.). Figs. 1232, 1233. St. rather slender, 2-3 ft. high: lvs. rather small, many times parted into nearly distinct, narrow, linear lobes: fls. large, blue, varying to white, the spur and lower petals often violet, upper petals often yellow; spurs long and taper pointed: follicles 3, pubescent; seeds triangular, coats wrinkled, not scaly. Blooms in midsummer. Siberia. Intro. 1880. B.M. 1686. Gn. 46: 484. Var. *album*, Hort. Fls. pure white. Var. *albo-pleno*, Hort. Fls. double and pure white. Var. *flöre-pleno*, Hort. (var. *hybridum fl.-pl.*, Hort.). Fls. double, blue, very pretty. R.H. 1893, p. 259; 1895, p. 379 (same).—This group includes the most common and the most beautiful of the perennial delphiniums. *Grandiflorum* is also one of the most stately. Its striking foliage remains beautiful throughout the growing season. It is usually planted well back in the hardy border because of its height, smaller plants

being in front. They may be massed as close as 2 ft. or less but produce a fine effect when 4 ft. apart.

Var. *chinense*, Fisch. St. very slender, not much branched: lvs. and fls. like the type, but fls. more numerous. China. L.B.C. 1:71.—A favorite garden form. The double blue form has been known as *D. Brückii*, Hort.

EE. Follicles varying from 3-5.

18. *carolinianum*, Walt. (*D. azureum*, Michx. *D. virescens*, Nutt.). Plant somewhat pubescent: st.  $1\frac{1}{2}$ -2 $\frac{1}{2}$  ft. high, not much branched: lvs. 3-5-parted, the divisions 3-5-cleft into usually linear lobes: racemes spicate, usually many-flid.; fls. azure-blue, but varying to whitish or white; sepals often with a brownish spot: follicles 3-5, oblong, erect; seeds transversely wrinkled. July. N. C. to Ill., west and south. P.M. 16:258. Var. *album*, Hort. (var. *albidum*, Hort.). Sts. 2-3 ft. high: lvs. larger than the type and with border divisions: fls. creamy white.—The double form of this is not much used.

Var. *vimineum*, Gray. St. 2-4 ft. high, sometimes branched, broader-ld., looser-flid.: fls. violet or white. Texas. B.M. 3593. B.R. 1999 (as *D. azureum*).

19. *mesoleucum*, Link. St. 3 ft. high, pubescent above: lvs. 3-5-parted, the segms. wedge-shaped and deeply serrated; petioles somewhat dilated at the base: fls. blue, with pale yellow or whitish petals: seeds not seen. June. Nativity not known.

DD. Seeds winged.

E. Upper petals never yellow.

20. *trolliifolium*, Gray. St. 2-5 ft., leafy, often reclining: lvs. thinnish, large, often reniform at base, 3-7-parted; lobes wedge-shaped, incised: racemes in larger plants 1-2 ft. long and very loose; fls. blue, with upper petals white; spur and sepals each  $\frac{3}{4}$  in. long: follicles glabrous; seeds with thin wing or crown at the end. April. Moist grounds, Columbia River. Intro. 1881.

EE. Upper petals often yellow.

21. *simplex*, Douglas. St. nearly simple, 2-3 ft. high, soft-pubescent throughout: lvs. many-parted, into linear divisions and lobes: racemes dense, little branched; fls. pale blue, with upper petals yellow, lower petals white-bearded; sepals equaling the spur: follicles 3, pubescent; seeds dark, with margins white-winged. June. Mts. of Idaho and Ore. Intro. 1881.

22. *Nuttallii*, Gray (*D. columbianum*, Greene). St. erect, simple, nearly glabrous, leafy,  $1\frac{1}{2}$ -2 $\frac{1}{2}$  ft.: lvs. thinnish, 3-5-parted, parts divided into many linear-oblong lobes: racemes long, many-flid.; sepals deep blue, ovate, sparingly pubescent, shorter than the spur; petals blue or upper ones yellow, lower ones white-bearded: follicles 3, pubescent, rather erect; seeds thin, dark, with yellow wings. Summer. Low, open woods, Columbia River. Intro. 1892.

23. *scopulorum*, Gray. St. 2-5 ft., glabrous, at least below: lvs. 5-7-parted, the upper ones the more narrowly cleft; petioles dilating at the base: racemes simple, densely many-flid.; fls. blue or purple, rarely white, upper petals often yellow; spur  $\frac{1}{2}$  in. long, equaling the sepals: follicles 3, pubescent; seeds large-winged. Aug., Sept. Moist ground, west of Rockies.—A polymorphous species.

Var. *subalpinum*, Gray (*D. occidentale*, Wats.). A smaller plant, pubescent above: broader divisions of lvs., shorter racemes, larger and deeper-colored fls.: follicles glabrous. Wasatch Mts.

24. *cheilanthum*, Fisch. St. erect, simple or branched, 2-3 ft.: lvs. glabrous or slightly pubescent, 5-parted, the lobes pointed, sub-trifid, and somewhat toothed: fls. dark blue, the upper petals sometimes pale yellow, the lower ones inflexed, ovate, entire; spur

rather long, straight or somewhat curved; foliicles 3, either glabrous or pubescent; seeds 3-cornered, 3-winged, not scaly. June, July. Siberia. B.R. 473. J.F. 1, pl. 49. Gt. 13:253. P.M. 16:258 (as *D. magnificum*).

DDD. *Seeds scaly.*

25. *formosum*, Boiss. & Huet. Fig. 1234. St. strong, 2-3 ft., hairy below, rather glabrous above: lower lvs. 5-7-parted, long-petioled; upper ones 3-5-parted, short-petioled or sessile, all alternate: racemes many-fl.; fls. blue, with indigo margins; spur long, violet, bifid at the tip: foliicles 3, pubescent; seeds scaly. June, July. Asia Minor perhaps, but the origin of it is disputed. F.S. 12:1185. R.H. 1859, p. 528. G.Z. 1:144. H.F. 8:99.—The most permanent form for naturalizing, because it is so hardy. If given rich soil and good cult., it is one of the most effective for use in the permanent fl.-border. Var. *coelestinum*, Hort. Fls. light blue.

26. *Maackianum*, Regel. Erect, 3 ft. high, pubescent or glabrous, branched above: lvs. pubescent on both sides, base often truncate or reniform, 3-5-parted, the parts serrate; petioles dilated at the base: peduncles yellow-hairy, with the bracts often inserted above the base; fls. in loose panicles; sepals blue, half as long as the spurs; petals dark violet: foliicles often glabrous,  $\frac{3}{4}$  in. long; seeds small, distinctly scaly. July. Siberia.

27. *hybridum*, Steph. St. 3-4 ft., pubescent above: root somewhat bulbous: lvs. 5-many-parted; lobes linear; petioles dilated and sheathing at the base: racemes dense; fls. blue, lower limbs white-bearded; spur straight, longer than the sepals: foliicles 3, hairy; seeds ovate, with transverse scales. June-Aug. Mts. of Asia. R.H. 1893, p. 258; same cut in S.H. 2:282.—There are many double and semi-double varieties of this type. This is the tallest and most robust of the popular species of Delphinium. It will respond well to fertilizer and cult. When the clumps become large and strong they are usually set about 4 ft. apart. Young plants may be set 2 ft. apart and thinned a year or two later.

Var. *Bárlowii*, Paxt. Very large, semi-double fls., deep blue, with brownish center. A supposed hybrid with *D. grandiflorum*. B.R. 1944. Intro. 1892.

AAA. *Perennial, garden hybrids.*

28. *cultorum*, Voss (*D. hybridum*, Hort., not Steph.). The general mixed and more or less undefinable hybrid delphiniums, constituting some of the choicest garden and border plants of many colors, single, semi-double and double.

1234. *Delphinium formosum*. ( $\times \frac{1}{2}$ )

*D. carulescens*, Freyn. A fine Asiatic species, with single and double forms. P.M. 16:258.—*D. candidum*, Hemsl. A dwarf perennial: fls. pure white. Uganda. B.M. 8170.—*D. cardiopetalum*, DC., is a pretty annual, branching very low, the outer branches very short, giving a pyramidal form when covered with blue fls. R.H. 1893, p. 228.—*D. caucasicum*, C. A. Mey. (*D. speciosum* var. *caucasicum*, Huth.). Similar to *D. cashmerianum*.—*D. Davidii*, Franch. Hairy: lvs. 3-parted almost to the base: fls. light blue. China.—*D. divaricatum*, Ledeb. Allied to *D. consolida*, but taller, more branched, with smaller more abundant fls. Caucasus and Caspian region. R.H. 1912, p. 513.—*D. macrocentron*, Oliv. Perennial, hairy in nearly all parts: fls. blue and green or yellow and green. E. Trop. Afr. B. M. 8151.—*D. Moerhousii*, Hort. A garden hybrid.—*D. Pardonii*, Craib. Fls. blue in somewhat lax raceme. China.—*D. Ráryi*, Gray, is also listed in the trade, and is closely allied to *D. consolida*.—*D. Wheelerii* is listed in the trade and is doubtless a variety of *D. speciosum*, Bieb., from E. Asia. Many other species may be expected in the lists of collectors and fanciers.

K. C. DAVIS.

DEMAZÈRIA: *Desmazeria*.

DEMERARA ALMOND: *Terminalia*.

DÉNDRIUM: *Leiorhynchum*.

DENDROBIUM (*tree and life*; they are epiphytic). *Orchidaceæ*. Epiphytic orchids of great horticultural merit, grown in hothouses and greenhouses.

Pseudobulbs (sts.), tufted or arising at intervals from a creeping st. sometimes very short and thick, more commonly elongated and often thickened at or near the base, naked or leafy at time of flowering: fls. usually showy, rarely small, in terminal or lateral racemes which are long and lax or short and dense, sometimes of a few fls., or sometimes reduced to 1 or 2; sepals about equal, the dorsal free, the lateral adnate obliquely to the foot of the column, forming either a short sac-like or long spur-like foot or mentum; petals usually resembling the dorsal sepal, either broader or narrower; lip jointed or adnate to foot of column, 3-lobed or entire; pollinia 4.—A large genus of about 600 species, ranging from India and Ceylon to Austral., New Zeal., Japan, and the Pacific Isls., being especially numerous in the Malay Archipelago. There are numerous hybrids, artificially produced.

There are two well-marked sections in this genus for the guide of the cultivator, the evergreen and the deciduous. The first named should not be allowed to become dry at the roots at any period, or loss of vigor will result. Among these, also, are some that need warm-house treatment all the time, such as *D. Phalænopsis*, *D. bigibbum*, *D. Bensoniæ*, *D. Brymerianum*, *D. Dearei*, and others. There are, in fact, but few among the evergreen species that need a coolhouse, and of these *D. formosum*, *D. infundibulum* and its variety *Jamesianum* are conspicuous. Apart from these, the evergreen dendrobies should be kept in a warmhouse during winter where 60° F. may be maintained.—All the deciduous species (typified by *D. Nobile*, *D. Wardianum* and *D. Pierardii*) need a marked resting period, easily determined by the finishing up of the growth in autumn, and the swelling of the nodes for flowering in spring. When at rest, it does not hurt the plants to be subjected to a low temperature of 45°, and it may be done to retard plants for later blooming, allowing the day heat to be regulated by the sun, with plenty of ventilation on favorable days. After the pseudobulbs have flowered, they cease to be of value to the plants, and should be cut out; if there are portions that have not produced flower-buds, these may be used for propagation, cutting the pieces into lengths of several joints or nodes, and laying them on moss in a warm propagating-house or -case, when they will soon produce growths. The above also applies to the hybrids, now so numerous, that have been raised from the deciduous Indian species.—Another section that requires warmth in winter, and now very much grown for cut bloom, is represented by *D. Phalænopsis* and *D. bigibbum*. These are Australian, quite distinct in growth, and usually short-lived in cultivation. The flowers are produced freely for a

XXXV. *Dendrobium superbum* as grown in the American tropics.

few years, are very decorative, and the plants may be increased by taking off the young plants that often appear on the stems. These often can be grown on to strong flowering specimens, and thus the stock maintained. When wintered in a temperature less than 60°, the plants suffer, and great care is necessary at the time the young growths appear in spring to prevent damping off. Small pots or pans are best, and always keep the plants suspended near the sun and air. The evergreen tropical species, as *D. densiflorum*, *D. thysiflorum*, *D. aggregatum*, *D. Farmeri*, *D. moschatum*, *D. fimbriatum* and *D. Dalhousieanum*, also need warmth in winter and must not be dried severely during the resting-period or loss of vigor will ensue at the price of blooming. This section of the genus produces flowers from the old stems for many years. It frequently happens that growths made in India will bloom long after the plants have become established in gardens. It is thus unwise to cut old growths unless they become withered or dead. Enough water may be given to keep the plants plump, and the flowers will be produced freely in their season. In some species, growth begins before or at the time of bloom. This is usually a sign of extra vigor and should not be discouraged. The proper time to repot with all plants of flowering age, is when they begin to recuperate in early summer after the bloom is past; young roots will be seen pushing out at the base of the stems, and if this is anticipated by a week or two, the new material is soon taken to by the roots and no check is experienced. Good sound osmundine is the best material, always using small receptacles rather than large, and if larger than a 6-inch pot or pan, use perforated ones. The roots do not like exposure, but the material will be kept in a sweet healthy condition. Moss is best avoided in most cases; it often fails to grow, and is inimical to the welfare of the plants; when it does grow, it holds too much moisture about the roots. (E. O. Orpet.)

## GENERAL KEY TO SECTIONS.

A. *Lvs. equitant.* SECTION I. Species 1 and 2.

AA. *Lvs. not equitant.* SECTION II. Species 3-10.  
 B. *Lf.-sheaths black-hairy.*

BB. *Lf.-sheaths not black-hairy.* SECTION III. Species 11-14.  
 C. *Pseudobulbs not thickened at base.*  
 D. *Mentum or chin of fls. elongated.*

DD. *Mentum or chin of fls. short (rather long in D. ramosum).*  
 E. *Fls. usually in pairs, rarely 1 or 3 or more.*  
 F. *The pseudobulbs leafless at flowering time.* SECTION IV. Species 15-44

FF. *The pseudobulbs leafy at flowering time.* SECTION V. Species 45-55.

EE. *Fls. in 3- to many-fl. racemes (single in D. Jenkinsii).*  
 F. *The pseudobulbs 1-lvd., short, fusiform.* SECTION VI. Species 56 and 57.

FF. *The pseudobulbs several-lvd.*  
 G. *Racemes very short, glomerate.* SECTION VII. Species 58.

GG. *Racemes usually long, not glomerate.*  
 H. *Sepals and petals hairy externally; lateral lobes larger than middle lobe of lip.* SECTION VIII. Species 59.

HH. *Sepals and petals glabrous externally.*  
 I. *Pseudobulbs gradually attenuated from a thick bulbous base.* SECTION IX. Species 60.

II. *Pseudobulbs not bulbous at base.*  
 J. *Fls., at least the lip, purple or red.* SECTION X. Species 61-63.

JJ. *Fls. white or yellow.* SECTION XI. Species 64-75.

CC. *Pseudobulbs fusiform-thickened above base, attenuated beyond.* SECTION XII. Species 76.

## SECTION I.

A. *Pseudobulbs leafy at base, naked above.* 1. **Macfarlanei**  
 AA. *Pseudobulbs leafy throughout.*..... 2. **anceps**

1. **Macfarlanei**, Reichb. Pseudobulbs erect, nearly cylindric, up to 9 in. tall, 2-3-lvd.: lvs. 3-4 in. long: racemes 8-15-fl.; fls. 4-5 in. across, white, except the purple markings on lateral and middle lobes of lip. New Guinea.

2. **anceps**, Lindl. Pseudobulbs tufted, compressed, 5-8 in. long: lvs. up to 3 in. long, fleshy, laterally compressed: fls. axillary, solitary or in very short racemes, lemon-yellow at maturity. Trop. Himalayas. B.R. 1239. B.M. 3608 and L.B.C. 19:1895 (as *Aporum anceps*).

## SECTION II.

- A. *Raceme 1-2-, rarely 3-fld.*  
 B. *Mentum of fls. very short; sepals and petals green, yellow-margined.* . . . . 3. *cruentum*  
 BB. *Mentum of fls. long, extinguisher-shaped.*  
 C. *Sepals and petals white, not keeled.*  
 D. *Fls. 1½-2 in. across; lateral lobes of lip manifest.*  
 E. *Middle lobe yellow, reflexed; lateral lobes yellowish green.* 4. *scabrilingue*  
 EE. *Middle lobe white, yellow-marked, fimbriate.* . . . . 5. *longicornu*  
 DD. *Fls. 3 in. across; lateral lobes of lip indistinct.* . . . . 6. *infundibulum*  
 CC. *Sepals yellowish white, keeled.* . . . . 7. *cariniferum*  
 AA. *Raceme 3-8-fld.*  
 B. *Fls. yellow.* . . . . 8. *Lowii*  
 BB. *Fls. white.*  
 C. *Petals broad, oval or obovate.* . . . . 9. *formosum*  
 CC. *Petals oblong-lanceolate, narrow.* . . . . 10. *draconis*

3. *cruentum*, Reichb. Pseudobulbs erect, 10-12 in. tall; fls. 1½-2 in. across; sepals triangular-ovate, keeled; petals linear; lip 3-lobed, the lateral lobes scarlet, the middle lobe pale green, red-margined. Malay Penins. G.C. III. 18:91.

4. *scabrilingue*, Lindl. Pseudobulbs erect, 8-14 in. tall; fls. about 1½ in. across; sepals and petals similar, ovate-lanceolate, white; lip 3-lobed, the lateral lobes yellow-green, the middle lobe reflexed, yellow with orange-yellow lines. Burma. B.M. 5515 (as *D. hedyosmum*).

1235. *Dendrobium Dearei*.  
(×½)

5. *longicornu*, Lindl. Pseudobulbs 8-14 in. tall, slender; fls. 2-3 in. across, white except a central orange or yellow band on lip; sepals and petals similar, elliptic-oblong; lip fimbriate; spur slender. Burma. B.R. 1315.

6. *infundibulum*, Lindl. Pseudobulbs up to 2 ft. long, cylindric, slender; fls. about 3 in. across, white except the yellow blotch on the lip; sepals oblong-elliptic, less than half as broad as the nearly rhomboid petals; lip resembling a wide-mouthed funnel. Burma. B.M. 5446. I.H. 21:172. C.O. 6. Var. *Jamesianum*, Hort. (*D. Jamesianum*, Reichb.). Pseudobulbs stouter and stiffer; lateral lobes of lip roughened on the inner surface; disk cinnabar. Gn. W. 9:485.

7. *cariniferum*, Reichb. Pseudobulbs 6-10 in. tall, nearly cylindric; fls. about 1½ in. across; sepals yellowish white, fading white, narrower than the ovate white petals; lip 3-lobed, the triangular lateral lobes red-

orange, the middle lobe hairy, red-orange at the base, the front part white or pale orange; spur long, obtuse. Burma.

8. *Lowii*, Lindl. Pseudobulbs 8-15 in. tall, slender; fls. 1½-2 in. across, buff-yellow; sepals narrower than the undulate petals; lip distinctly 3-lobed, the lateral lobes tipped with red, the oblong middle lobe reflexed, marked with 6 lines of red hairs. Borneo. B.M. 5303. F.S. 23:2395. C.O. 30.

9. *formosum*, Roxbg. Pseudobulbs up to 1½ ft. tall, cylindric; fls. 3-4 in. across, white except the yellow mark on lip; sepals oblong-elliptic, about half as broad as the obovate petals; lip retuse, erose. Khasia Hills. B.R. 25:64. F.S. 3:226. P.M. 6:49. C.O. 8. O.R. 15: frontispiece. Var. *giganteum*, Hort. Fls. 4-5 in. across. G.C. III. 24:471. Gng. 1:118-9. F.E. 10:1240. F.S. 16:1633-4. G. 25:385.

10. *draconis*, Reichb. Pseudobulbs up to 1½ ft. tall; fls. about 1½ in. across, white except for some orange-red stripes at base of lip; sepals narrower than the petals; lip 3-lobed, the lateral lobes small, the oblong-oval middle lobe crisped and minutely toothed. Burma. B.M. 5459 (as *D. eburneum*).

## SECTION III.

- A. *Raceme secund.* . . . . 11. *secundum*  
 AA. *Raceme not secund.*  
 B. *Bracts small; racemes not capitate.*  
 C. *Fls. rosy purple, about 1 in. across.* . . . . 12. *cumulatum*  
 CC. *Fls. white, about 2½ in. across.* . . . . 13. *Dearei*  
 BB. *Bracts large, colored; racemes capitate* 14. *Bullenianum*

11. *secundum*, Wall. Pseudobulbs up to 2 ft. tall, cylindric; fls. narrow, less than 1 in. long, rosy purple, on one side of the raceme; lip with an apical orange blotch. Sumatra. B.R. 1291. B.M. 4352. C.O. 35. Var. *niveum*, Hort. Fls. white.

12. *cumulatum*, Lindl. Pseudobulbs up to 2 ft. long, pendulous; fls. rosy purple, in short racemes with a purple axis; sepals and petals similar, oblong; lip oblong-obovate; spur obtuse, slightly curved. Burma. B.M. 5703.

13. *Dearei*, Reichb. Fig. 1235. Pseudobulbs up to 3 ft. long; fls. white, 2-2½ in. across, in 5-7-fld. racemes; sepals lanceolate, acuminate, about one-third as broad as the oval petals; lip oblong, obscurely 3-lobed, a pale yellowish green band across the middle; spur funnel-shaped, elongated. Philippines. V.O. 3:37. G.W. 1:225. O. 1912:18. C.O. 36.

14. *Bullenianum*, Reichb. f. (*D. salaccense*, Hort., not Lindl. *D. erythroxanthum*, Reichb. f.). Pseudobulbs 10-18 in. tall; racemes densely fld.; fls. yellow, striped with purple; dorsal sepal and petals oblong; lateral sepals oblong, acute, about as long as the obtuse spur; lip oblong, from a long linear base, acute. Philippines.

## SECTION IV.

- A. *Sepals and petals not yellow.*  
 B. *Lip deeply fimbriate.* . . . . 15. *Devonianum*  
 BB. *Lip entire or minutely fimbriate.*  
 C. *Nodes of pseudobulb much thickened.*  
 D. *Pseudobulbs thick.*  
 E. *Internodes abruptly depressed-globose, thickened at apex.* . . . . 16. *pendulum*  
 EE. *Internodes gradually thickened toward apex.*  
 F. *Front lobe of lip ovate, reflexed, purple.* . . . . 17. *Linawianum*  
 FF. *Front lobe of lip orbicular-ovate, yellow.* . . . . 18. *Findlayanum*  
 DD. *Pseudobulbs wand-like, slender.* . . . . 19. *Falconeri*  
 CC. *Nodes not thickened, or but slightly so.*  
 D. *Internodes usually more than 5 times longer than broad.*

- E. *Lip curved like a trumpet; sepals and petals purple*....20. *lituiflorum*  
 EE. *Lip not curved.*  
 F. *Fls. white*.....21. *monile*.  
 FF. *Fls. with sepals and petals white, tips colored.*  
 G. *Throat of lip yellow.*  
 H. *Middle lobe violet, white-margined*.....22. *amœnum*  
 HH. *Middle lobe yellow, tip rose*.....23. *crystallinum*  
 GG. *Throat of lip purple*.....24. *transparens*  
 FFF. *Fls. with sepals and petals mauve, lip primrose*.....25. *Pierardii*  
 DD. *Internodes usually less than 5 times longer than broad.*  
 E. *Fls. 2½ in. across or less.*  
 F. *Color violet-purple*.....26. *Parishii*  
 FF. *Color white or lilac.*  
 G. *Lip primrose-yellow; sepals and petals lilac*.....27. *primulinum*  
 GG. *Lip with ground color white, a large light or dark yellow blotch in center.*  
 H. *Blotch not marked; base plaited*.....28. *crepidatum*  
 HH. *Blotch marked.*  
 I. *With 2 basal purple spots*.....29. *Bensoniæ*  
 II. *With reddish orange lines.*  
 J. *Shape of lip obtuse; blotch light yellow*.....30. *cretaceum*  
 JJ. *Shape of lip acute; blotch deep yellow*.....31. *gratiosissimum*  
 EE. *Fls. exceeding 2½ in. across.*  
 F. *Ground-color of sepals and petals white.*  
 G. *Throat deep purple*.....32. *nobile*  
 GG. *Throat yellow, with 2 purple spots*.....33. *Wardianum*  
 FF. *Ground-color of sepals and petals rose.*  
 G. *Front lobe of lip rose, the throat yellow*.....34. *regium*  
 GG. *Front lobe of lip white-margined, the throat with 2 dark spots*.....35. *rhodopterygium*  
 AA. *Sepals and petals yellow.*  
 B. *Lip deeply pectinate-fringed*.....36. *Brymerianum*  
 BB. *Lip not fringed.*  
 C. *Disk pilose; 2 large purple fringed spots at base of lip*.....37. *Dalhousieanum*  
 CC. *Disk not pilose, nor with fringed spots*  
 D. *The lip slipper-shaped*.....38. *moschatum*  
 DD. *The lip not slipper-shaped.*  
 E. *Unicolored, yellow.*  
 F. *Shape of sepals and petals acute; lip minutely serrate* 39. *dixanthum*  
 FF. *Shape of sepals and petals obtuse; lip fimbriate*.....40. *fimbriatum*  
 EE. *Bi-colored, yellow with purple markings.*  
 F. *Apex of lip acute; sepals and petals pale yellow.*  
 G. *Front lobe nearly rhomboid, cream-margined*...41. *Aphrodite*  
 GG. *Front lobe ovate, red-lined, the apex recurved*.....42. *aureum*  
 FF. *Apex of lip rounded; sepals and petals rich yellow.*  
 G. *Fls. 2½ in. or more across; lip with a single large spot.*  
 H. *Lip serrate or shortly fimbriate; floral bracts large*.....43. *clavatum*  
 HH. *Lip fimbriate, the divisions branched; floral bracts small*.....40. *var. oculatum*

15. *Devoniænum*, Paxt. Pseudobulbs up to 3 ft. long, round, pendulous: fls. single or in pairs, about 2 in. across; sepals and petals white tinted amethyst at the apex, the sepals about half as broad as petals, lanceolate, the petals ovate, acute, ciliate; lip white, fringed, the apex purple, and 2 orange blotches in the throat. N. India to S. China. B.M. 4429. J.H. III. 34:197; 52:317. G.C. III. 7:680. C.O. 23. O.R. 4:177; 12:152.

16. *péndulum*, Roxbg. Pseudobulbs abruptly swollen at the nodes, up to 2 ft. long, somewhat pendulous: fls. solitary or 2 or 3 together, 2-2½ in. long; sepals and petals white, purple-tipped, acute, the petals broader than sepals; lip white, ciliate, pubescent on upper surface, the center yellow, the front margin purple. Moulmein. B.M. 5766 (as *D. crassinode*). C.O. 19. O.R. 2:177; 8:177. Var. *Barberiænum*, Hort. Fls. brighter, the apical spots larger and deeper.

17. *Linawiænum*, Reichb. (*D. moniliforme*, Lindl., not Swartz). Pseudobulbs with internodes gradually thickened toward apex, up to 1½ ft. long, clavate: fls. in pairs or 3's, about 2 in. across; sepals and petals rosy purple above, white below, the sepals half as broad as petals; lip obscurely 3-lobed, small, the front lobe purple, the lower part white with 2 purple spots on disk. China and Japan. B. M. 4153. P.M. 3:77.

18. *Findlayænum*, Par. & Reichb. Pseudobulbs with internodes gradually thickened toward apex, up to 1½ ft. long: fls. in pairs, 2-3 in. across; sepals and petals pale lilac, the sepals much narrower than the petals; lip yellow, white-margined. Burma. B.M. 6438. Gn. 49:446. G.M. 44:373 (var. *roseum*). O.R. 8:169.

19. *Falconeri*, Hook. Pseudobulbs slender, up to 1½ ft. long: fls. solitary, 2-3 in. across; sepals and petals white, purple-tipped, the former tinged with pale rose, the petals broader than sepals; lip obscurely 3-lobed, the throat deep purple, with an orange spot on each side and a white band in front, the acute apex purple. N. India. B.M. 4944. I.H. 23:243. F.M. 1876:226. G.Z. 31:145. Var. *gigantæum*, Hort. Pseudobulbs larger: fls. larger and lasting longer.

20. *lituiflorum*, Lindl. Pseudobulbs up to 2 ft. long, pendulous: fls. in pairs, rarely more, 2-2½ in. across; sepals and petals amethyst, the former paler at base, the latter the more richly colored, the sepals much narrower than the petals; lip curved like a trumpet, the opening turned up, the throat purple, surrounded by a white zone, the margin purple. Burma. B.M. 6050. Var. *candidum*, Reichb. Fls. larger, the sepals and petals white, the lip sulfur-yellow. Var. *Freëmanii*, Hort. Sepals and petals deeper in color, the lip with a sulfur-yellow zone.

21. *monile*, Kränzl (*D. japonicum*, Lindl.). Pseudobulbs up to 1 ft. long, slender-clavate: fls. solitary or in pairs, fragrant, white except for a few purple spots on the lip; sepals narrower than petals, both acute; lip acuminate, reflexed at apex. S. Japan. B.M. 5482.

22. *amœnum*, Lindl. Pseudobulbs up to 1½ ft. long, slender: fls. solitary, or sometimes in 2's or 3's, about 2 in. across; sepals and petals white, amethyst-tipped; lip with the front lobe ovate, amethyst margined with white. Nepal. B.M. 6199. G.C. II. 16:625.

23. *crystallinum*, Reichb. f. Pseudobulbs up to 2 ft. long, somewhat pendulous: fls. solitary, or sometimes in 2's or 3's, about 2 in. across; sepals and petals white, tipped with amethyst, or this sometimes lacking in the sepals which are much narrower than the petals; lip with a yellow middle lobe margined white. Burma. B.M. 6319. Var. *álbens*, Hort. Sepals and petals pure white; lip rich yellow tipped with white.

24. *transparens*, Wall. Pseudobulbs up to 20 in. long, slender: fls. in pairs or 3's, about 1½ in. across, white, the sepals, petals and lip tipped pale mauve; sepals lanceolate; petals oblong-elliptic; lip recurved

at the obtuse apex, the disk with a large purple spot. India. B.M. 4663. J.F. 1:68. C.O. 27.

25. *Pierárdii*, Roxbg. (*D. cucullatum*, R. Br.). Pseudobulbs up to 3 ft. long, slender, pendulous: fls. commonly in pairs, up to 2 in. across; sepals and petals pale rosy mauve, acute, the sepals lanceolate, much narrower than the elliptic-oblong petals; lip obscurely 3-lobed, pale primrose-yellow, pubescent on the upper surface, purple-streaked at base. India. B.R. 548 (as *D. cucullatum*); 1756. Gn. 55, p. 405. F.S. 9:955. L.B.C. 8:750. C.O. pl. 26. B.M. 2242 (as *D. cucullatum*); 2584. Var. *latifolium*, Hort. Lvs. broader.

26. *Párishii*, Reichb. f. Pseudobulbs up to 15 in. long, curved, rather stout: fls. solitary, or in 2's or 3's, amethyst-purple with 2 maroon spots on each side of the throat of lip; sepals oblong-lanceolate, narrower than the oval-oblong petals; lip downy, apiculate. Moulmein. B.M. 5488.

27. *primulinum*, Lindl. Pseudobulbs up to 20 in. long, erect or nearly so, rather stout: fls. solitary or in pairs, 2-3 in. across; sepals and petals pale mauve-lilac, oblong, obtuse; lip pale primrose-yellow, purple-streaked at base, the middle lobe very broad. Nepal and Sikkim. Gt. 1861:326. J.H. III. 50:377. B.M. 5003 (as *D. nobile*, var.). Var. *giganteum*, Hort. Pseudobulbs pendulous, more slender: fls. larger, the lip sometimes veined with pale rose.

28. *crepidatum*, Lindl. Pseudobulbs up to 1½ ft. long, nearly erect, rather stout, longitudinally marked with white lines: fls. in 2's or 3's, about 1½ in. across; sepals and petals white, tinted lilac, obtuse, the sepals oblong, narrower than the petals; lip white tinted lilac, sometimes downy, the front lobe obtuse or retuse, the middle orange-yellow. Assam. B.M. 4993, 5011. C.O. 40. Var. *roseum*, Hort. Fls. darker. Var. *album*, Hort. Fls. white.

29. *Bénsoniæ*, Reichb. f. (*D. Dartoisianum*, De Wild. *D. signatum*, Reichb. f.). Pseudobulbs up to 32 in. long, erect, rather slender: fls. solitary, or in 2's or 3's, 2-2½ in. across, white, the disk of the lip yellow with 2 maroon spots; sepals oblong, obtuse, much narrower than the petals; lip with the front lobe orbicular, denticulate, downy on the upper surface. British Burma. B.M. 5679, 8352. O.R. 11:241; 16:68. F.M. 355. Var. *majus*, Hort. Fls. larger.

30. *cretaceum*, Lindl. Pseudobulbs up to 15 in. long, rather stout, curved, pendulous: fls. solitary, about 1½ in. across, cream-white, with a large light yellow spot on lip streaked with orange-red; sepals and petals lanceolate, obtuse; lip with the front lobe orbicular-ovate, obtuse, downy. Khasia Hills. B.R. 33:62. B.M. 4686. F.S. 8:818. J.F. 4:344.

31. *gratiosissimum*, Reichb. f. (*D. Buxallii*, Reichb. f. *D. Bullerianum*, Batem.). Pseudobulbs up to 1½ ft. long, somewhat thickened from a slender base: fls. in 2's and 3's, 2-2½ in. across, white, the sepals, petals and lip tipped with rose-purple; sepals oblong-lanceolate, narrower than the ovate-lanceolate petals; lip with the front lobe broadly ovate, acute, a large yellow orange-streaked blotch in the center. Burma and Moulmein. B.M. 5652. F.M. 315. G.W. 1, p. 227.

32. *nobile*, Lindl. Fig. 1236. Pseudobulbs up to 2 ft. long, erect or nearly so, tufted, nearly round: fls. in 2's or 3's, 2½-3 in. across; sepals and petals white, the upper portion, varying in extent, amethyst-purple, the sepals ligulate, the petals broader, oblong-oval, wavy-margined; lip with a broad nearly orbicular blade, downy, a large rich maroon spot in the center, inclosed by a cream-white zone, the apex amethyst-purple. Himalayas to China. P.M. 7:7. C.O. 1. O.R. 5:209; 9:73. G.M. 47:425. J.H. III. 48:511; 56:511. Var. *albiflorum*, Hort. Fls. white, with a black-purple spot on the lip. O.R. 2:113; 9:73. Var. *album*, Hort. Fls. pure white. Var. *Amesiæ*, Hort. Similar to the preceding,

but fls. larger. Var. *Armstrongiæ*, Hort. Sepals and petals pure white, of great size; lip very dark maroon-purple. Var. *Ashworthianum*, Hort. Fls. pure white, except the green mouth of the lip. Var. *Ballianum*, O'Brien. Sepals and petals white; lip yellowish white or white with 2 crimson spots. C.O. 1 b. Var. *cærulescens*, Reichb. (*D. cærulescens*, Lindl.). Shorter and more slender pseudobulbs: fls. smaller and of a deeper color, and the lip-blade more oval. Var. *Colmanianum*, Hort. A large, pure white variety with a sulfur-yellow disk to the lip. Var. *Cooksonianum*, Reichb. f. Petals concave, approaching the lip in form, erect, with a large basal maroon blotch. C.O. 1a. O.R. 2:113; 9:73. Var. *elegans*, Hort. Fls. larger and more symmetrical; petals broader, the base white; a pale sulfur-yellow zone inclosing the maroon spot on lip, which has a rose-purple apex. Var. *formosanum*, Reichb. f. Pseudobulbs somewhat longer,

1236. *Dendrobium nobile*. (×¼)

pendulous: fls. with longer pedicels, the tips of the petals and lip only purple, the mouth and mentum green. Var. *jaspidium*, Hort. Fls. very showy; apex of segms. red variegated with purple. Var. *murrhianum*, Hort. Like var. *Ballianum*, but finer: sepals and petals slightly tinged violet; disk rich violet, finely veined with rose-violet. Var. *nobilius*, Reichb. f. Fls. larger, the sepals and petals, except at the base, deep purple; lip large, rose-tipped, deep purple in the mouth. C.O. 1c. G.M. 46:193. O.R. 2:113; 9:73. Var. *Owenianum*, Hort. Var. *Rajah*, Hort. Like var. *albiflorum*, but sepals and petals broader and flushed with delicate pink. Var. *Rothwellianum*, Hort. Var. *Sanderianum*, Reichb. f. Resembles var. *nobilius* but fls. smaller, the color more intense, the sepals and petals broader, the lip with a large black purple spot, the surrounding white zone larger. R. 58. O.R. 2:113; 9:73. Var. *Schneiderianum*, Reichb. f. Lip suffused with yellow, and with a deep purple spot. Var. *Schroederianum*, Hort. Larger fls. with broader segms., the sepals and petals white, sometimes tipped with amethyst; lip with an almost black spot, bordered with pale yellow, passing into white. Var. *summitense*, Hort. Var. *Tollianum*, Reichb. f. Pedicels twisted, the

fls. therefore appearing inverted; fls. not fully opening. Var. *virginale*, Hort. Fls. pure white, except a pale primrose tinge on the lip. G.C. III. 35:357. G.M. 52:394. O.R. 5:145; 8:121.

33. *Wardi anum*, Warner. Pseudobulbs up to 3 ft. long, round, pendulous: fls. in 2's or 3's, 3-4 in. across; sepals and petals white, oblong, usually tipped with amethyst, about half as wide as the white oval petals which are amethyst-tipped; lip white with an amethyst apical blotch, the throat yellow, with a maroon spot on each side. B.M. 5058. I.H. 24:277. F.R. 1:231. Gn. 47, p. 84. R.B. 23:25. J.H. III. 30:454; 32:237; 42:211. G.M. 45:744. C.O. 5. O.R. 2:177; 8:177; 9:frontispiece. R. 9. Var. *album*, Williams. Fls. white, except the yellow throat with 2 purple-crimson spots. C.O. 5a. Var. *aureum*, Hort. Sepals and petals light yellow. Var. *Fowleri*, Hort. Lateral sepals with yellow markings and purple blotch as in the lip. G.C. III. 31:125. Var. *xantholeucum*, Hort. Fls. pure white, with a large orange-yellow disk to the lip.

34. *regium*, Prain. Pseudobulbs up to 1 ft. long, cylindric: fls. in 2's or 3's, nearly 3 in. across; sepals and petals purple-rose, darker veined, obtuse, the sepals oblong, narrower than the ovate or oval petals; lip with the limb nearly orbicular, purple-rose, the throat yellow, surrounded by a cream-white zone. India. B.M. 8003. G.C. III. 42:122.

35. *rhodopterigium*, Reichb. f. Pseudobulbs up to 2 ft. long, erect, cylindric: fls. about 2½ in. across; sepals and petals rosy purple, mottled with white; sepals oblong-lanceolate; petals oblong-ovate; lip crimson-purple, striated, white-margined, denticulate, with a central pale longitudinal band. Burma and Moulmein.

36. *Brymerianum*, Reichb. f. Pseudobulbs up to 2 ft. long, rather stout, a little enlarged at the middle: fls. solitary or in few-fl. racemes, about 3 in. across, golden yellow; sepals broadly lanceolate, acutish, a little broader than the linear-oblong obtuse petals; lip with lateral lobes erect, fimbriated with short ciliate flexuous divisions, the middle lobe ovate, fimbriate with very long branched ciliate divisions; disk papillose. Burma. B.M. 6383. A.F. 6:609. G.C. II. 11:475; 16:689. F.M. n. s. 459. R. 92. Lind. 4:183. G.Z. 30:121. O.R. 12:249; 16:24.

37. *Dalhousie anum*, Wall. Pseudobulbs 2-4 ft. long, round, rather slender: racemes pendulous, 6-10-fl.; fls. 4-5 in. across; sepals and petals pale yellow, tinted and veined with rose, the sepals ovate-lanceolate, much narrower than the ovate petals; lip concave, hairy in front, with 2 large fringed purple spots near the base. Burma. B.R. 32:10. I.H. 28:423. Gn. 48:222. G.C. III. 21:157. P.M. 11:145. F.S. 7:698. C.O. 7. Var. *luteum*, Hort. Fls. tinted sulfur-yellow, with crimson disks at base of lip.

38. *moschatum*, Wall. Pseudobulbs up to 6 ft. tall, cylindric: racemes 5-15-fl.; fls. 3-4 in. across, faintly fragrant of musk; sepals and petals pale yellow, tinted pale rose at apex, veined and reticulated, the sepals much narrower than petals; lip slipper-shaped, pale yellow, with 2 large maroon spots encircled with orange, the front part hairy. India. B.M. 3837. B.R. 1779 (as *D. cupreum*). P.M. 2:241. Var. *Calceolaria*, Veitch Man. Fls. smaller, orange-yellow, with deeper veins and reticulation, and deeper spots on lip. C.O. 13.

39. *dixanthum*, Reichb. f. Pseudobulbs up to 3 ft. tall, erect, somewhat clavate: racemes 2-6-fl.; fls. yellow, with an orange mark on lip; sepals and petals acute, the former lanceolate, narrower than the oblong, serrulate petals; lip serrulate, the blade nearly orbicular. Moulmein and Tenasserim. B.M. 5564.

40. *fimbriatum*, Hook. Pseudobulbs 3-5 ft. tall, cylindric: racemes 6-12-fl., pendulous; fls. 2-3 in. across; sepals and petals bright orange-yellow, the former oblong-elliptic, narrower than the oblong-oval,

ciliate petals; lip bright yellow, with an orange spot on the orbicular fimbriate blade, Nepal. P.M. 2:172. J.F. 3:314. G.C. III. 25:305. C.O. 9. Var. *oculatum*, Hook. Pseudobulbs shorter, more slender, the smaller fls. with a maroon spot on the lip. B.M. 4160. I.H. 1:15. C.O. 9a. P.M. 6:169 (as *D. Paxtoni*). F.S. 7:725 (as *D. Paxtoni*).

41. *Aphrodite*, Reichb. f. (*D. noctatum*, Lindl.). Pseudobulbs up to 1 ft. long, slender, branched: fls. solitary or in pairs, 2-3 in. across; sepals and petals cream-colored, the former lanceolate, narrower than the ovate petals; lip cream-colored, with a large saffron-yellow spot in the middle, and 2 maroon spots at base, the front lobe nearly rhomboid, acute. Moulmein and Tenasserim. B.M. 5470. F.S. 15:1582.

42. *aureum*, Wall. (*D. heterocarpum*, Wall. *D. rhomboideum*, Lindl.). Pseudobulbs up to 1½ ft. tall, erect, somewhat clavate: fls. in 2's and 3's, fragrant, 2-2½ in. across; sepals and petals cream-colored, acute, the former oblong-lanceolate, a little narrower than the oblong-ovate petals; lip yellow, streaked with reddish purple, the front lobe ovate, acuminate, recurved, the disk velvety. Trop. Himalayas to Philippines. B.M. 4708. F.S. 8:842. P.M. 14, p. 68, desc. J.F. 4:386. C.O. 10. R. 63. B.R. 29:17. J.H. III. 52:405; 57:3. O.R. 8:41, 169. Var. *sulphureum*, Hort. Fls. sulfur-yellow, with the usual orange-colored markings.

43. *clavatum*, Wall. Pseudobulbs up to 3 ft. long, cylindric, pendulous: racemes 4-6-fl.; fls. 2-3 in. across; sepals and petals orange-yellow, the former oval-oblong, about half as wide as the nearly orbicular petals; lip bright yellow, with a maroon blotch in center, the front lobe orbicular, denticulate, the upper surface pubescent. Trop. Himalayas to S. China. B.M. 6993.

44. *Gibsonii*, Lindl. (*D. fuscatum*, Lindl.). Pseudobulbs up to 3 ft. tall, a little enlarged in the middle, slender: racemes 5-10-fl., pendulous; fls. about 2 in. across, golden yellow, with 2 maroon spots on the lip; sepals and petals oval-oblong, obtuse, about the same width; lip with the limb a little broader than long, rounded at apex, fimbriate, villous on the upper surface. Trop. Himalayas to S. China and Java. P.M. 5:169. B.M. 6226.

## SECTION V.

- A. Sepals and petals white.
- B. Without markings.
  - c. Middle lobe of lip quadrate, emarginate, undulate; spur short, sacate.....45. *lasioglossum*
  - cc. Middle lobe of lip triangular, acute, ciliate; spur long, conic.....46. *aqueum*
- BB. With purple or mauve at apex.....32. *nobile*
- AA. Sepals and petals purple, mauve or lilac.
  - B. Base of lip inclosing column; sepals and petals widely spreading.
    - c. Lip fringed; disk yellow.....47. *Loddigesii*
    - cc. Lip denticulate; throat deep purple 48. *superbum*
  - BB. Base of lip not inclosing column; sepals and petals ascending.....49. *MacCarthyæ*
- AAA. Sepals and petals yellow.
  - B. Color pale.
    - c. Fls. buff-yellow; lip clawed, with 2 purple spots.....50. *albo-san-guineum*
    - cc. Fls. primrose-yellow; lip at base convolute around column.
      - d. Middle lobe of lip oblong, emarginate; petals larger than sepals 51. *luteolum*
      - dd. Middle lobe of lip nearly orbicular, reflexed, much undulated.. 52. *ramosum*
  - BB. Color bright.
    - c. Lip with a single large maroon blotch.....53. *ochreatum*
    - cc. Lip with 2 purple spots.
      - d. Margin of lip denticulate.....54. *chrysanthum*
      - dd. Margin of lip fimbriate, the divisions long and bearded... 55. *Hookerianum*

45. *lasioglóssum*, Reichb. f. Pseudobulbs up to  $1\frac{1}{2}$  ft. long, slender, pendulous, a little enlarged at the middle: fls. in 2's or 3's, white, except the reddish lines on the side lobes of the lip; sepals ovate, a little narrower than the petals; lip 3-lobed, the lateral lobes rounded, denticulate, the middle lobe nearly quadrate, undulate, reflexed, the disk with a tuft of orange-yellow hairs. Burma. B.M. 5825.

46. *aqueum*, Lindl. (*D. album*, Wight.). Pseudobulbs up to 2 ft. long, rather stout, decumbent: fls. about 2 in. across, solitary or in pairs, cream-white, except a yellow spot on the lip; sepals and petals similar, broadly ovate, acute; lip obscurely 3-lobed, the middle lobe triangular, deflexed, ciliate, the upper surface pubescent. Neilgherry Hills. B.R. 29:54. B.M. 4640. J.F. 3:262.

47. *Lóddigesii*, Rolfe (*D. pulchellum*, Lodd., not Roxbg. *D. Seidelianum*, Reichb. f.). Dwarf: pseudobulbs 3-4 in. long: fls. solitary, about  $1\frac{1}{2}$  in. across; sepals and petals lilac, the sepals oblong, much narrower than the ovate petals; lip orbicular fringed, the center orange-yellow, the margin pale lilac. China. L.B.C. 20:1935. B.M. 5037.

48. *supérbum*, Reichb. f. (*D. macrophyllum*, Lindl. Plate XXXV. *D. Scottéchinii*, Hook. *D. macranthum*, Hook.). Pseudobulbs up to 3 or 4 ft. long, cylindric, pendulous: fls. in pairs, 3-5 in. across, with the odor of rhubarb; sepals and petals purple-lilac, acute, the former oblong-lanceolate, about half as wide as the oblong-ovate petals; lip with the tube a deep red-purple, this color appearing as 2 large spots in the throat, the front lobe acuminate, reflexed, denticulate, the upper surface pubescent. Philippines. B.M. 3970. C.O. 20. P.M. 8:97. F.S. 8:757. O.R. 14:78; 20:144. Var. *anósmum*, Reichb. f. (*D. anósmum*, Lindl. *D. macrophyllum* Dayanum, Hort.). Pseudobulbs shorter: fls. usually solitary, nearly odorless, smaller, the sepals and petals shorter and broader. Lind. 6:264. P.M. 15:97. Var. *gigantéum*, Reichb. f. Fls. larger. Var. *Huttonii*, Reichb. f. Fls. white, except the base of the lip and 2 spots on it which are purple. Malay Archipelago. Var. *Richardii*, Hort. Medium-sized very fleshy fls. set on long bristled pedicels.

49. *MacCárthiaë*, Thwaites. Pseudobulbs up to 2 ft. long: fls. in 2-3-fld. pendulous racemes; sepals and petals ascending, the fl. not opening wide, pale rosy mauve, acute, the former lanceolate, narrower than the oblong-ovate petals which are sometimes purple-striped; lip pale purple, striped with deep purple and with a maroon spot surrounded by a white zone. Ceylon. B.M. 4886. G.W. 14, p. 408.

50. *álbo-sanguíneum*, Lindl. Pseudobulbs up to 15 in. long, stout, cylindric, erect: racemes 2-7-fld.; fls. 2-3 in. across, buff-yellow, with 2 purple spots on lip; sepals oblong-lanceolate, acute, about half as broad as the oblong-oval petals which sometimes have a few red streaks at the base; lip broadly clawed, the blade broadly obovate or nearly orbicular, undulate. Moulmein and Tenasserim. B.M. 5130. F.S. 7:721. J.F. 2:203.

51. *lutèolum*, Batem. Pseudobulbs up to  $1\frac{1}{2}$  ft. tall, furrowed, cylindric: fls. 2-4, in lateral racemes, 2-2 $\frac{1}{2}$  in. across, primrose-yellow; sepals oblong-elliptic, narrower than the oval petals; lip with a few reddish streaks, slightly 3-lobed, the middle lobe oblong, emarginate, a tuft of yellow hairs below the tomentose disk. Moulmein. B.M. 5441. F.S. 23:2395 (as *D. Lowii*). J.H. III. 32:143; 51:519; 54:137. V.O. 57. Var. *chlorocéntrum*, Reichb. Fls. a little larger with greenish hairs on the lip. G.C. II. 19:340.

52. *ramòsum*, Lindl. (*D. Rückeri*, Lindl.). Pseudobulbs up to  $1\frac{1}{2}$  ft. tall, slender: fls. solitary or in pairs, about  $1\frac{1}{2}$  in. across; sepals and petals pale primrose-yellow, the dorsal sepal oblong, the lateral triangular, the petals narrower than dorsal sepal; lip 3-lobed, the lateral lobes white, rose-streaked, the middle lobe nearly orbicular, reflexed, deeper yellow than petals, much undulate. Trop. Himalayas. B.R. 29:60.

53. *ochreàtum*, Lindl. (*D. cambridgeanum*, Paxt.). Pseudobulbs up to 10 in. long, stout, curved, cylindric, decumbent: fls. in pairs, 2-3 in. across, rich golden yellow, except the maroon blotch on lip; sepals and petals oblong, acute, similar; lip with the concave blade orbicular, recurved on the margin, the upper surface downy. Trop. Himalayas. B.M. 4450. C.O. 16. Var. *luteum*, Hort. Fls. lemon-yellow, with blotch on lip of much lighter purple than in type.

54. *chrysánthum*, Wall. (*D. Paxtonii*, Lindl.). Pseudobulbs up to 6 ft. long, slender, furrowed, pendulous: fls. about 2 in. across, in racemes of 4-6, golden, except the 2 maroon spots on the lip; sepals oblong-oval; petals broadly obovate; lip denticulate, the middle lobe orbicular. Tropical Himalayas to Burma and southern China. B.R. 1299. Lind. 5:194. C.O. 2. G.C. III. 15:565; 40:374. Var. *anoph-tálmum*, Reichb. f. Lip. not spotted. Var. *microph-tálmum*, Reichb. f. Petals serrate, and the spots on the lip smaller.

55. *Hookerianum*, Lindl. (*D. chrysòtis*, Reichb. f.). Pseudobulbs up to 8 ft. long, pendulous: fls. 3-4 in. across, in pendulous racemes of 10-15, golden, except the 2 maroon spots on the lip; sepals and petals oblong,

acute, similar; lip with the blade broadly oval, velvety on upper surface, fimbriate, the divisions long and bearded. Trop. Himalayas and Bengal. B.M. 6013. Lind. 16:730. I.H. 20:155. J.H. III. 33:221. Var. *brachy-stachyum*, Kränzl. Fls. a little larger, fewer, in shorter racemes. Khasia Hills.

#### SECTION VI.

A. Fls. usually single.

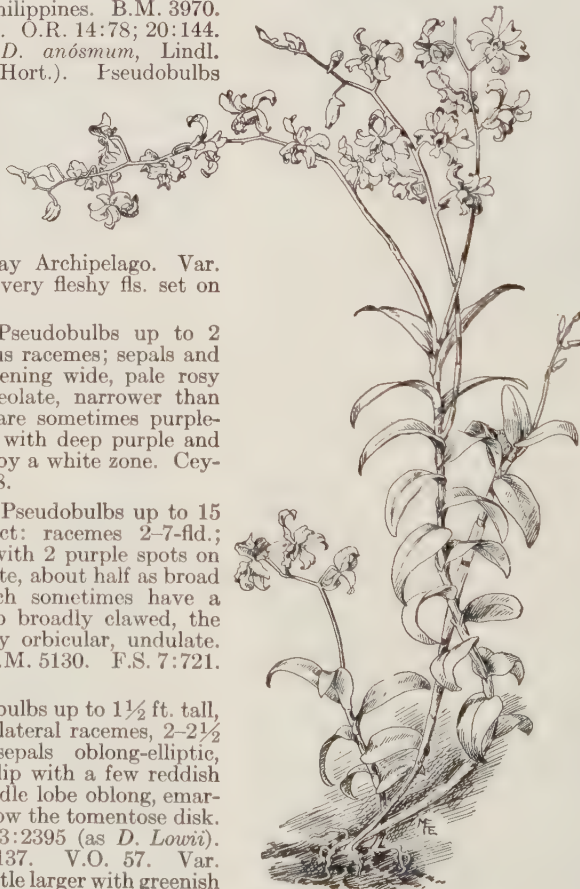

56. *Jenkinsii*

AA. Fls. in racemes.

57. *aggregatum*

56. *Jenkinsii*, Wall. Dwarf: pseudobulbs up to  $1\frac{1}{2}$  in. long, crowded, oblong, compressed, 1-lvd.: lvs. oblong, oval, 1-2 in. long: fls. solitary, about  $1\frac{1}{2}$  in. across, orange-yellow, with the disk on the lip darker; sepals oval, much narrower than the rhomboid petals, the lip downy above. Assam and Burma. B.R. 25:37.

57. *aggregatum*, Roxbg. Pseudobulbs ovate-fusiform, up to 2 in. long, crowded, 1-lvd.: lvs. 2-3 in.

1237. *Dendrobium superbiens*. ( $\times\frac{1}{7}$ )

long, oblong-oval: racemes pendulous, 6-12-fld.; fls. becoming orange-yellow with age, the disk deeper; sepals ovate, about half as broad as the nearly orbicular petals; lip with a pubescent disk. Burma and China. B.R. 1695. B.M. 3643. G.C. III. 50:82. C.O. 33.

## SECTION VII.

58. *bicameratum*, Lindl. (*D. breviflorum*, Lindl. *D. callibotrys*, Ridley). Pseudobulbs tufted, fusiform, up to 16 in. long: racemes short, fasciated, on the old pseudobulbs; fls. yellow, the sepals and petals marked with red spots in lines; lip cuneate, 3-lobed, the lateral lobes small acute, the middle lobe retuse, the callus fleshy, papillate. Trop. Himalayas.

## SECTION VIII.

59. *macrophyllum*, A. Rich. (*D. Veitchianum*, Lindl. *D. macrophyllum Veitchianum*, Hook. f. *D. ferox*, Hassk.). Pseudobulbs stout, clavate, up to 2 ft. long, furrowed, narrowed below: lvs. up to 1 ft. long: racemes many-fld., erect; fls. about 2 in. across; sepals oblong-ovate, hairy externally, pale yellowish green, larger than the whitish spatulate petals; lip 3-lobed, the lateral lobes round, purple-streaked, the middle lobe broader than long, with radiating purple lines. New Guinea, Java, Trinos, Philippines. B.M. 5649. H.F. 2:132. Var. *stenopterum*, Reichb. f. Fls. smaller, the mentum much reduced, the sepals and petals ochre, copiously dotted inside, marked outside with large brown spots.

## SECTION IX.

60. *Kingianum*, Lindl. Dwarf: pseudobulbs 2-3 in. long, attenuated upwards from a bulbous base, 2-5-lvd.: racemes few-fld.; fls. nearly 1 in. across; sepals and petals purple, the acute ovate sepals broader than the petals; lip white, marked with purple, 3-lobed, the lateral lobes obtuse, the middle lobe reniform, apiculate; spur yellow-tipped. Queensland. B.R. 31:61. B.M. 4527. J.F. 2:143. C.O. 38.

## SECTION X.

- A. *Sepals and petals undulate; ovary same color as fls.* ..... 61. *superbiens*  
 AA. *Sepals and petals not undulate; ovary green*  
 B. *Fls. about 2 in. across; middle lobe of lip retuse; disk papillose.* ..... 62. *bigibbum*  
 BB. *Fls. 2½-4 in. across; middle lobe of lip acute; disk smooth.* ..... 63. *Phalænopsis*

61. *superbiens*, Reichb. f. (*D. Goldiei*, Reichb. f. *D. Fitzgéraldii*, F. Muell.). Fig. 1237. Pseudobulbs up to 2½ ft., cylindric, somewhat narrowed at both ends, leafy above: peduncle nearly terminal, bearing a nodding terminal raceme; fls. about 2 in. across, crimson-purple, the sepals and petals often white-bordered; sepals oblong, reflexed, undulate, narrower than the obovate petals; lip 3-lobed, the lateral lobes round, the middle lobe oblong, wavy, reflexed. Austral. F.M. 1878:294. R. 1:39. G. 34:117. G.W. 14, p. 29. G.C. III. 49:36. C.O. 15.

62. *bigibbum*, Lindl. Pseudobulbs cylindric, somewhat fusiform, slender, up to 1½ ft. long, leafy: peduncle nearly terminal, slender, with a terminal many-fld. raceme; fls. 1½-2 in. across, purple-magenta, the lip darker; sepal oblong, acute, much narrower than the nearly orbicular petals; lip 3-lobed, the lateral lobes oblong, incurved, the intermediate one oblong, reflexed; crest white, papillose. Austral. B.M. 4898. F.S. 11:1143. Gt. 49:1473. Var. *candidum*, Reichb. f. Fls. white.

63. *Phalænopsis*, Fitzgerald. Fig. 1238. Pseudobulbs slender, up to 2 ft. long, leafy above: peduncle terminal or nearly so, slender, bearing a terminal raceme of 8-15 fls. which are 2½-3½ in. across; sepals lanceo-

late, acute, white, flushed pale rose, narrower than the rhomboid orbicular mauve petals with deeper veins; lip 3-lobed, the lateral lobes round, curved over the column, maroon-purple, the middle lobe pale purple, deeper veined. Austral. G.F. 5:440 (adapted in Fig.

1238). A.F. 16:1442. B.M. 6817. C.O. 4. Var. *hololeucum*, Hort. Fls. white. G.C. III. 28:239. Var. *Lindenæ*, Hort. Fls. large, creamy white. Var. *Rothschildianum*, Kränzl. Fls. 4 in. across, the sepals and petals white, suffused rose, the lip rose, intensely veined. Var. *rubescens*, Hort. An exceptionally dark form. Var. *Schröderianum*, Hort. Sepals white, the petals and lip deep violet. G.C. III. 28:238. Var. *splendens*, Hort. Fls. bright magenta-rose, white at base of segms. Var. *Statterianum*, Sander. Fls. deep violet. Var. *thundersleyense*, Hort. A dark-colored form.

1238. *Dendrobium Phalænopsis*. (×¼)

## SECTION XI.

- A. *Sepals and petals not yellow.*  
 B. *Pseudobulbs clavate, few-jointed.*  
 C. *Fls. single or in racemes of 2 or 3; sepals and petals contorted.* ..... 64. *tortile*  
 CC. *Fls. in 6- to many-fld. racemes; sepals and petals not contorted.*  
 D. *Lip white with a yellow spot; racemes loosely fld.* ..... 65. *Palpebræ*  
 DD. *Lip entirely yellow; racemes densely fld.* ..... 66. *thyrsiflorum*  
 BB. *Pseudobulbs cylindric, many-jointed.*  
 C. *Lip white, colored at base; sepals and petals white.*  
 D. *Middle lobe of lip broadly obcordate, resembling the petals.* ..... 67. *Fytchianum*  
 DD. *Middle lobe of lip narrowly oblong, much different from petals.* ..... 68. *leucolophotum*  
 CC. *Lip rose with a large orange blotch; sepals and petals rose.* ..... 69. *Bronckartii*  
 AA. *Sepals and petals yellow.*  
 B. *Color pale straw-color, tinted with rose.* ..... 70. *Farmeri*  
 BB. *Color clear yellow, not tinted.*  
 C. *Raceme of 2-4 fls.* ..... 71. *capillipes*  
 CC. *Raceme 10- to many-fld.*  
 D. *Lip deeply fimbriate, the divisions ciliate.* ..... 72. *chrysotoxum*  
 DD. *Lip minutely fimbriate.*  
 E. *Throat of lip marked with purple radiating lines.* ..... 73. *sulcatum*  
 EE. *Throat not lined.*  
 F. *Petals about as wide as sepals.* ..... 74. *densiflorum*  
 FF. *Petals nearly twice as wide as sepals.* ..... 75. *Griffithianum*

64. *tortile*, Lindl. Pseudobulbs up to 1 ft. long, clavate, furrowed: fls. in 2's or 3's, sometimes solitary; sepals and petals narrowly oblong, twisted, pale lilac;

lip convolute at base, nearly orbicular, primrose-yellow, with a purple basal spot. Malay Penins. B.M. 4477. O.R. 8:201. Var. *Dartoisianum*, O'Brien (*D. Dartoisianum*, De Wild). Sepals and petals yellowish. French India.

65. *Pálpebræ*, Lindl. Pseudobulbs up to 10 in. long, clavate, 4-angled: racemes loosely 5-10-fl.; fls. white, except the orange-yellow disk on lip; sepals oblong, narrower than the oval petals; lip oblong, downy above, fringed near the base. Burma, Siam, China.

66. *thysiflorum*, Reichb. f. (*D. densiflorum albo-luteum*, Hook.). Pseudobulbs up to 2 ft. long, terete, leafy: racemes pendulous, many-fl., lateral; fls. 1½-2 in. across; sepals and petals white, nearly transparent, the sepals oblong-ovate, acute, narrower than the nearly orbicular denticulate petals; lip orange-yellow, downy, the blade nearly orbicular, fimbriate. Moulmein and Burma. O.R. 6:209. C.O. 18. Gn. 60, p. 282. Gt. 55, p. 98. J.H. III. 48:313. I.H. 22:207. G. 19:204. F.M. n. s. 449. Var. *Walkerianum*, Warner. Pseudobulbs longer: fls. larger in longer racemes.

67. *Fytchi anum*, Batem. (*D. barbatulum*, Batem., not Lindl.). Pseudobulbs up to 1½ ft. tall, slender, erect: racemes 10-15-fl.; fls. 1½-2 in. across, white, except the rosy tint on sides of lip; sepals lanceolate, about one-third as wide as the obovate petals; lip 3-lobed, the lateral lobes incurved, the middle lobe broadly obcordate, with basal tufts of yellowish hair. Burma. B.M. 5444. Var. *roseum*, Berkeley. Fls. rose.

68. *leucolophotum*, Reichb. f. Pseudobulbs up to 1½ ft. tall, rather stout: raceme nodding, many-fl., 1-sided, on a long peduncle; fls. about 1 in. across, white, except the pale green on the side lobes and base of lip; sepals oblong-linear, keeled, much narrower than the obovate petals; lip 3-lobed, the lateral lobes incurved, the midlobe narrowly oblong. Malay Archipelago.

69. *Brónckartii*, De Wild. Pseudobulbs up to 3 ft. long, furrowed, terete, leafy: racemes pendulous, laxly many-fl.; fls. about 2 in. across, pale rose, except an orange blotch on lip; sepals elliptic-oblong; petals elliptic-ovate; lip nearly orbicular, denticulate, the disk velvety. Annam. B.M. 8252. R.B. 33:369.

70. *Färmeri*, Paxt. (*D. Pálpebræ*, Hook. not Lindl.). Pseudobulbs up to 1½ ft. tall, 4-angled, clavate, leafy: racemes pendulous, laxly many-fl.; fls. about 2 in. across; sepals and petals pale straw-color, tinted rose, the sepals oblong, acute, narrower than the broadly oval petals; lip nearly orbicular, deep yellow, downy above. Sikkim to Nepal and Burma. B.M. 4659. F.S. 7:741. J.F. 307. C.O. 30. Var. *albiflorum*, Hort. Sepals and petals white. Var. *aureo-flavum*, Hook. Sepals and petals golden.

71. *capillipes*, Reichb. f. Dwarf: pseudobulbs 2-3 in. long, fusiform: racemes few-fl.; fls. about 1¼ in. across, golden yellow, with a deeper blotch on lip; sepals lanceolate, acute, much narrower than the broadly oval petals; lip with the blade about orbicular, emarginate. Burma. B.M. 7639. Var. *élegans*, Reichb. f. Pseudobulbs taller, and base of lip deeper yellow.

72. *chrysotóxum*, Lindl. Pseudobulbs up to 1½ ft. tall, clavate or fusiform: racemes drooping, many-fl.; fls. about 2 in. across, golden yellow, except the red-dish streaked orange-yellow disk on lip; sepals oblong-elliptic, about half as broad as the obovate-oblong petals; lip orbicular, fimbriate, pubescent on upper surface. Burma. G. 18:465; 30:275. B.M. 5053. I.H. 5:164. C.O. 11. Var. *suavissimum*, Hook. f. (*D. suavissimum*, Hook. f.). Differs in its shorter, thicker pseudobulbs, and the large chestnut spot on the lip. Burma. Gn. 13:166. C.O. 11a.

73. *scalcatum*, Lindl. Pseudobulbs up to 10 in. long, clavate, furrowed: racemes 10-15-fl., short, nodding; fls. yellow, the lip deeper and purple-streaked; sepals

oval-oblong, narrower than the ovate petals, lip broadly ovate. Khasia Hills. B.R. 24:65. B.M. 6962.

74. *densiflorum*, Wall. Pseudobulbs up to 1½ ft. tall, 4-angled, clavate, leafy: racemes pendulous, many-fl.; fls. about 2 in. across; sepals and petals orange-yellow, nearly transparent, the acute sepals oblong-ovate, narrower than the denticulate nearly orbicular petals; lip nearly orbicular, orange-yellow, downy above. Nepal. B.R. 1828. B.M. 3418. F.S. 14:1397. G.W. 1, p. 223. J.H. III. 51:123; 64:94. C.O. 14. Var. *Schröderi*, Hort. (*D. densiflorum Schröderi*, Hort. *D. densiflorum album*, Hort.). Fls. larger in looser, longer racemes, the sepals and petals white, the lip deep orange, shading at margin to pale yellow. F.M. 502. A.G. 20:5.

75. *Griffithianum*, Lindl. Pseudobulbs up to 1½ ft. tall, furrowed, attenuated below: racemes pendulous, many-fl.; fls. about 2 in. across; sepals and petals bright yellow, the sepals oblong-oval, narrower than the nearly orbicular petals; lip orbicular, fringed, papillose above. Burma. Var. *Guibértii*, Veitch (*D. Guibértii*, Carr.). Fls. larger and more intensely colored: pseudobulbs more abruptly narrowed below.

## SECTION XII.

76. *crumenatum*, Swartz. Pseudobulbs fusiform, thickened above base, then attenuated: fls. appearing successively in upper part of st., white, or suffused with pale rose; sepals acute, the petals oblong-lanceolate, acute; lip cuneate, the lateral lobes rounded, the middle lobe nearly orbicular, the disk with 5 keels. Malay Archipelago. B.R. 25:22. B.M. 4013.

*D. acuminatum*, Rolfe=Sarcopodium acuminatum.—*D. am-  
plum*, Lindl.=Sarcopodium amplum.—*D. annamense*, Rolfe. Fls. buff-yellow, rather membranous. Annam.—*D. arcuatum*, J. J. Smith. Fls. white, with stout spurs curved forward at the tip. Java.—*D. Ashworthiae*, O'Brien. Fls. cream-white, except a few purple streaks at base of lip, the sepals lanceolate or triangular, the petals clawed. New Guinea. B.M. 8141. G.C. III. 29:86. C.O. 39.—*D. atroviolaceum*, Rolfe. Racemes many-fl., the fls. about 3 in. across, the sepals and petals primrose-yellow, claret-spotted, the lip 3-lobed, the disks violet, white-striped, the middle lobe recurved, dark violet streaked white at base, the upper part yellow, claret-spotted. New Guinea. B.M. 7371. C.O. 12. O.R. 3:305; 9:152; 16:69. G.W. 14, p. 407. J.H. III. 50:355.—*D. bellatulum*, Rolfe. Dwarf, tufted: fls. 1 or 2, axillary, white with a vermilion lip. China. B.M. 7985. G.C. III. 36:114.—*D. bicaudatum*, Reinw. Sepals and petals whitish, changing to greenish yellow, with faint purple lines; lip elongated; white. Java.—*C. Brändtii*, Kränzl. Resembles *D. Phalenopsis*. Fls. more fleshy, mauve-purple with silvery crests to the lip; sepals and petals twisted or curled.—*D. capituliflorum*, Rolfe. Fls. in dense axillary heads, greenish white, with column and disk of lip bright green. New Guinea.—*D. chidatum*, Parish. Sepals and petals yellowish green, the lip yellow, purple-lined. Moulmein. B.M. 5430. G.W. 11, p. 340. Var. *annamense*, Hort. A white-fl. form with fringed lip, purple at the base. Annam.—*D. Calogyne*, Reichb. f.=Sarcopodium Calogyne. C.O. 32.—*D. compactum*, Rolfe. A small-growing species: sepals and petals pure white, linear, acuminate; lip nearly as long as sepals, light green. China.—*D. convolutum*, Rolfe. Sepals and petals light green, with a few small dark brown markings at the base; lip green and dark brown. New Guinea.—*D. criniferum*, Lindl. "Fls. lasting only a single day, whitish, with a 3-lobed lip which breaks up in front into a fringe of long spreading yellow filaments." Malaya. G.C. III. 43:194.—*D. cucumerinum*, M'Leay. Dwarf: lvs. oblong, terete, with tubercles arranged in lines: fls. 3-5, white or yellowish, purple-streaked. New S. Wales. J.F. 4:358. B.M. 4619.—*D. delicatum*, Kränzl.—*D. subacaulis*.—*D. delicatum*, Bailey. Sepals and petals milky white the lip white, violet-lined, the callus golden, minutely violet-dotted. New Guinea. G. 34:245.—*D. epidendropsis*, Kränzl. Resembling an epidendrum: fls. greenish or yellow outside, yellow inside, about 1½ in. long. Philippines.—*D. Paulhaberianum*, Schltr. Fls. violet-rose; lateral sepals forming a mentum scarcely ½ in. long. Hainan.—*D. fusiiforme*, Bailey.—*D. speciosum* fusiforme.—*D. glomeratum*, Rolfe. Fls. rose-purple, in few-fl. fascicles, the lip golden carmine. Molucca. Gn. 65, p. 123.—*D. Goldschmidtianum*, Kränzl. Over a foot high: racemes short, about 12-fl.; fls. deep rose-purple. Formosa.—*D. Hildebrandtii*, Rolfe. Racemes axillary, 3-4-fl.; sepals and petals white, the lip primrose-yellow, the tube pubescent externally. Burma. B.M. 7453. O.R. 3:49; 12:153; 16:26.—*D. Hodgkinsonii*, Rolfe. Raceme 5-7-fl., terminal; fls. pale green, the lip purple-nerved. New Guinea. B.M. 7724.—*D. Imthurnii*, Rolfe. Probably the most robust of all dendrobiums in cult.: racemes axillary, many-fl.; fls. of medium size, white, with lilac streaks on lateral lobes of lip. New Hebrides. B.M. 8452.—*D. inaequale*, Rolfe. Flowering pseudobulbs separate from leafy ones, clavate, the fls. second, arising alternately from the margin of the internodes; sepals and petals white, the lip tubular, pale yellow, purple-streaked inside.

New Guinea. B.M. 7745.—*D. Jeraonidum*, Wight= *D. nutans*.—*D. kardense*, Schlecht. Fls. solitary in axil of lf. at apex of the st., small, white. A curious species. New Guinea.—*D. Madonnæ*, Rolfe= *D. rhodostictum*.—*D. monophyllum*, F. Muell. In habit resembling a bulbophyllum: racemes with 9-15 greenish yellow fls. Austral.—*D. Mörtii*, F. Muell. Fls. solitary; sepals and petals light yellow; lip whitish, marked with lilac with 3 undulate green keels on disk. New S. Wales.—*D. muricatum munificum*, Finet.= *Inobulbon munificum*.—*D. nutans*, Lindl. Fls. short, in few-fld. racemes, golden; sheaths hispidulous. Malabar. B.M. 7741. C.O. 28 (as *D. Jerdonianum*).—*D. punicum*, Rolfe. Fls. in racemes, light rose-pink, with light yellow tips to the sepals and petals. New Guinea.—*D. quinarius*, Rolfe. "Fls. light yellow with several light brown nerves in front of lip." New Guinea.—*D. rhodostictum*, F. Muell. Fls. white, with a few purple spots on margins of lateral lobes of lip. New Guinea. B.M. 7900 (as *D. Madonnæ*). G.C. III. 43:162.—*D. rosellum*, Ridley. Fls. rose-colored. Borneo.—*D. roseo-nervatum*, Schlecht. Fls. pale rose, borne at the summits of the sts. Sumatra.—*D. Sanderæ*, Rolfe. Pseudobulbs up to 3 ft. long, leafy: racemes lateral, 3-4-fld.; fls. large, white, the lip with purple stripes on the disk and lateral lobes, the middle lobe obovate, truncate, crenulate. S. E. Asia. B.M. 8351. G.C. III. 45:374. G.M. 52:621. O.R. 17:209.—*D. Schinzii*, Rolfe. Fls. pale green, very fugacious. Sumatra.—*D. Schurzei*, Rolfe. Fls. very large, white. A new species of the *D. Nearii* group.—*D. senile*, Pav. & Reichb. f. Pseudobulbs fusiform, hairy, as are the lvs.: fls. in pairs or solitary, fleshy, rich yellow, with a few orange streaks on lip. Burma, Tenasserim. Moulmein. B.M. 5520. G.W. 9, p. 422.—*D. spathaceum*, Lindl. A small species with slender pseudobulbs: fls. white. Sikkim.—*D. speciosum fusiforme*, Bailey. Pseudobulbs fusiform: fls. pale sulfur or straw-color to nearly white, the lip white, marked with violet. Austral. G. 33:361. G.C. III. 41:337.—*D. spectabile*, Miq. Pseudobulbs up to 2 ft., clavate, grooved: fls. 3 in. across, white, streaked and spotted with dark purple, the sepals and petals undulate, recurved, the former triangular-lanceolate, the petals much narrower; lip undulate, narrowly panduriform, the narrow lanceolate tip recurved. New Guinea and Solomon Is. B.M. 7747. C.O. 22. A.G. 21:239. G.M. 43:53. Var. *Simmondsii*, Hort. Lip much longer than in the type, white, veined with dark purple.—*D. spirium*, J. J. Smith. Fls. solitary; sepals and petals white. A distinct and singular species. Java, Borneo.—*D. striatum*, Hort. "Sepals and petals narrow and nearly equal; labellum as long as petals, narrow, with sides folded back, whitish tinged with rose." Philippines.—*D. subacule*, Reinw. Fls. fragrant, white speckled with purple on lip; lip with very short apiculate middle lobe. Queensland.—*D. taurinum*, Lindl. Pseudobulbs cylindric: racemes many-fld.; fls. large, the sepals white, the petals and lip pale rose, intensely striated. Philippines. G.C. III. 31:90. B.R. 29:28.—*D. tonkinense*, De Wild. Lip entire, furnished with crests, the median one very prominent. Tonquin.—*D. Treacherianum*, Reichb. f. = *Sarcopodium Treacherianum*.—*D. triflorum*, Lindl. = *Sarcopodium cymbioides*.—*D. undulatum* var. *Broomfieldii*, Fitzgerald. Fls. pale greenish yellow. N. Austral.—*D. Victoriæ-reginæ*, Lohr. Racemes few-fld.; sepals and petals white at the base, violet-purple above, the lip golden at the base, violet-purple above, marked with black-purple lines of papillæ. Philippines. G.M. 51:610; 54:556. Gn. 75, p. 370. C.O. 21. O.R. 20:17.—*D. Williamsii*, Day & Reichb. f. Pseudobulbs up to 1 ft. tall, hairy, as well as the lvs.: fls. usually in pairs, 2½-3 in. across, ivory-white or yellowish, the throat of lip bright orange-red. N. E. India. B.M. 7974. G.C. III. 35:341.—*D. Wilsonii*, Rolfe. Racemes 2- or 3-fld.; fls. delicate pink or nearly white, with small yellow blotch on disk of lip. W. China.—*D. Wolterianum*, Schltr. Racemes many-fld.; fls. rose-colored. New Guinea.

The following are some of the hybrid forms: *D. Ainsworthii*, Moore (*D. aureum* × *D. nobile*). Fls. white, more or less suffused with rose, the lip with a feathered purple spot. C.O. 1. Gn. 51, p. 338. G.C. II. 16:624. J.H. III. 62:281.—*D. Apolló grandiflorum* = *D. rubens*.—*D. Artemis* = *D. aureum* × *D. Ainsworthii*. O.R. 14:72.—*D. Aspasia* = *D. aureum* × *D. Wardianum*. O.R. 1:137.—*D. burfordiense* = *D. aureum* × *D. Linawianum*. G. 29:35.—*D. Cassiope* = *D. moniliforme* × *D. nobile*. C.O. 2.—*D. chrysodiscus* = *D. Ainsworthii* × *D. Findlayanum*.—*D. Curtissii* = *D. aureum* × *D. Cassiope*. Gn. 69, p. 145. O.R. 14:73.—*D. Dalhousii-nobile* = *D. nobile* × *D. pulchellum*. G.C. III. 27:379.—*D. dominyanum* = *D. nobile* × *D. Linawianum*.—*D. dulce* = *D. aureum* × *D. Linawianum*.—*D. Edithæ* = *D. nobile nobilis* × *D. aureum*.—*D. endocharis* = *D. aureum* × *D. monileforme*. G. 32:293. G.Z. 36, p. 195.—*D. eudsmum* = *D. endocharis* × *D. nobile*.—*D. Leechianum* = *D. aureum* × *D. nobile*. R.H. 1904:280. C.O. 1a.—*D. melanodiscus gloriosa* = *D. Ainsworthii* × *D. Findlayanum*. G.C. III. 35:219.—*D. melanodiscus pallens* = *D. Ainsworthii* × *D. Findlayanum*. J.H. III. 50:25.—*D. Rablingianum* = *D. nobile* × *D. ramosum*. Gn. 59, p. 198, desc.—*D. Rolfæ* = *D. nobile* × *D. primulinum*.—*D. Rolfæ roseum* = *D. nobile* × *D. primulinum*. Gn. W. 18:541.—*D. rubens grandiflorum* = *D. Ainsworthii* × *D. Findlayanum*.—*D. splendens* = *D. Ainsworthii* × *D. aureum*. G.M. 43:179. G.M. 65, p. 140.—*D. Thwaitesæ* = *D. Ainsworthii* × *D. Wiganisæ*. G.M. 47:273.—*D. Venus* = *D. nobile* × *D. Falconeri*. G.M. 51:459. C.O. 3.—*D. Wiganisæ* = *D. nobile* × *D. signatum*.—*D. Wiganisæ xanthochilum* = *D. nobile* × *D. signatum*. Gn. W. 20:161.—*D. Wiganisæ* = *D. Hildebrandii* × *D. nobile*. G.M. 44:167.—*D. xanthoocentrum* = *D. Wardianum* × *D. Linawianum*.

GEORGE V. NASH.

**DENDROCÁLAMUS:** A few large bamboos of the East Indies and China; see *Bamboo*.

**DENDROCHILUM:** *Platycinis*.

**DENDROMÈCON** (Greek *dendron*, tree; *mecon*, poppy). *Papaveraceæ*. An outdoor shrub in California, with bright yellow flowers; sparingly grown elsewhere.

Smooth low branching plant with rigid alternate mostly entire lvs.: fls. golden yellow, 1-3 in. across, single on short pedicels; petals 4, large; sepals 2; stamens many, short; fr. a linear curved grooved caps. 2-4 in. long.—Long considered to comprise a single species, but lately redefined by Fedde into 20 species, but only one species-name appears to be in the trade. The division into species is largely on foliage characters. It is not unlikely that some of the cult. material represents one or more of these segregates.

**rigida**, Benth. Rigid, very leafy, 2-10 ft. high: sts. up to 2 in. thick; bark whitish; branches stiff, erect: lvs. lanceolate or ovate-lanceolate, coriaceous, reticulately veined, very acute and mucronate: fls. on pedicels, 1-4 in. long: seeds black, almost globular. Dry parts of Coast ranges and in the Sierras. B.M. 5134. F.S. 14:1411. Gn. 50:292. J.H. III. 29:92.—Spring-flowering. In England it is somewhat tender, requiring some protection in winter. Prop. from seeds,

that take very long to germinate. Considerable variation in size of fls. appears to depend on the conditions in which plants are growing. Evergreen, but in hard winters in Calif., loses most of its lvs. by Feb., when, becoming scraggly, it may be cut back to ground for renewal. L. H. B.†

1239. Tip of leaf of *Dennstædtia punctilobula*. (× ¼)

1240. Fruiting lobe of *Dennstædtia punctilobula*.

**DENDRÓPANAX** (Greek, *tree Panax*). *Araliaceæ*. Unarmed trees and shrubs from Trop. Amer. and Asia, also China and Japan. Fls. hermaphrodite, rarely polygamous. Species about 20. *D. japonicum*, Seem. (*Hedera japonica*, Jungh.), may be secured from dealers in Japanese plants. The lvs. have been compared to *Fatsia japonica*, but are smaller and mostly 3-lobed but simple. The floral parts are in 5's: infl. umbellate, terminal nearly simple and not showy; berry globose. Cult in temperate house. N. TAYLOR.†

**DENDROPHYLAX:** *Polymrhiæ*.

**DENNSTÆDTIA** (August Wilhelm Dennstedt, early German botanist). *Polypodiaceæ*. Hardy or greenhouse ferns of wide distribution, often referred to *Dicksonia* but belonging to a different family from the tree ferns of the latter genus from the antarctic or southern hemisphere. Indusium inferior cup-shaped, open at top and adherent on outer side to a reflexed toothlet: lvs. 2-3-pinnatifid, from erect or creeping rootstocks. Species about 30; of simple cultural requirements.

**punctilobula**, Moore (*Dicksonia pilosiuscula*, Willd.). Figs. 1239, 1240. Rootstock slender, creeping, underground: lvs. light green, 1-2½ ft. long, 5-9 in. wide, usually tri-pinnatifid, under surface minutely

glandular, giving the dried lvs. a somewhat pleasant fragrance; sori minute, on small, recurved teeth. Canada to Tenn.—Sometimes called hay-scented fern, and boulder fern. Likes light porous soil and semi-shaded places. Variable.

**Smithii**, Moore. Lvs. thick, the under surface almost woolly, glandular, tripinnate; lower pinnae 9–12 in. long, 3–4 in. wide; sori 2–8 to each segm. Philippines.

**dissécta**, Moore. From the W. Indies, often 6–7 ft. high, with broad (2–4 ft.) lvs.—Sometimes seen in cult. and is well worth a place in the trade.

L. M. UNDERWOOD.

**DENTÀRIA** (Latin, *dens*, tooth; referring to the toothed rootstocks). *Cruciferae*. TOOTHWORT. Small early-flowering herbs, sometimes offered by dealers in native plants.

Hardy herbaceous perennials, usually with pleasant-tasting rootstocks, 2 or 3 lvs., mostly with 3 parts, and corymbs or racemes of large white or purplish fls. in spring; sts. mostly unbranched and not leafy below: lvs. palmately 3-divided or lacinate: petals surpassing the sepals; stamens 6; style slender: fr. a very narrow flat silique dehiscent from the base.—Probably 20 species in Eu., Asia and in N. Amer. The European and E. American species are readily told from Cardamine by habit and many obvious differences, but the W. American representatives of the 2 genera converge so that some botanists have merged Dentaria into Cardamine. (See E. L. Greene, *Pittonia*, 3:117–124.)

Several species are cultivated in Old World rockeries. They are of easy culture in light rich soil, and moist shady positions. Usually propagated by division, as seeds are not abundant.

A. Rootstock continuous, not tuberous.

**diphylla**, Michx. PEPPER-ROOT. Fig. 1241. Eight to 16 in.: rootstock several inches long, often branched, strongly toothed at the many nodes: st.-lvs. 2, similar to the root-lvs., close together; segms. 3, ovate or oblong-ovate, coarsely crenate, the teeth abruptly acute: petals white inside, pale purple or pinkish outside. Nova Scotia to S. C., west to Minn. and Ky. B.M. 1465.—Rootstocks 5–10 in. long, crisp, tasting like water-cress. Pretty spring fl.

AA. Rootstock tuberous or jointed.

B. Lvs. deeply 3-parted, but not into distinct lfts.

**laciniata**, Muhl. Eight to 16 in.: the st. pubescent above: tubers deep: st.-lvs. 3, with lateral segms. often 2-lobed, all oblong to linear, more or less sharply toothed: petals purplish to white. Que. to Minn., south to Fla. and La. Var. **integra**, Fern., has the lateral segms. entire or nearly so. *D. anómala*, Eames, is perhaps a hybrid with *D. diphylla*; Conn.

**macrocarpa**, Nutt. (*C. gemmata*, Greene). St. simple, 4–15 in.: lvs. 1–3, palmately or pinnately 3–5-parted, or divided; segms. linear to oblong, entire: fls. purple or rose: tubers with joints about 1 in. long. N. Calif. to Brit. Col.

BB. Lvs. of st. cut into 3 distinct lfts. (except sometimes in *D. californica*).

**tenélla**, Pursh. Six to 12 in.: tubers small, irregular: basal lvs. simple and round-cordate, crenate or sinuate; st.-lvs. 1 or 2, nearly sessile, sometimes bulbiferous; lfts. linear-oblong or linear, obtuse, entire: petals rose. Ore., Wash.

**californica**, Nutt. Tubers mostly small: st.  $\frac{1}{2}$ –2 ft. high: lvs. very variable; st.-lvs. 2–4, mostly short-petiolate, and above the middle of the st. with 3–5 lfts., rarely simple or lobed; lfts. mostly short-petiolulate, ovate to lanceolate or linear, entire or toothed: petals white or rose. Mountains and streams of Calif. and Ore.

**máxima**, Nutt. Ten to 16 in.: tubers near the surface, jointed, strongly tubercled: st.-lvs. 2 or 3, usually alternate; lfts. ovate or oblong-ovate, coarsely toothed and somewhat cleft or lobed, with petiolules: fls. white or purple-tinged. Maine to Mich. and Pa.

L. H. B.†

DEODAR: *Cedrus Deodara*.

**DEPÀRIA** (Greek, *depas*, a beaker or chalice; referring to the form of the involucre). *Polypodiaceae*. A small genus of Hawaiian and South American ferns related to *Dennstædtia*, rarely seen in cultivation in America. The sori are marginal and usually on stalked projections from the margin of the leaf.

**DÉRRIS** (Greek, *a leather covering*). Syn. *Dequèlia*. *Leguminosae*. Tropical, tall woody climbers (sometimes trees), one of which has been offered in S. Calif., but is now apparently out of cult. there. Lvs. alternate; lfts. opposite, the odd one distant; stipules none: fls. violet, purple or white, never yellow, in racemes or panicles or fascicles, papilionaceous, standard broad and rounded; wings oblique: pod indehiscent; 1- to several-seeded.—About 40 species, of little horticultural significance.

**scándens**, Benth. Climbing: lfts. 9–18, 1–2 in. long, oblong, obtuse, or acute, glabrous or minutely pilose beneath: fls. pale rose, in very long racemes: pod long, lanceolate, acute at both ends, narrowly winged at the base; ovules 6–8. S. Asia

and Indian Archipelago to Austral.—It has been offered in this country, but has not been successfully cult.

*D. alboribra*, Hemsl., from China, has been flowered at Kew in the palm house "where it covered some square yards of the roof:" fls. white, fragrant, with red calyx, in long panicles: lfts. coriaceous, glabrous, ovate-oblong: a climbing evergreen shrub: once confused with *D. Fordii*, Oliver. B.M. 8008.

L. H. B.

**DESCHAMPSIA** (for Deslongchamps, a French botanist, 1774–1849). *Gramineae*. Tufted perennials with shining spikelets in narrow or loose panicles, sometimes grown for dry bouquets.

Spikelets mostly 2-flid., with a hairy prolongation of the rachilla; glumes about as long as the florets; lemmas toothed, bearing a dorsal awn.—Species about 20, in the cooler regions of the northern hemisphere.

**cæspitosa**, Beauv. (*Aira cæspitosa*, Linn.). TUFTED HAIR-GRASS. HASSOCK-GRASS. Growing in tufts 1–3 ft.: blades firm, narrow; panicle open, the branches slender. G.M. 54:916. Common in N. U.S., extending

1241. *Dentaria diphylla*. ( $\times \frac{1}{2}$ )

south in the mountains.—In England, it is sometimes used by the farmers to make door-mats.

*flexuosa*, Trin. (*Aira flexuosa*, Linn.). WOOD HAIR-GRASS. Culms slender, 1-2 ft.: blades numerous, capillary; panicle open, the flexuous branches spikelet-bearing near the ends. Dept. Agric., Div. Agrost. 7:173. Open woods N. E. U. S.—Of some value for woodland pastures, as it will grow well in the shade. Also used for ornament. A form with yellow-striped foliage is sold under the name *Aira foliis variegatis*.

A. S. HITCHCOCK.

**DESIGN, FLORAL.** An important feature of the work of a retail florist is the making of floral designs or "set pieces." Fig. 1242. This work is directly opposed to the informal arrangement of flowers which is so much admired at the present time. See *Bouquets*, Vol. I. By artistic arrangement, however, these designs are now made less formal than in the earlier history of the retailer's work. These designs lend themselves well to the working out of various inscriptions and legends in flowers; therefore, these are most frequently

As has been stated, the present-day tendency in the arrangement of flowers in designs is to get as far away as possible from a stiff, set formality. A design must, of necessity, be distinct in outline, but by a careful and free use of ferns and other florists' "green," the effect may be made somewhat informal and pleasing. Various forms of the "shower" wreath illustrate this, as well as a loose arrangement of flowers, and even foliage and flowering plants about the base of a standing emblem.

The most common forms of floral designs in use at the present time are flat and standing wreaths, pillows, casket-covers, crosses, anchors, and the emblems of various fraternal orders, such as the Masonic square and compass, and the Odd Fellows' three links.

The flowers, of which these designs are made, vary in different stores. The price which is to be paid for the design usually governs the species and varieties used. Orchids, lilies, lilies-of-the-valley, roses and *Farleyense* ferns compose the most expensive designs; while carnations, stevia, Roman white hyacinths and other more common flowers, with asparagus fern, comprise the cheaper designs. Usually the florist determines the price the customer wishes to pay and selects the flowers in accordance with this. Within recent years there has come to be a demand for unusual material in designs, and boxwood, galax, leucothoe and magnolia leaves, ericas and other woody plants have been much used.

In making these designs, the arrangement must necessarily be quite formal; therefore, wire frames are used. These are made in large quantities by various

wire-working firms and are sold at wholesale at a comparatively low figure. In order to emphasize the particular formal outline and to hold the flowers permanently in place, the flower-stems are usually removed and the flowers then wired with 9- or 12-inch, No. 22 or No. 24 wire. The wire forms are first filled with sphagnum moss, which is moistened so that the flowers will retain their freshness, and the wired stems of the flowers are inserted in this moss. The wiring is an art, and the design-worker becomes so proficient in this that many flowers may be wired in a short period of time. This is necessary when many designs must be made quickly, as is so frequently the case in a flower-shop at the time of the funeral of a distinguished person.

Design work usually brings the retailer a substantial remuneration. In many instances, flowers of a lower quality may be used in designs than are demanded by persons buying cut-flowers. They must always be fresh, however; but, when roses are used, those having short stems are just as desirable as long-stemmed flowers. In carnations, many having a split calyx may be used when they would be salable in no other way.

If Roman hyacinths are used, the main truss may be sold as cut-flowers, and the secondary trusses used in designs.

The green elements in the design, which are used to emphasize the beauty of the flowers, vary much in different stores. Each designer has his own ideas regarding the uses of this material, but often he is compelled to use what is available at the precise moment when it is needed. Because of its excellent keeping qualities, the "dagger," or Christmas fern, is frequently used; but, when this is plainly visible in the finished design, it has a coarse appearance which cheapens the effectiveness of the piece. It may, however, be used as a cover for the frame and moss, with excellent effects. The "fancy dagger," or spinulose wood fern, is more

1242. A floral design.

attractive than the common dagger fern. One of the earlier greens used was smilax, but this has inferior keeping qualities to other kinds and is not so popular at the present time. It does not lend itself readily to a loose, formal arrangement. Both *Asparagus plumosus* and *A. Sprengeri* make excellent backgrounds for all design work. For softening effects to be worked among the flowers, nothing adds value to the design so much as a few sprays of *Adiantum Croweanum* or *A. Farleyense*. Often the foliage of the plants from which the flowers come adds a more pleasing effect than does the green of any other species. This is especially true when roses or lilies-of-the-valley are used.

Of the many designs made by the retailer of flowers, wreaths are probably the most in demand. They exhibit good taste, and many have excellent keeping qualities. One of the earlier forms was made of English ivy, and the effect was pleasing. This was especially so when the wreath was enriched with a large bunch of violets, arranged in a loose, artistic manner. Because of the difficulty of getting a sufficient quantity of these leaves, the ivy wreath has been largely replaced by that made of galax leaves. These have excellent

keeping qualities and are obtained in large quantities by wholesale dealers from the mountains of North and South Carolina. Both bronze and green galax may be secured, but the green is most satisfactory as it makes a more pleasing contrast with a larger number of colors of flowers. It is customary to make these in rather large sizes, a 16-inch frame, or even larger, being used. Usually the right-hand side of the wreath is decorated with roses, lilies-of-the-valley, or other flowers. A standing galax wreath, with a base of galax leaves, cocos palms, white roses and "valley," and the wreath itself decorated with white roses, lilies-of-the-valley, with shower sprays of "valley" and maidenhair ferns on dainty narrow ribbon, makes an effective design. If a single spray of cattleyas is placed among the roses and "valley," the effect is enriched wonderfully. Magnolia and leucothoë leaves are also used extensively for wreaths, but this foliage is heavier and less pleasing than galax. However, the buying public is tiring of the galax, and the retailer is searching the continents for something to replace it. Boxwood also makes a rich and attractive wreath. Wreaths made principally of flowers are often in demand, and when varieties are carefully selected, the results are pleasing. Fig. 1242 (redrawn from American Florist).

In selecting the flowers for any design, certain rules must be observed. In the first place, a designer must realize that, as in all other flower-arrangement, a lavish use of material is not essential to good effects. A flower has an individuality of its own, and this should be just as pronounced in a design as in a loose vase arrangement. At no time should the material be crowded. When an inscription is to be placed over the flowers, as, for example, in a pillow when carnations are to be the background, even then each carnation should show its form and the background should not be a mass of petals without definite shape. As a general thing, it is best to place the flowers in position first, after having covered the mossed frame with green, and then to work the foliage among the flowers where it is needed for the best effects. This method requires fewer flowers, and the effect is more artistic. In making a design, it must be remembered that there may be contrast of forms as well as colors. As a rule, there should not be over three contrasts of forms and two contrasts of colors, although there may be variations to this rule in special cases. As regards shapes and forms, it is quite essential that larger, heavier blooms, such as lilies and roses, should be contrasted with sprays of a light and graceful character, like lilies-of-the-valley and Roman hyacinths. The larger flowers are to be placed low in the arrangement, and the finer sprays higher. Often the center of a design is made of one particular species, as, for example, pink roses with their foliage; and the borders of the design are filled with sprays of lighter flowers, like lilies-of-the-valley with their foliage or that of the maidenhair fern. If in the arrangement of the larger flowers a few buds of the species used are added, the effectiveness of form is increased.

In selecting colors for designs, the lighter shades are the most desired, although in recent years there has come to be a freer use of darker colors. For example, a large wreath of Richmond or other red roses contrasted with lilies-of-the-valley or white Roman hyacinths, is very effective and is not considered out of place for a funeral design. The amateur should, however, avoid striking contrasts or to endeavor to harmonize unusual forms in flowers. The experienced designer may bring these together with pleasing effects, but this ability comes only after years of study and experience. Large designs are more easily arranged than small ones, and in them may be used a wider range of colors. The most striking colors are, however, widely separated, and between these the flowers should be of such tints that they assist in blending.

Flowers with a strong fragrance should not be used in designs if they can be avoided. They are especially objectionable if they are to be used in a dwelling-house where the rooms are often crowded. In a church or other large room, the fragrance is less noticeable. Polyanthus narcissi, tuberoses and freesias are especially objectionable. The more delicate odors of violets, lilies-of-the-valley and Roman hyacinths are less so.

The funeral designs most frequently ordered by the immediate family are pillows and casket-covers. Both of these demand careful treatment in making, the pillow being especially difficult. The smaller the pillow, the harder it is to produce a pleasing result. The flowers should be of a rich character, and it shows better judgment to select a less expensive wreath as a floral tribute than to purchase a pillow made of cheap flowers. Casket-covers should also be made of expensive flowers. These covers are not lasting, for they must of necessity be light in character; and moss, which is so necessary to retain moisture and freshness in the flowers, cannot well be used. Light wire of a fine mesh, such as mosquito netting, is cut of the desired size and the flowers which are usually of one species, like Easter lilies or roses, are wired to this with sufficient foliage or other green to cover the wire. A flower of some contrasting color may be used for a border; or a rich outline of smilax is effective.

The construction of many fraternal emblems in a pleasing, artistic way, demands all the fine points of the professional designer's skill. Often all rules of flower-arrangement have to be disregarded. Special emblems have to be made of special colors; and when an emblem must be made which calls for definite parts to be blue, others to be yellow, red, white and green, the problem to harmonize these is a serious one. The designer has no choice in such a case, and can meet this demand only with an attempt to reduce to the minimum these clashing contrasts in color.

As has been stated, formal designs in the arrangement of cut-flowers are a necessity, and for these there will probably always be a demand. The designer should have in mind, however, that it is possible to arrange flowers in a pleasing way and still emphasize the formal lines. Artists in this line of work are just as truly "born, not made," as in any other branch of art; and unless one has a genuine love for flowers and the artist's skill in their arrangement, the making of formal designs should not be attempted.

E. A. WHITE.

1243. *Desmanthus sicularis*. ( $\times \frac{1}{2}$ )

**DESMANTHUS** (name refers to flowers being in bundles). Syn. *Acuan*. *Leguminosæ*. About 10 herbs or shrubs in subtropical N. Amer., and 1 in the tropics of the Old World, a few of the American species reaching well north in the U. S.; probably not regularly cult., but now and then transferred to the garden for the effect of their bipinnate lvs. and small greenish white fls., in axillary peduncled heads or spikes. The genus is one of the Mimosa tribe, and the fls. are not papilionaceous: petals 5, distinct or very nearly so; calyx bell-shaped, 5-toothed; stamens 5 or 10, distinct, usually exserted: pod flat, narrow, straight or curved, several-seeded. *D. illinoensis*, MacM. (*Mimosa illinoensis*, Michx. *Acuan illinoensis*, Kuntze), occurs in prairies and river borders from Ind. west and south: 1-5 ft., nearly glabrous, perennial erect

herb: lfts. 20–30 pairs, obtusish. *D. leptolobus*, Torr. & Gray, occurs on prairies from Kans. to Texas: lfts. mostly fewer and acute, and peduncles much shorter (1 in. or less long).

**DESMAZÈRIA** (in honor of Desmazieres, a French botanist). *Gramineæ*. Plants resembling *Eragrostis*, sometimes grown as ornamental grasses.

Spikelets many-flid., strongly compressed, the lemmas keeled and coriaceous but faintly 3- or rarely 5-nerved, awnless: infl. several closely imbricated spikelets, arranged in a linear, dense, nearly simple spike-like panicle.—Species 4, 1 in Medit. region, and 3 in S. Afr.

**sicula**, Dum. (*Brizopyrum siculum*, Link). **SPIKE-GRASS**. Fig. 1243. Annual, 8–12 in.: spikelets  $\frac{1}{2}$  in., in a nearly simple spike. Eu.—Cult. for ornament and frequently used for edging. A. S. HITCHCOCK.

**DESMÔDIUM** (Greek, a *band* or *chain*; referring to the jointed pods). By some called *Meibomia*. *Leguminosæ*. **TICK TREFOIL**. Mostly herbs, upwards of 170 species, in temperate and warm regions of Amer., Asia, Afr. and Austral. Lvs. pinnate, with 3–5 (rarely 1) lfts.: fls. small and papilionaceous, in terminal or axillary racemes in summer, mostly purple; calyx with a short tube, more or less 2-lipped; standard broad; wings joined to the keel: pod flat, deeply lobed or jointed, the joints often breaking apart and adhering to clothing and to animals by means of small hooked hairs. Fig. 1244. A number of species are native to N. Amer., and are sometimes grown in the hardy border, where they thrive under ordinary conditions. One hothouse species, *D. gyrans*, is sometimes cult. for its odd moving lfts. *D. penduliflorum* and *D. japonicum* will be found under *Lepedeza*. Several of the native species are worthy of cult., but are practically unknown in the trade. The following have been offered by collectors: *D. canadense*, DC. (Fig. 1244); *D. cuspidatum*, Hook.; *D. Dillenii*, Darl.; *D. marilandicum*, Boott; *D. nudiflorum*, DC.; *D. paniculatum*, DC.; *D. pauciflorum*, DC.; *D. sessilifolium*, Torr. & Gray. The Florida beggarweed is *Desmodium tortuosum*, DC., of the W. Indies. It is coming into prominence in the S. as a forage plant (see *Cyclo. Amer. Agric.*, Vol. II, p. 214).

Two Chinese shrubby species have recently been intro. to Eu.: *D. amethystinum*, Dunn, growing 3–5 ft.: lvs. 3-foliate, the lfts. elliptic, 4–7 in. long: fls. amethystine,  $\frac{1}{2}$  in. long, in a terminal panicle. *D. cinerascens*, Franch., not Gray: broad bush, 3 ft. high, densely leafy: lvs. large, the lfts. lozenge-shaped: fls. rosy lilac to violet, in many racemes, produced in June and again in Sept.

The greenhouse species, *D. gyrans*, is of tolerably easy culture. It requires stove temperature, and, although a perennial, it is best treated as an annual. The best method of propagation is by seeds. These should be sown in February in a light, sandy soil, in 4-inch pots, and placed in a warm, close atmosphere, where they will soon germinate. The seedlings should be potted singly into small pots as soon as large enough to handle and grown on as rapidly as possible, using a mixture of good, fibrous loam and leaf soil in about equal proportions. By midsummer they will be good bushy plants, and, though not showy, they are very interesting. (Edward J. Canning.)

**gyrans**, DC. **TELEGRAPH PLANT**. Undershrub, 2–4 ft. high, with 3 oblong or elliptic lfts., the small lateral ones (which are almost linear) moving in various directions when the temperature is congenial, and especially in the sunshine: fls. purple or violet, in racemes and terminal racemose panicles. Ceylon to the Himalayas and the Philippines.—Grown occasionally as a curiosity, particularly in botanical collections. See Darwin's "Power of Movement in Plants," and various botanical treatises, for fuller accounts. L. H. B.

**DESMÓNCUS** (*band and hook*, referring to hook-like points on the lvs.). *Palmaceæ*. About 25 palms of U. S., S. Mex. to Bolivia and Brazil, differing from *Bactris* in the long slender climbing, caudex and technical characters. They are gregarious plants, with spines or hooks by means of which they climb or are elevated on growing trees, the sts. usually thin and flexuose and annular: lvs. scattered along the st., pinnate or pinnatisect, the parts or segms. opposite or alternate, the rachis produced into a long hook-bearing climbing organ: fls. greenish, in solitary spadices with 2 spathe-lvs.: fr. small, pea-shaped, red. *D. major*, Crueg., st. becoming very long and clinging to supports by the modified retrorse opposite segms. on the prolonged rachis: lvs. pinnate; lfts. 20 pairs, linear-acuminate and usually clustered; rachis spiny, dark-tomentose: spathe covered with brown prickles. Trinidad. Little known under glass, and reported as cult. in the open in S. Fla. and S. Calif. L. H. B.

1244. *Desmodium canadense* pods. (Nearly natural size.)

**DÉSMOS** (Greek, *chain*, on account of the fruit resembling nodes chained together). *Annonaceæ*. A genus established in 1790 by Loureiro and based upon *Desmos cochinchinensis* (Unona *Desmos*, Dunal, 1817; *Unona cochinchinensis*, DC., 1824). The flowers are composed of 3 sepals and 6 petals in 2 series, the latter valvate, nearly equal, and flat; stamens numerous, tetragonal-oblong or cuneate, the connective expanded above the dorsal oblong or linear-oblong pollen-sacs into a truncate hood-like process; receptacle, or torus, slightly raised, usually truncate or somewhat concave at the apex; carpels indefinite; ovules several, usually forming a single column, but sometimes sub-biseriate; style ovoid or oblong, recurved; ripe carpels indefinite, either elongate and chain-like from constrictions between the seeds, or baccate and spheroid. *D. cochinchinensis*, Lour., is a shrub with an erect or climbing st. and weak reclinate branches, lanceolate lvs., fragrant yellowish green pendulous fls., and reddish green moniliform frs. *D. chinensis*, Lour. (*Unona discolor*, Vahl), is a small tree of the E. Indies, with ovate-oblong lvs. glaucous beneath and extra-axillary sweet-scented aromatic fls., for the sake of which it is often cult. The greenish yellow corolla resembles that of *Canarium odoratum*, but the moniliform fr. consists of several joints, each containing a pea-like seed. It is used when green by the Chinese at Hongkong, who make from it a fine purple dye. *D. elegans*, Safford (*Unona elegans*, Thwaites), remarkable for its fr., which resembles strings of beads, and the very closely allied *D. zeylanicus*, Safford (*U. zeylanica*, Hook. f. & Thoms.), are endemic in the moist forests of Ceylon. Many species of *Desmos* have been erroneously referred to the genus *Unona*, based upon a S. American plant (*Unona discreta*, Linn. f.) not congeneric with the Asiatic genus above described, but more closely allied, if not to be identified with the genus *Xylopia*. See Safford, W. E., Bull. Torrey Bot. Club. 39:501–8 (1912). W. E. SAFFORD.

**DEUTZIA** (named by Thunberg in honor of his friend and patron, Johann van der Deutz). *Sarifragaceæ*. Very ornamental shrubs grown for their showy white or bluish flowers appearing in spring or early summer.

Upright; lvs. deciduous, rarely persistent, opposite, petioled, serrate, usually with rough stellate pubescence: fls. in panicles, rarely in racemes or in corymbs, white, sometimes purplish, epigynous; calyx-teeth 5; petals 5; stamens 10, rarely more, shorter than the petals; filaments usually winged and toothed at the apex; styles 3-5, distinct: caps. 3-5-celled, with numerous minute seeds.—About 50 species in E. Asia and Himalayas and 1 in Mex. Monograph by Schneider in M.D. 1904:172-188, and a hort. monograph by Lemoine in J.H.F. 1902:298-314; see also Rehder in Sargent, Plant. Wilson. 1:14-24 for Chinese species.

The deutzias belong to our most beautiful and most popular ornamental shrubs; they are very floriferous and of easy cultivation. *D. parviflora* and *D. grandiflora* are the hardiest, and also *D. gracilis*, *D. Sieboldiana* and *D. scabra* are hardy as far north as Massachusetts; the recently introduced *D. longifolia*, *D. Schneideriana*, *D. discolor*, and *D. Wilsonii* have proved fairly hardy with slight protection or in sheltered positions at the Arnold Arboretum. One of the most tender is *D. purpurascens*. Of the hybrids, *D. Lemoinei* is the hardiest, while *D. rosea* has proved about as hardy as *D. gracilis*; *D. kalmiaeflora*, *D. myriantha* and others are tender. Most of the deutzias have white flowers, but *D. rosea*, *D. purpurascens*, *D. longifolia*, *D. myriantha*, *D. kalmiaeflora* and some varieties of *D. scabra*, have the flowers carmine outside or pinkish. They flower most profusely if pruned as little as possible, although an occasional thinning out of the old wood soon after flowering will be of advantage.

The deutzias thrive in almost any well-drained soil, and are well adapted for borders of shrubberies. Potted plants forced with a temperature not exceeding 50° develop into beautiful specimens for the decoration of greenhouses and conservatories, especially *D. Lemoinei*, *D. gracilis* and *D. discolor*. The same plants cannot be forced again. Propagate readily by greenwood and hardwood cuttings, also by seeds sown in pans or boxes in spring.

## INDEX.

## A. Petals valvate in the bud.

## B. Fls. in panicles or racemes; calyx-teeth short (except in the hybrids).

## C. Lvs. glabrous below or nearly so.

1. *gracilis*, Sieb. & Zucc. Fig. 1245. Shrub, to 3 ft., with slender, often arching branches: lvs. oblong-lanceolate, acuminate, sharply serrate, with sparse stellate hairs above, nearly glabrous beneath, bright green, 1-2 in. long: fls. pure white, in racemes; petals erect or somewhat spreading, oblong; stamens much shorter than the petals; calyx-teeth persistent. May, June. Japan. S.Z. 8. P.F.G. 2, p. 7. F.S. 6:611. R.H. 1891, p. 203. G.M. 50:563. Gn. 39, p. 200. G.W. 12, p. 534. Gt. 1897:384. H.F. 1:48. J.F. 1:44. V. 7:217. Var. *aurea*, Schelle. Lvs. yellow. Var. *albo-marmorata*, Lemoine. Lvs. sprinkled with white.

2. *rosea*, Rehd. (*D. gracilis* × *D. purpurascens*. *D. gracilis rosea* and *D. discolor rosea*, Lemoine). Lvs. ovate-oblong, acuminate, bright green, slightly paler below, very sparingly stellate-pubescent on both sides: fls. pink, campanulate, in panicles; calyx-lobes longer than the tube; filaments slightly toothed or subulate, but strongly toothed in all varieties except in var. *venusta* and var. *multiflora*. F.E. 30:423. G. 27:274. Var. *campanulata*, Rehd. With large white campanulate fls. G. 28:485. Var. *venusta*, Rehd. With white fls. G. 27:275. Var. *multiflora*, Rehd.

With white fls. Var. *eximia*, Rehd. With white fls. tinted pink outside, in upright panicles. Var. *carminea*, Rehd. With light pink fls. tinted carmine outside. Var. *floribunda*, Rehd. With white fls. tinted pink outside. J.H.F. 1902:312. Var. *grandiflora*, Rehd. With fls. of the same color, but larger. All these varieties were originally described by Lemoine as varieties of *D. gracilis* except the two last ones, which he has under *D. discolor*.

CC. Lvs. stellate-pubescent beneath.

D. Filaments all toothed at the apex.

E. Calyx-lobes shorter than the tube; petals upright.

3. *scabra*, Thunb. Shrub, to 6 ft.: lvs. all petioled, ovate to ovate-lanceolate, rounded at the base, crenate-dentate, with rough pubescence on both sides, dull green, 1-3 in. long: panicles erect, 2-4 in. long; fls. white or blushed, with erect petals;

1245. *Deutzia gracilis*. (× 1/2)

calyx-lobes deciduous. June, July. Japan, China. S.Z. 6. B.M. 3838. B.R. 1718. S.B.F.G. II. 4:393. Gn. 37, p. 315. F.E. 31:1163. H.U. 1, p. 106. Var. *angustifolia*, Voss. Branches reddish brown; lvs. ovate-lanceolate, rougher. Var. *crenata*, Voss (*D. crenata*, Sieb. & Zucc. *D. dentata*, Hort. *D. mitis*, Hort.). Branches brown; lvs. ovate or oblong-ovate, less rough. This variety is less common in cult. than the former. Var. *marmorata*, Rehd. (var. *aureo-variegata*, Schneid.). Lvs. spotted with yellowish white. Var. *punctata*, Arb. Kew (var. *albo-punctata*, Schneid.). Lvs. sprinkled with white dots. Var. *Förtunei*, Schneid. Fls. larger. F.E. 31:1071. Var. *Wátereri*, Rehd. (var. *punicea*, Schneid. *D. crenata* *Wátereri*, Lemoine). Fls. white, tinted carmine outside. G.C. III. 39:340. Var. *plena*, Rehd. (*D. crenata* var. *plena*, Maxim.). Fls. double, white, tinged with rose outside. R.H. 1867: 70. F.S. 17:1790; 18:1850. G. 21:263. F. 1863:153. G.F. 8:112; here belongs also *Pride of Rochester*, with very large fls., faintly tinged with rose outside. Gn. 33, p. 514. Var. *candidissima*, Rehd. (*D. scabra* var. *albo-plena*, Schneid. *D. crenata* *candidissima* *plena*, Carr. *D. Wellsii*, Hort.). Fls. double, pure white.

4. *Schneideriana*, Rehd. Shrub, to 6 ft.: lvs. elliptic-ovate to elliptic-oblong, short-acuminate, sharply serrulate, stellate-tomentose and whitish below,  $1\frac{1}{2}$ -3 in. long; panicles broadly pyramidal; fls. nearly  $\frac{1}{2}$  in. long, white; stamens nearly as long as the petals; calyx-lobes deciduous. Cent. China. Var. *laxiflora*, Rehd. Lvs. oblong-lanceolate, acuminate, remotely denticulate, rough-pubescent above, thinly stellate-pubescent beneath and light green; panicles broad and rather loose,  $2\frac{1}{2}$ - $3\frac{1}{2}$  in. long; fls. about  $\frac{1}{2}$  in. long. June. W. China.—Only the var. is in cult.; similar to *D. scabra*, but the panicles looser and more graceful.

EE. Calyx-lobes longer than the tube.

5. *magnifica*, Rehd. (*D. scabra*  $\times$  *D. Vilmdrinæ*. *D. crenata* *magnifica*, Lemoine). Lvs. ovate-oblong, acuminate, appressed-serrulate, rough above, stellate-tomentose and grayish green below,  $1\frac{1}{2}$ - $2\frac{1}{2}$  in. long; fls. in erect panicles, white, double; sepals ovate or ovate-oblong, about as long as calyx, acute. June. G.M. 53:108. F.E. 31:322. Var. *latiflora*, Rehd., with very large single fls.  $1\frac{1}{2}$  in. across. Var. *superba*, Rehd., with large single campanulate fls. Var. *eburnea*, with white single campanulate fls. in loose panicles; stamens slightly shorter than petals. Var. *erecta*, Rehd., with white fls. in dense panicles. Var. *formosa*, Rehd., with double white fls. in large panicles. These varieties were originally described as vars. of *D. crenata*.

DD. Filaments, at least the longer ones, subulate, without teeth.

6. *Sieboldiana*, Maxim. (*D. scabra*, Sieb. & Zucc., not Thunb.). Low shrub, to 2 ft.: lvs. short-petioled, the pair below the panicle nearly sessile, ovate or ovate-elliptic to oblong-ovate, rounded or cordate at the base, rough and rugose above, stellate-pubescent and light green beneath, 1-2 in. long; panicles erect, loose, 2-3 in. long with appressed stellate pubescence mixed with spreading simple hairs; fls. white, rather small, with spreading petals; the shorter filaments usually abruptly contracted or with very short teeth; calyx-lobes persistent. June. Japan. S.Z. 7. G.C. III. 36:244. Var. *Dippeliana*, Schneid. (*D. scabra* *vèra*, Hort.). Lvs. broader and smaller; panicle only with appressed pubescence; stamens all subulate.—Graceful low shrub, but less showy than most other species.

BR. Fls. in corymbs or cymes.

C. Infl. many- or several-fl'd.

D. Calyx-teeth shorter than tube; anthers attached to the inside of the broad filament.

7. *setchuenensis*, Franch. (*D. corymbiflora* *erecta*, Hort.). Shrub, to 6 ft.: lvs. ovate-lanceolate to lanceo-

late, denticulate, rough-pubescent above, grayish green below and densely covered with stellate and simple hairs, 2-4 in. long; corymbs few-fl'd.; fls. less than  $\frac{1}{2}$  in. across; filaments with large broad teeth about as long as the nearly sessile anther. Cent. China. Var. *corymbiflora*, Rehd. (*D. corymbiflora*, Lemoine). Lvs. elliptic-ovate to ovate-lanceolate, acuminate, sometimes slightly cordate at the base, 2-4 in. long; corymbs many-fl'd.; fls. with spreading petals,  $\frac{1}{2}$  in. across;

1246. *Deutzia purpurascens*.

stamens about one-third as long as the petals, upright and connivent; styles shorter than stamens. June, July. Cent. China. B.M. 8255. G.C. III. 24:267. R.H. 1897, pp. 466, 467 (as *D. corymbosa*); 1898, p. 402. M.D.G. 1913:9 (lower picture). A.F. 14:166. Gng. 7:2.—The variety is much handsomer than the type; the fls. are comparatively small, but very numerous. Tender.

DD. Calyx-teeth lanceolate, as long or longer than the tube.

E. Anthers of the inner stamens borne on the inner side of the petaloid filaments; fls. pink or purplish outside.

8. *purpurascens*, Rehd. (*D. discolor* var. *purpurascens*, Franch.). Fig. 1246. Shrub, to 3 ft., with slender arching branches; lvs. ovate to ovate-lanceolate, crenately and unequally serrate, usually rounded at the base, green and only sparingly stellate-pubescent on both sides,  $1\frac{1}{2}$ - $2\frac{1}{2}$  in. long; corymbs 5-10-fl'd.; fls. with spreading petals, about  $\frac{3}{4}$  in. across, white, outside purple; the inner filaments with the anther below the apex. May, June. S. W. China. B.M. 7708. G.C. III. 2:45; 26:45. G.F. 7:287 (adapted in Fig. 1246). G. 27:201. R.H. 1895:64.—Very handsome, but tender.

9. *longifolia*, Franch. Shrub, to 6 ft., with upright branches; lvs. oblong-lanceolate to narrow-lanceolate, long-acuminate, narrowed at the base, thickish, rough and somewhat rugose above, grayish white and densely tomentose below,  $2\frac{1}{2}$ -4 in. long; corymbs many-fl'd., loose or dense; fls. with spreading petals, more than  $\frac{3}{4}$  in. across; the shorter filaments lanceolate with the anther inside near the middle. June. W. China. G.C. III. 51:409. Gn. 76, p. 243. G.M. 55:353. Var.

*Veitchii*, Rehd. (*D. Veitchii*, Veitch) with somewhat larger fls. in dense many-fl. corymbs. G.C. III. 51: suppl. 19. M.D.G. 1913:17.—One of the handsomest deutzias, but has proved hardy only under protection at the Arnold Arboretum.

EE. Anthers borne at the end of the filaments.

F. Fls. usually pinkish outside (hybrids of *D. purpureascens*).

10. *myriantha*, Lemoine (*D. Lemoinei* × *D. purpureascens*). Lvs. oblong-ovate, acuminate, rounded or broadly cuneate at the base, serrulate with spreading teeth, rough above, slightly stellate-pubescent beneath, 1½–3 in. long; fls. in broad corymbs, white, with spreading petals, partly imbricate in bud; filaments strongly toothed; anthers short-stalked; styles shorter than stamens; sepals triangular-ovate, about as long as calyx-tube. G.C. III. 52:45. F.S.R. 3, p. 193. A.F. 31:100, 101. M.D.G. 1907:376, fig. 5; 377, fig. 8. G.W. 13, p. 614. Var. *Boule Rose* and var. *Fleur de Pommier* have the fls. pink outside.

11. *kalmiæflora*, Lemoine (*D. parviflora* × *D. purpureascens*). Lvs. oblong to ovate-oblong, short-acuminate, broadly cuneate at the base, serrulate, rough above, slightly stellate pubescent below, 1–2½ in. long; fls. in rather small corymbs, pinkish, white in the center, light carmine outside, cup-shaped, ¾ in. across; petals mostly imbricate in bud; stamens half as long as petals; filaments with large teeth, nearly as long as the anthers; styles shorter than stamens. M.D.G. 1913:25. G. 27:199. Gn. W. 17:627.—One of the handsomest hybrids.

FF. Fls. white.

G. Filaments toothed below the apex.

12. *discolor*, Hemsl. Upright shrub, to 6 ft.: lvs. oblong-lanceolate, acuminate, cuneate at the base, denticulate, sparingly stellate-hairy above, stellate-tomentose and whitish below, 2–4 in. long; corymbs dense, hemispherical; pedicels usually not exceeding ¼ in.; fls. white, with spreading elliptic petals, about ¾ in. across; stamens about half as long as petals; filaments with large teeth usually as long as the stalk of the anther, the anthers of the inner stamens sometimes inserted inside a little below the apex. June. Cent. China. Var. *major*, Veitch. Fls. about 1 in. across. G. 30:307. R.B. 32, p. 174. M.D.G. 1913:9 (upper picture).

13. *Vilmorinæ*, Lemoine. Shrub, to 5 ft.: lvs. oblong-lanceolate, acuminate, narrowed at the base, serrulate, thinly stellate-pubescent above, densely so below and grayish white, 2–3 in. long; corymbs loose and large; pedicels ½–½ in. long; fls. more than ½ in. across; larger stamens only slightly shorter than petals; the teeth of the filaments shorter than the stalks of the anthers; styles as long as stamens. May, June. Cent. China. R.H. 1895, pp. 266, 267. F.V. 126. A very graceful shrub with its large and loose corymbs of white fls.

gg. Filaments, at least the longer ones, gradually narrowed toward the apex, without teeth.

14. *Wilsonii*, Duthie. Shrub, to 6 ft.: lvs. elliptic-lanceolate to oblong-lanceolate, short-acuminate, rounded or narrowed at the base, rough-pubescent above, grayish white and tomentose below, 2–4 in. long; corymbs compact, many-fl.; fls. white, more than ¾ in. across; stamens a third shorter than the petals; the shorter filaments usually abruptly contracted or sometimes with short obtuse teeth; calyx-lobes oblong-ovate, about as long as tube. May, June. Cent. China. B.M. 8083. G. 30:373. G.M. 51:473. M.D.G. 1912:27; 1913:16.

cc. Infl. 1–3-fl.; filaments with long and slender recurved teeth.

15. *grandiflora*, Bunge. Shrub, to 6 ft.: lvs. ovate, acuminate, rounded at the base, unequally and closely denticulate, rough pubescent above, whitish stellate-tomentose below and reticulate, 1–2½ in. long. fls. white, nodding, with slightly spreading petals about ¾ in. long; stamens about half as long as petals; calyx-lobes lanceolate, twice as long as tube. April, May. N. China.—A very distinct species, the earliest of all to bloom, the fls. appearing with the lvs.; has proved perfectly hardy at the Arnold Arboretum.

AA. Petals imbricate in the bud (or partly imbricate in the hybrid); fls. white.

16. *parviflora*, Bunge. Shrub, to 6 ft., with erect branches: lvs. ovate or oblong-ovate, usually narrowed at the base, finely serrate, with stellate hairs on both sides, often grayish green beneath, 2–3 in. long; fls. in many-fl. corymbs; petals roundish obovate, spreading, imbricate in the bud; longer filaments without teeth. June. N. China, Mongolia. G. F. 1:365. Gt. 11:370; 43, p. 65; 46, p. 382. R.H. 1892, p. 223. G.C. III. 14:153. Gn. 44, p. 181. F.S.R. 3, p. 197. A.F. 15:1297. Gng. 8:305, 307. Var. *Musæi*, Lemoine. Of stronger growth: lvs. larger and more acuminate; fls. creamy white in denser corymbs.

17. *Lemoinei*, Hort. (*D. gracilis* × *D. parviflora*. *D. angustifolia*, Dipp.).

Fig. 1247. Spreading shrub, to 3 ft.: lvs. elliptic-lanceolate, finely serrate with appressed teeth, with sparse stellate hairs above, nearly glabrous beneath, 1½–3 in. long; fls. in large corymbs or broad panicles, pure white; petals broadly ovate, spreading, partially valvate and partially imbricate in the bud; filaments with large teeth. G.F. 9:285 (adapted in Fig. 1247). A.F. 11:457; 15:1296. Gt. 44, p. 567; 46, p. 383. Gng. 4:135; 8:307. J.H. III. 34:77. G.C. III. 18:389. Gn. 48, p. 317. G.M. 39:251; 51:962, 963. G. 16:223. F.E. 24:747; 31:1119. G.W. 2, p. 173. M.D.G. 1895:438, 439.—A very desirable shrub, more vigorous and with showier fls. than *D. gracilis*. Excellent for forcing.

Var. *compacta*, Lemoine. Dwarfier and of more compact habit. *D. Boule de Neige*, Lemoine, with creamy white fls. (Gng. 8:306) and *D. Avalanche*, Lemoine, with pure white fls., are exceedingly floriferous forms.

*D. Brunoniæ*, R. Br.—*D. staminea* var. *Brunoniæ*.—*D. candellabrum*, Rehd. (*D. gracilis* × *D. Sieboldiana*. *D. gracilis* var. *candellabrum*, Lemoine). Shrub with slender branches and large white fls. in dense elongated panicles. R.B. 33, p. 372. R.H. 1908, p. 174. M.D.G. 1907:378. Var. *erecta*, Rehd. (*D. gracilis* erecta, Lemoine). Fls. smaller and panicles shorter. Var. *fastuosa*, Rehd. (*D. gracilis* fastuosa, Lemoine). Fls. in elongated rather dense panicles.—*D. candida*, Rehd. (*D. Lemoinei* × *D. Sieboldiana*. *D. discolor* candida, Lemoine). Upright shrub with large white fls. in panicles. M.D.G. 1907:376, fig. 6.—*D. carnea*, Rehd. (*D. Sieboldiana* × *D. rosea* grandiflora. *D. discolor* carnea, Lemoine). Upright shrub with pink rather small fls. in upright loose panicles.

1247. *Deutzia Lemoinei*.

Var. *lacteæ*, Rehd., with white fls., var. *stellata*, Rehd., with narrow spreading petals, pale pink or carmine-pink, and var. *densiflora*, Rehd., with white fls. in dense upright panicles, petals narrow; all these varieties described by Lemoine as varieties of *D. discolor*.—*D. compacta*, Craib. Allied to *D. parviflora*. Lvs. lanceolate, sparingly pubescent on both sides,  $\frac{3}{4}$ –2 in. long; fls. white in dense corymbs; filaments strongly dentate. W. China.—*D. corymbosa*, R. Br. Allied to *D. parviflora*. Lvs. rounded at the base, crenate-serrate, long-acuminate; fls. larger; all filaments toothed. Himalayas.—*D. discolor* vars.—*D. candida*, *D. carnea*, *D. elegantissima*, *D. excellens*.—*D. elegantissima*, Rehd. (*D. purpurascens*  $\times$  *D. Sieboldiana*). *D. discolor* var. *elegantissima*, Lemoine). Shrub, with slender branches, with numerous corymbs of large white, open fls. slightly tinted with rose inside and outside. R.B. 36, p. 387. M.D.G. 1907:377, fig. 9. Var. *arcuata*, Rehd. (*D. discolor* var. *arcuata*, Lemoine), with white fls. Var. *fasciculata*, Rehd. (*D. discolor* var. *fasciculata*, Lemoine). Flat white fls. tinted with pink.—*D. excellens*, Rehd. (*D. Vilmoriniana*  $\times$  *D. rosea grandiflora*). *D. discolor* var. *excellens*, Lemoine). Shrub, with slender upright branches, with large loose corymbs of pure white fls.—*D. globosa*, Duthie. Similar to *D. Wilsonii*, but smaller in every part: fls. creamy white in dense corymbs; filaments abruptly contracted below the apex. Cent. China.—*D. glomeruliflora*, Franch. Similar to *D. discolor*. Shrub, to 6 ft.: lvs. smaller, grayish white and soft-pubescent below; fls. white in dense and small, but very numerous corymbs along the slender branches; stamens like those of *D. longifolia*. W. China. Handsome and fairly hardy.—*D. gracilis* vars.—*D. candelabrum*.—*D. mollis*, Duthie. Allied to *D. parviflora*. Shrub, to 6 ft., with upright branches: lvs. elliptic-ovate to elliptic-lanceolate, soft-pubescent below, 2–4 in. long; fls. small, creamy white or slightly pinkish in dense flat corymbs; filaments subulate. Cent. China.—*D. reflexa*, Duthie. Allied to *D. discolor*. Lvs. oblong-lanceolate, 2–3 in. long; fls. smaller in loose corymbs, petals with reflexed margin; filaments with short teeth or abruptly contracted. Cent. China.—*D. staminea*, R. Br. Shrub, to 3 ft.: lvs. ovate or ovate-lanceolate, with whitish stellate pubescence beneath: corymbs many-fld.; fls. white, fragrant; filaments with large teeth. Himalayas. B.R. 33:13. Var. *Brunoniæ*, Hook. f. & Thoms. Lvs. less densely pubescent: fls. larger. B.R. 26:5 (as *D. corymbosa*).

ALFRED REHDER.

DEVIL-IN-A-BUSH: *Nigella*.

**DEWBERRY.** A blackberry-like fruit of trailing and climbing habit, now considerably grown in North America.

The botanist makes no distinction between dewberries and blackberries. But to the fruit-grower, trailing blackberries are dewberries, distinguished further, and probably better separated, by the flower- and fruit-clusters. In the true dewberries, the center flowers open first and flowers and fruits are few and scattered; in true blackberries—there are hybrids between the two in which the distinguishing characters are confused—the lower and outer flowers open first and flower- and fruit-clusters are comparatively dense. In the method of propagation there is a further distinction. In nature or under cultivation, dewberries are usually propagated from the tips, while blackberries are naturally propagated from suckers and under cultivation from root-cuttings.

The dewberry is an American fruit but very recently domesticated—if, indeed, it can be said to be domesticated, for it is the most uncertain and the most unmanageable of the small fruits. Its history as a garden plant, according to Card (Card's "Bush-Fruits," page 132) at the most does not go back further than 1863, and dewberries were not generally cultivated until well toward the close of the nineteenth century. Undoubtedly, despite unmanageable habits of growth, uncertainty in fruiting, the necessity of cross-pollination between varieties, capriciousness as to soils and lack of hardiness in northerly climates, the several species and the rapidly increasing number of varieties of dewberries, fill a place not occupied by the better-known and longer domesticated blackberries; for, as a rule, they ripen earlier and, when well grown, give larger, handsomer and better, or at least, differently flavored fruits than the blackberry. Moreover, from the several species of dewberries are being derived greatly improved varieties and hybrids between them and species of blackberries, of which there are now several under cultivation, as Wilson Early and Wilson Junior, which are most promising. These qualities make certain the place of the dewberry in home and commercial plantations and presage for it even greater value in the future.

Of the thirty or more species of *Rubus* which all could agree in calling blackberries and dewberries, the fruit-grower would probably distinguish five as dewberries. Between these there are hybrid forms under cultivation, as probably there are in the wild, and since

1248. Lucretia dewberry. ( $\times \frac{1}{4}$ )

there are also hybrids between blackberries and dewberries, the group is one of great taxonomic difficulty. The five species of dewberries are: (1) *Rubus procumbens*, Muhl., found in dry open places from Maine westward and southward. The species is characterized by woody, stoutly armed stems, membranaceous leaves, villous beneath, flowers few to several in leafy racemes, and short cylindrical fruits with few to many large drupelets. Var. *roribaccus*, Bailey, is a well-marked subspecies from West Virginia of more vigor, with larger flowers with elongated pedicels, and larger fruits; much cultivated with the Lucretia as the best representative. (Figs. 1248, 1249). (2) *Rubus invisus*, Bailey, is similar but stouter, with canes less procumbent, leaves more coarsely toothed, pedicels longer, and with the sepals large and leaf-like. The species grows wild from New York to Kansas and southwest and is the parent of several cultivated dewberries of which Bartel (Fig. 1250, adapted from G.F. 4:19) is the type. (3) *Rubus trivialis*, Michx., the southern dewberry, is quite distinct from 1 and 2. This species is found near the coast from Virginia to Florida and westward to Texas. It is characterized by slender trailing stems armed with recurved prickles, evergreen, smooth, leathery leaves, corymbs 1–3-flowered, and cylindrical fruits with many drupelets. Of the few varieties of this species cultivated, Manatee is probably the oldest and best known. (4) *Rubus rubrisetus*, Rydb., found in sandy soils in Missouri and Louisiana, is similar to *R. trivialis* but with stems, petioles, and pedicels rough with reddish, purplish hairs; the flowers are smaller but the corymbs are 3–9-flowered. The species is locally cultivated and gives some promise for greater improvement. (5) *Rubus vitifolius*, Cham. & Schlecht, is the Pacific Coast dewberry characterized by trailing, slender, pubescent canes with weak, straight or recurved prickles, leaves various, flowers staminate or pistillate on different plants.

1249. Lucretia dewberry. (Nat. size).

fruit of medium size, round-oblong, sweet. Several varieties, of which possibly Aughinbaugh and Skagit Chief are the best known, are cultivated in the far West. The loganberry is said to be a hybrid between this species and *R. Idæus*, and several less well-known hybrids are recorded.

The dewberry should receive under cultivation much the same treatment given the more common blackberry. The culture of the two differs chiefly in the dewberries requiring more care in training and must usually be better protected for the winter. The plants are trained on trellises of two or three wires or tied to stakes, the former method giving better results, but the latter being more common. The object in either case is threefold,—namely, to regulate the amount of bearing wood, to keep the vine out of the way of the cultivator and to keep the fruit off the ground. The plants should be set 4 by 7 feet apart, these distances varying somewhat in accordance with the variety and

1250. Bartel dewberry.  
( $\times \frac{1}{2}$ )

the soil. Pruning is a simple matter, consisting of shortening back young plants to 4 or 5 feet the first season to keep them from sprawling too much, cutting out old canes at any time after fruiting, and heading-in long shoots and laterals in early summer. From four to six fruiting canes are allowed to the plant. In northern climates, the vines must be laid on the ground and protected in winter with straw or other material. The plants thrive on a somewhat lighter soil than the blackberry—in fact some sorts require such a soil. Varieties should be intermixed to secure cross-pollination and thereby insure a good set of fruits and avoid the formation of nubbins.

Of about thirty named varieties, Lucretia, Bartel, Austin and Premo are the best. Of these four, Lucretia is far most commonly grown, being adapted to the greatest diversity of soils and is in general best suited to varying environments. For history and botany, see Bailey, "Evolution of our Native Fruits," for culture, see Card's "Bush-Fruits," and Cornell Bulletins Nos. 34 and 117. Consult *Blackberry*, *Loganberry* and *Rubus*.

U. P. HEDRICK

DEYEUZIA: *Calamagrostis*.

**DIACATTLEYA** (compounded of *Diacrium* and *Cattleya*). *Orchidaceæ*. A genus established to include hybrids between the two genera, *Diacrium* and *Cattleya*. A hybrid between *Diacrium bicornutum* and *Cattleya Mendelii* is known as *Diacattleya Sanderæ*. It was raised by Sander & Sons. The fls. are pure white, the lip with a pale yellow disk and small rose markings. G.C. III. 49:290. *D. Còlmanix*, Hort. (*Diacrocattleya Còlmanix* is a hybrid between *Diacrium bicornutum* and *Cattleya intermedia* var. *nivea*. G.C. III. 43:114. J.H. 56:167. It resembles a slender plant of *Diacrium*

*bicornutum*: sepals and petals pure white, lip slightly tinged primrose-yellow. GEORGE V. NASH.

**DIACRIUM** (*through and point*; the sts. are surrounded by sheaths). *Orchidaceæ*. Four Trop. Amer. epiphytes, closely allied to *Epidendrum*, with which they have been included. It differs from that genus in the fact that the column and lip are not united. Fls. showy, in loose racemes: lvs. few, sheathing; pseudobulbs slender. Cult. of *Epidendrum* and *Cattleya*.

**bicornutum**, Benth. (*Epidendrum bicornutum*, Hook.). Pseudobulbs 1–2 ft. long, hollow, bearing dry sheaths: lvs. short and leathery: raceme slender, 3–12-fld.; fls. white, with small crimson spots on the 3-lobed lip, fragrant. B.M. 3332. G.C. III. 16:337. J.H. III. 33:29. O.R. 12:113; 16:81; 20:361.—A handsome orchid, requiring high temperature.

*D. bidentatum*, Hemsl. (*Epidendrum bidentatum*, Lindl.), of Mex., has been listed in trade catalogues, but it is practically unknown to cult., and is probably not now in the American trade.

L. H. B.

**DIALÆLIA** (Compounded of the genera *Diacrium* and *Lælia*). *Orchidaceæ*. *D. Velchii*, Hort., is a hybrid between *Diacrium bicornutum* and *Lælia cinnabarina*. Pseudobulbs fleshy: fls. 9 or 10, the segms. white suffused with lilac, also showing a bronze tint derived from the *Lælia* parent.

DIAMOND FLOWER: *Ionopsidium*.

**DIANDROLÏRA** (*two-stamened Olyra*). *Gramineæ*. A single species raised at Kew some 8 years ago from seed supplied by Sander but native country unknown: differs from *Olyra* in its twin spikelets and other characters, the upper one being male and the lower one female, the male fls. with 2 stamens. The species is *D. bicolor*, Stapf, a perennial densely tufted grass with erect culms bearing 1–3 lanceolate or lance-oblong lvs. that are dark green above and violet-purple beneath.

**DIANÉLLA** (diminutive of Diana, goddess of the hunt). *Liliaceæ*. Tender perennial rhizomatous plants, related to *Phormium*.

Leaves hard, linear, sheathing, grass-like, crowded at base of st., often 2–3 ft. long: fls. blue, in large loose panicles, on delicate pendent pedicels; perianth withering but not falling, with 6 distinct spreading segms.; stamens 6, with thickened filaments; ovary 3-celled, each cell several-ovuled, the style filiform and stigma very small: plant bearing great numbers of pretty blue berries, which remain attractive for several weeks, and are the chief charm of the plant.—There are about a dozen species in Trop. Asia, Austral. and Polynesia. They perhaps succeed best in the open border of a cool greenhouse. Prop. by division, or by seeds sown in spring in mild heat. They are little known in this country. They are spring and summer bloomers.

A. Lvs. radical or nearly so.

**tasmánica**, Hook. f. Height 4–5 ft.: lvs. numerous, in a rosette, broadly ensiform, 2–4 ft. long,  $\frac{3}{4}$ –1 in. wide, margined with small reddish brown spines that cut the hand if the lvs. are carelessly grasped: panicle very lax, surpassing the lvs. 1–2 ft., with as many as 60 fls.; fls. pale blue, nodding,  $\frac{1}{2}$ – $\frac{3}{4}$  in. across, segms. finally reflexed; anthers 1 line long: berries bright blue, on very slender pedicels. Tasmania and Austral. B.M. 5551. Var. *variegata*, Bull. Lvs. handsomely striped with light yellow. R.B. 29:61.

**lævis**, R. Br. Lvs. 1–1½ ft. long, 6–9 lines wide, less leathery and paler than in *D. cærulea* and at first slightly glaucous: panicle deltoid, the branches more compound than in *D. revoluta*, outer segms. of the perianth with 5 distant veins, inner ones densely 3-veined in the middle third; anthers 1½ lines long. Eastern temperate parts of Austral. B.R. 751. L.B.C. 12:1136 (both as *D. strumdsa*).

*revoluta*, R. Br. Height 2-3 ft.: lvs. in a rosette, 1-1½ ft. long, 3-4 lines wide, dark green, purplish at the base and margin, not spiny at the margin: panicle branches short, ascending; fls. later than *D. cærulea*; veins of the perianth-segms. crowded into a central space. W. and E. Austral. in temperate parts. Tasmania. B.R. 734 (as *D. longifolia*); 1120.

AA. Lvs. more or less scattered on sts. that often branch at base.

*cærulea*, Sims. Sub-shrubby, with a short st. in age, branching: lvs. about 6, clustered at the ends of branches, 9-12 in. long, 6-9 lines wide, dark green, rough on the back and margin: outer perianth-segms. with 5 distant veins, inner ones with 3 closer veins. E. Temp. Austral. B.M. 505.

*nemorosa*, Lam. (*C. ensifolia*, Red.) Caulescent 3-6 ft. high, the lvs. never in a rosette, numerous, hard, linear, 1-2 ft. long, 9-12 lines wide, lighter-colored on the keel and margin: fls. blue or greenish white. Trop. Asia, China, Austral., Hawaiian Isls. B.M. 1404.

WILHELM MILLER.

L. H. B.†

**DIANTHÈRA** (*double anther* referring to the separated anther-cells). *Acanthaceæ*. WATER-WILLOW. Herbs, mostly of greenhouses and warmhouses, and sometimes of open planting in mild climates.

Glabrous or pilose perennial herbs or sometimes somewhat woody, mostly of wet places, with opposite, mostly entire lvs.: fls. mostly purplish or whitish, irregular, usually in axillary spikes, heads or fascicles, or the clusters combined in a terminal thyrse; corolla slender-tubed, 2-lipped, the upper lip erect and more or less concave or arched and entire or 2-toothed, the lower lip 3-lobed or 3-crenate and spreading, and with a palate-like structure; anther-cells separated on a broadened connective, not parallel with each other: fr. an oblong or ovoid 2-celled caps., the seeds 4 or less: floral bractlets small or minute.—Probably more than 100 species, mostly in warm and tropical countries. Lindau in Engler & Prantl unites it with *Justicia* as a subgenus, and the number of species is estimated as more than 70 in Trop. Amer. The diantheras are little known in cult. *D. Pohiana* is to be found in Jacobinia. The treatment given Jacobinia and *Justicia* applies to these plants.

*americana*, Linn. St. angled, 1-3 ft.: lvs. narrow-lanceolate, 3-4 in. long, nearly sessile: fls. several in a close cluster with a peduncle mostly exceeding the lvs., pale violet or whitish, the corolla mostly less than ½ in. long, the tube shorter than the lips. In water, Quebec to Wis., Ga. and Texas.—Sometimes transferred to garden bogs and streams.

*secunda*, Griseb. (*Justicia secunda*, Vahl). Nearly glabrous, constricted at the nodes: lvs. ovate or ovate-lanceolate, acuminate: fls. crimson, short-pedicellate, in a usually 1-sided panicle; lower lip 3-crenate. W. Indies. B.M. 2060.

*pectorâlis*, Gmel. (*Justicia pectorâlis*, Jacq.). GARDEN BALSAM. St. slender, often woody, 1-3 ft.: lvs. lanceolate-acuminate or nearly oblong, to 4 in. long: fls. rosy or pale blue, with a parti-colored throat, rather distant in elongated branched mostly 1-sided spikes. W. Indies, Mex., Brazil.

*bullata*, N. E. Br. St. terete, purplish: lvs. elliptic, to 4½ in. long, short-stalked, cordate at base, bullate or puckered between the veins, dark green above and purple-veined beneath: fls. whitish, small, clustered. Borneo. I.H. 33:589.—A. handsome foliage subject, with the appearance of a rubiaceus plant.—*D. ciliata*, Benth. & Hook. (*Jacobinia ciliata*, Seem.). St. obscurely 4-angled, 2 ft.: lvs. ovate-lanceolate, 2-3 in. long, short-stalked: fls. violet with white palate, sessile, many in a short-peduncled fascicle; calyx ciliate; corolla-tube ¾ in. long, cylindrical; upper lip very small, 2-lobed, concave and recurved; lower lip very large and showy (¼ in. across), flat, with 3 large lobes. Costa Rica. Panama(?). B.M. 5888 (as *Beloperone ciliata*, Hook. f.).—Described as an annual. Perhaps not of this genus.

L. H. B.

**DIANTHUS** (Greek for *Jove's flower*). *Caryophyllacæ*. PINK. Small herbs, many of them prized for their rich and showy flowers in the open garden; and one is the carnation. Some of them are deliciously fragrant.

Mostly perennials forming tufts and with grass-like lvs., and jointed sts. with terminal fls. and opposite lvs. From kindred genera *Dianthus* is distinguished by the sepal-like bracts at the base of a cylindrical calyx (Figs. 802, 803); petals without a crown; styles 2: caps. opening by 4 valves. Mostly temperate-region plants, of S. Eu. and N. Afr., but occurring elsewhere, one of them (a form of *D. alpinus*) being native in N. Amer.; about 250 species are recognized. The fls. are usually pink or red, but in garden forms white and purple are frequent colors. Most of the cult. species are hardy in the N. and are easy of cult. The perennial species are excellent border plants. The chief care required in their cult. is to see that the grass does not run them out. Best results in flowering are secured usually from 2-year-old seedling plants. The genus abounds in attractive species, and other names than those in this article may be expected to appear in the catalogues. Numbers of species are likely to be grown by rock-garden specialists. Pinks are among the old-fashioned flowers, particularly *D. plumarius*, which was formerly common in edgings and in circle-beds. The sweet williams are always popular. All the species described in this article are perennial, but there are a few annuals in the genus but apparently not in cult. Two weedy annual species, *D. prolifer*, Linn., and *D. Armeria*, Linn., are naturalized in the eastern states, and two or three others have run wild more or less. See E. T. Cook, "Carnations, Picotees, and the Wild and Garden Pinks," London, 1905. See p. 3568.

*Dianthus* like a warm soil, and one that will not become too wet at any time, especially in winter, when the perennial kinds are grown, as they are often killed not so much from cold as from too much ice around them. Snow is the best possible protection, but ice is the reverse.—All *dianthus* are readily propagated from seeds sown in rich soil (usually beginning to bloom the second year), but the double kinds are reproduced from cuttings alone to be sure to have them true, and in the fall months cuttings are easily rooted if taken with a "heel" or a part of the old stem adhering to the base of the shoot; so that to make cuttings it is best to strip them off rather than to make them with a knife. It will be found, also, that cuttings made from plants growing in the open ground do not root readily but seem to dry up in the cutting-bench; if the plants to be increased are carefully lifted and potted, placed in a temperature of say 50° until young growth shows signs of starting, every cutting taken off at this stage will root easily. The transition from outdoors to the propagating-house should not be too abrupt. Another method of propagation is by layering, and with the garden pinks, or forms of *D. plumarius*, it is the easiest and surest. After hot weather is past, stir the soil round the parent plant, take the branches that have a portion of bare stem, make an incision half way through and along the stem for an inch, and peg this down in the soil without breaking off the shoot (Fig. 809). Roots will be formed and good strong plants be the result before winter. The layering method is specially suitable to such species as *D. plumarius*, *D. Caryophyllus* and double forms of others, such as sweet william.—Among the species are various pretty little alpine tufted sorts as *D. neglectus*, *D. glacialis* and *D. alpinus*, all of which are of dwarf close habit, not exceeding 3 inches high and having very large single flowers of brightest colors. These are suited only for rock-gardening, as on level ground they often become smothered with weeds or swamped with soil after a heavy rainstorm, and to these two causes are attributable the failures to cultivate them. (E. O. Orpet.)

A. Fls. mostly in cymes or in heads, often densely aggregated, the cluster often subtended by involucre-like lvs.

B. Petals not bearing hairs or barbs: bracts dry.

1. *cinnabarinus*, Sprun. A foot high, woody at base, many-stemmed, the sts. simple and 4-angled, blooming in Aug. and Sept.: lvs. linear, sharp-pointed and rigid, 7-nerved: fls. few in heads; petals fiery red above, paler beneath, glandular; stamens included. Greece.— Handsome little species; useful for hardy border or rockery.

2. *Pancicii*, Velen. (*D. stenopetalus* var. *Pancicii*, Williams). Cespitose, glabrous, 2-3 ft., the sts. slender and 4-angled: lvs. linear-acuminate, soft, 3-nerved, in a dense grass-like basal tuft: fls. 5-15 in a paniculate cyme or head; calyx green; petals rose or crimson. Balkan region. Var. *grandiflorus*, Hort., has very stout sts., large clusters, and large purple-carmine fls.

BB. Petals with hairs or barbs on the lower part of the blade.

c. Plant glabrous but usually not glaucous.

3. *barbatus*, Linn. SWEET WILLIAM. Fig. 1251. Readily grown from seed and flowering well the second year: glabrous, the sts. 4-angled, 10-20 in. high, simple or branched only above: lvs. broad and flat or conduplicate, 5-nerved: fls. several to many in a round-topped dense cyme, the petals toothed and bearded, red, rose, purple or white and also varicolored in garden forms, the bracts subtending the calyx 4 and long-pointed. Russia to China and south to the Pyrenees. G. 1:372. Gn. M. 2:217; 14:55. F. E. 23:219.—The sweet william is one of

1251. Sweet William—*Dianthus barbatus*. ( $\times \frac{1}{2}$ )

the oldest garden fls. It is sure to be found in the old-fashioned gardens. The cult. forms run into many colors. Sometimes found along roadsides as an escape. There are double-fl. forms. R.H. 1894, p. 277. Some of the modern improved large-fl. forms are very showy, and produce their bloom over a long season. *D. Laucheanus*, Bolle, is a hybrid of *D. barbatus* and *D. deltoideus*. Gt. 53:1528.

4. *carthusianorum*, Linn. (*D. atrorubens*, Willd.). Hardy, glabrous, scarcely glaucous, 12-20 in. high, the st. angled: lvs. linear and pointed, without prominent nerves when fresh: fls. in a dense, 6-20-fl. head (sometimes the clusters very few-fl.), in shades of red, odorless, the petals sharply but not deeply toothed, the cluster subtended by very narrow or even awl-like lvs.; calyx-bracts 4, coriaceous, yellowish or straw-colored. Denmark to Portugal and Egypt. B.M. 1775, 2039.—Widely variable. Little planted in American gardens.

cc. Plant glabrous and glaucous.

5. *cruentus*, Griseb. (*D. atrococcineus*, Hort.). Cespitose, glaucous, glabrous: st. 1-2 ft., terete, forking: lvs. linear or lance-linear, sharp acuminate, spreading, 7-nerved, the cauline linear-appressed and 5-nerved: fls. deep blood-red, small, about 20 in a subglobose dense head, odorless; petals red-hairy towards the base. July. Greece and N.

6. *giganteus*, Urv. Cespitose, glabrous, glaucous, 2-3 ft. or more, simple: lvs. long-linear, 7-nerved, plane, spreading and acuminate: fls. 10-12 in a head, red, the petal-blade obovate-cuneate. Balkan region. Gn. 66, p. 122.

ccc. Plant woolly, glaucous.

7. *capitatus*, Balb. Plant glaucous, woolly, 12-16 in., simple, st. 4-angled: lvs. linear, acute, plane, spreading, 7-nerved, those on the st. 5-nerved: fls. 6-8 in a head, the petals purple-spotted. Siberia to Servia.

cccc. Plant viscid-pubescent.

8. *viscidus*, Bory & Chaub. Cespitose, pubescent and sticky, about 12 in., simple: lvs. linear, acuminate, soft, plane, 1-3-nerved: fls. 3-6 in a fascicle, the petals purple-spotted, the blade obovate-cuneate and few-toothed. Bulgaria, Greece, Turkey.—Runs into several marked forms.

AA. Fls. solitary, or loosely in 2's or 3's.

B. Calyx-bracts short and broad, mostly appressed.

C. Petals fimbriate.

D. Teeth of calyx mucronate.

9. *plumarius*, Linn. (*D. scoticus*, Hort.). COMMON GRASS OR GARDEN PINK. SCOTCH PINK. PHEASANT'S-EYE PINK. Low, tufty, 1 ft.: sts. simple or forked: plant blooming in spring and early summer, very fragrant: lvs. elongate-linear, keeled, spreading or recurved, thickish, 1-nerved, blue-glaucous: fls. medium size, rose-colored (varying in cult. to purple, white and variegated), the blade of the petal fringed a fourth or fifth of its depth; calyx cylindrical, with short broad-topped mucronate bracts. Austria to Siberia. Gn. 66, p. 260. F.E. 23:401.—A universal favorite. Hardy. Much used in old-fashioned gardens as edging for beds. There are double-fl. forms. A more continuous-blooming form is catalogued as var. *semperflorens*.

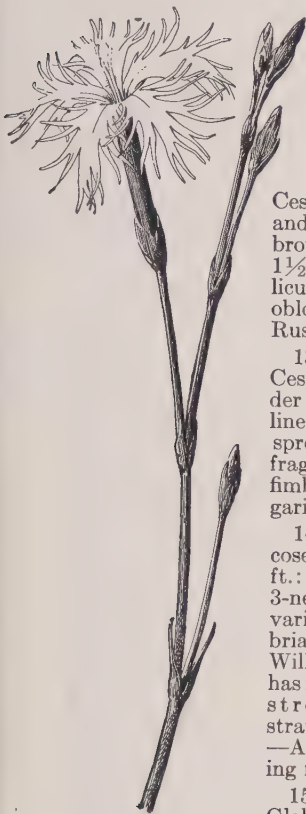

10. *arenarius*, Linn. Cespitose, glabrous, 1 ft. or less, the sts. simple or forked, slender, 1-3-fl.: lvs. elongate-linear, keeled, obtuse, fascicled, spreading: fls. white, fragrant; petals much cut beyond the middle; calyx purplish, the teeth ovate-lanceolate.

Dalmatia to Finland. G. 26:433.—Var. *glauus*, Blocki, connects this species with No. 9.

DD. *Teeth of calyx acuminate or attenuate.*

11. *monspessulanus*, Linn. Sts. terete, glabrous, branching, 12–20 in.: lvs. linear, acuminate, plane, spreading but strict, 5-nerved: fls. solitary or 2 or 3 together, showy, odorless; petals rose, rarely white, cut or fimbriate; calyx attenuated at top, the teeth 7-nerved. Spain to Caucasus.

1252. *Dianthus superbus*. ( $\times \frac{1}{2}$ )

lance-linear, acute, 3–5-nerved, rather soft, plane: fls. very fragrant, in a lax forked panicle; petals lilac, dissected below the middle. Norway to Japan and Spain. Variable. B.M. 297.—A handsome species; garden forms are sometimes offered.

cc. *Petals only dentate (except perhaps in some garden forms).*

16. *càsius*, Smith. CHEDDAR PINK. Cespitose, glabrous, glaucous: sts. 12 in. or less, simple, or forked above, 4-angled, 1–2-fld.: lvs. lance-linear, plane, 3-nerved, the cauline acute and keeled: fls. showy, fragrant, the petal-limb rose-colored, obovate-cuneate and irregularly toothed. Eu. G.C. III. 44:214. Gn. 64, p. 236.—Runs into several forms.

17. *sylvêstris*, Wulf. (*D. virgineus*, Hort.). Cespitose, slender, 1 ft. high, the st. simple or somewhat branched, angular-compressed and bearing 1–3 odorless fls.: lvs. tufted, linear and sharp-pointed, scabrous on the margins: fls. rather small, red, the petals obovate-cuneate and shallow-toothed. Spain to Greece and Austria.—Very variable. Pretty perennial border plant. Var. *frigidus*, Williams (*D. frigidus*, Kit.) is a dwarf Hungarian form.

18. *attenuatus*, Smith. Cespitose, glaucous, woody at base, the sts. diffuse and tortuose, 20 in.: lvs. linear, acute, plane, 3-nerved: fls. small, solitary or twin but disposed in a lax panicle, odorless, rose-colored; petal-limb oblong. Eu.

12. *squarrôsus*, Bieb. Cespitose: sts. terete, slender and squarrosely few-fld., glabrous, more or less branching,  $1\frac{1}{2}$ –2 ft.: lvs. linear, acute, canalliculate, recurved: fls. rose; petals oblong, pinnately many-parted. Russia, Siberia.

13. *petrêus*, Waldst. & Kit. Cespitose, glabrous, the sts. slender and simple, 1 ft. or less: lvs. linear-lanceolate, acute, keeled, spreading, 3-nerved: fls. white, fragrant; petal-limb obovate, fimbriate but not bearded. Bulgaria, Austria. B.M. 1204.

14. *fimbriatus*, Bieb. Suffruticose, glabrous, the sts. simple, 1 ft.: lvs. linear, acute, appressed, 3-nerved, plane or keeled: fls. variable, rose-colored, much fimbriate, bearded. Var. *orientâlis*, Williams (*D. orientâlis*, Donn), has fls. with linear-cuneate petals, strongly imbricate obovate straw-colored bracts. B.M. 1069.—A very variable species, ranging from Portugal to Thibet.

15. *supêrus*, Linn. Fig. 1252. Glabrous, light green: sts. 10–20 in., dichotomous and branched at top, terete and slender: lvs.

19. *Caryophyllus*, Linn. CARNATION. CLOVE PINK. PICOTEE. GRENADINE. Figs. 801–818. Plate XXII. Cespitose, glabrous, 1–3 ft., the sts. hard or almost woody below, the nodes or joints conspicuous: lvs. thick, long-linear, very glaucous, keeled, 5-nerved, stiffish at the ends: fls. mostly solitary, showy, very fragrant, rose, purple or white; calyx-bracts 4, very broad, abruptly pointed. B.M. 39 (Bizarre Carnation); 1622 (var. *imbricatus*); 2744 (Picotees).—Generally supposed to be native to the Medit. region, but Williams gives its geographical limits as “north and west Normandy” and “south and east Punjab” (northwestern Hindoostan). In Eu. it is largely grown as an outdoor pink, but in this country it is chiefly known as the greenhouse carnation. The American forcing type (which may be called var. *longicaulis*) is distinguished by very long stems and a continuous blooming habit; it is here the carnation of commerce. Garden varieties of *D. Caryophyllus* are numberless, and they often pass under Latinized names (*D. punctatus*, Hort., is one of these names). See *Carnation*. The carnation has been long in cult. The bloom is now very variable in size, form and color; originally probably pale lilac. Fragrant.

BB. *Calyx-bracts half the length of the calyx, mostly narrow-pointed, more or less spreading at the tips: lvs. short and spreading, the radical ones obtuse or nearly so.*

20. *deltoides*, Linn. MAIDEN PINK. Fig. 1253. Densely tufted, 6–10 in., blooming in spring and early summer, creeping: sts. ascending, forking, with solitary fls. on the branchlets: st.-lvs. an inch long, linear-lanceolate, sharp-pointed: fls. small ( $\frac{1}{2}$ – $\frac{3}{4}$  in. across), the petals toothed, deep red with a crimson eye, the petals bearing an inverted V-shaped pocket at their base (whence the name *deltoides*), fragrant. Scotland to Norway and Japan. Gn. 66, p. 224. G.M. 55:28. G.W. 14, p. 181.—One of the prettiest border pinks, making neat mats of foliage and bearing profusely of the little bright fls. There is a white-fld. variety.

21. *alpinus*, Linn. More or less cespitose, very dwarf, the 1-fld. slender sts. rarely reaching more than 3–4 in. high, more or less prostrate: foliage dark shining green, the lvs. linear or lance-linear, those on the st. keeled and strict: fl. 1 in. or more across, odorless, deep rose or purplish and crimson spotted, a darker ring around the eye. Russia to Greece and Swiss Alps. B.M. 1205. Gn. 26:184; 47, p. 292; 45, p. 53. Gt. 4:110. G.W. 8, p. 14.—One of the choicest of alpine and rock-work plants. Var. *repens*, Regel (*D. repens*, Willd.), of Siberia and Alaska, has a single root and procumbent sts. branched from near base: fls. purple; calyx somewhat inflated,  $\frac{1}{2}$  in. long. Apparently not cult. This is kept as a distinct species by some.

22. *versicolor*, Fisch. Glabrous, the sts. 10–12 in., terete, paniculately branched: lvs. narrow-linear, plane, those on the st. becoming scale-like: fls. loosely paniculate, the petal-limb obovate-cuneate, red-spotted above and greenish yellow beneath; calyx-teeth lanceolate, acute. Altai Mts., Siberia.

23. *callizônus*, Schott & Kotschy. Smooth and glaucous, the sts. terete, 1-fld., 12–16 in.: lvs. canalliculate, 3–5-nerved, the radical linear-lanceolate and acute, the cauline lance-linear and acuminate: petal-

1253. *Dianthus deltoides*.

limb obovate-cuneate, purple-spotted above, and with a zone at the center, rose-colored beneath; calyx purple, the teeth lanceolate-acuminate. S. E. Eu. Gn. 64, p. 298; 66, p. 54; 70, p. 275.

BBB. *Calyx-bracts leafy and spreading.*

24. *glaciâlis*, Haenke. Three to 4 in. high, the 4-angled sts. tufted and 1-2-fld.: lvs. green, linear-lanceolate, pointed, those on the st. linear-acute and strict or recurved, 3-nerved; fls. small and odorless, red-purple; the petals toothed, yellowish beneath, contiguous; bracts 2-4. Mts. of S. Eu. G.C. II. 21:809.—A pretty species, but difficult to establish. Grown among alpine plants. Var. *Frèynii*, Williams (*D. Frèynii*, Vandas). Lvs. rather soft, keeled, the lateral nerves obscure; sts. usually 1-fld.: calyx-teeth ciliate. Var. *neglectus*, Williams (*D. neglectus*, Loisel). Lvs. plane; fls. rarely twin; bracts 4: petals separate. G.C. III. 49:415. Gn. 76, p. 339. Gn.W. 20:711.

25. *chinensis*, Linn. (*D. sinensis*, Hort.).

Fig. 1254. Cespitose, glabrous, more or less creeping at base: st. forking, angled and more or less grooved, pubescent: lvs. broad and nearly flat or slightly trough-shaped, 3-5-nerved: fls. large, solitary or more or less clustered, pink or lilac; the petals (at least in the wild) barbed or hairy toward the base; calyx-bracts 4, in some cult. vars. short. China and Japan; but recent authorities consider a European pink to be but a form of it, and thereby extend its range west to Portugal. B.M. 25. The Amoor pink (*D. dentosus*, Fisch.) is a form known as var. *macrosepalus*, Franch.: it is a hardy border plant, 1 ft. high, with bright red fls. and a spot at base of each petal. Var. *âsper*, Koch (*D. Séguieri*, Auth.). has fls. in panicles, and the bracts squarrose-spreading: the European form of the species. *D. semperflorens*, Hort., is a hardy perennial form, 12-18 in., with silvery foliage and deep pink, red-eyed, fragrant fls. *D. chinensis* has given rise to a beautiful and variable race of garden pinks, var. *Heddewigii*, Regel (*D. Heddewigii*, Hort.). These are extensively grown from seeds, and are practically annuals, although plants may survive the winter and give a feeble bloom in the spring in mild climates. The fls. are scarcely odorous. They are single and double, of many vivid colors; and many of the garden forms have bizarre markings. Gt. 7:328. G. 2:537. In some forms, var. *laciniatus*, Regel (*D. laciniatus*, Hort.), the petals are slashed and cut. G. 2:538. G.Z. 6:1. *D. imperialis*, Hort., is a name applied to a strain with strong habit and rather

tall growth, mostly double. *D. diadematus*, Hort., is another garden strain. G. 2:538. *D. cinnamatus*, Lem., is a red form with shredded petals. I.H. 11:388. *D. hybridus*, Hort., is another set. This name (*D. hybridus*) is also applied to a *dentosus*-like form, which some regard as a hybrid of *D. dentosus* and some other species. A recent race of the garden pinks, with narrow petals and a star-like effect, is var. *stellaris*, (*D. stellaris*, Hort.). For portraits of garden pinks, see B.M. 5536. F.S. 11:1150; 12:1288-9; 13:1380-1. Gn. 49:82.—The garden pinks are of easy cult. Seeds may be sown in the open where the plants are to stand, but better results are obtained, at least in the N., if plants are started in the house. Plants bloom after the first fall frosts. They grow 10-16 in. high, and should be planted 6-8 in. apart. They are very valuable for borders and flower-gardens. Species-names now referred to *D. chinensis* are *D. caucasicus*, Sims, *D. ibericus*, Willd., *D. ruthenicus*, Roem., *D. montanus*, Bieb., *D. collinus*, Waldst. & Kit., representing the European extension of the species.

26. *latifolius*, Hort. Plant 6-12 in. high, of doubtful origin, but in habit intermediate between *D. chinensis* and *D. barbatus*. Fls. large, double, in close clusters or even heads, in good colors: lvs. oblong-lanceolate.—A good border plant; perhaps a hybrid.

*D. arboreus*, Linn. 3-4 ft., glabrous and glaucous, with a woody trunk, linear-acute canaliculate 3-nerved lvs., and showy rose-colored fragrant fls. in a dense corymb. S. E. Eu. G.C. III. 43:52. This species is one of the sub-shrubby group of *Dianthus*, comprising also *D. fruticosus*, Linn. (of the Grecian Archipelago), *D. Bisignani*, Tenore (of Tunis and Naples), and others. *D. suffruticosus*, Willd., probably belongs with the last.—*D. call-alpinus*, Hort. Hybrid of *D. callizonus* and *D. alpinus*. G.M. 47, p. 408.—*D. diutinus*, Kit. Allied to *D. barbatus*: glabrous: sts. simple, 12-18 in., 4-angled: fls. pale red, 6-8 together in a head, the petals barbed. Hungary, Servia. Rockery.—*D. fragrans*, Bieb. Cespitose, glabrous: sts. 10-16 in., simple, or branched above: lvs. elongated-linear, acuminate, 3-5-nerved: fls. fragrant, the limb white suffused with rose, petals beardless. Caucasasia, Algeria.—*D. gracilis*, Sibth. More or less woody at base, glabrous and glaucous, the sts. 14-18 in. and simple and slender: lvs. linear-acute, strict, 3-nerved: fls. rose, paler beneath, 2-3 in a cluster. Balkans.—*D. graniticus*, Jord. Sts. simple, scabrous below and glabrous above, slender, 4-angled, 6 in.: lvs. linear-acute, 3-nerved: fls. solitary or in pairs, purple. France, Rockery.—*D. japonicus*, Thunb. Glabrous perennial, with simple sts. 20 in.: lvs. ovate-lanceolate, acute, canaliculate, twisted at base: fls. 6-8 in a head, red. Japan, Manchuria.—*D. microlepis*, Boiss. Very dwarf, caespitose, glabrous: lvs. scale-like: fls. rose-colored (varying to white). Balkans. A marked little alpine.

L. H. B.

1254. *Dianthus chinensis*. (X $\frac{1}{2}$ )

**DIAPENSIA** (ancient name of obscure application). *Diapensiaceæ*. Two alpine-arctic species, one nearly circumpolar and one Himalayan, the former at least sometimes transferred to alpine gardens and rockeries. *Diapensias* are very small compact tufted evergreen more or less woody perennials, with small entire coriaceous crowded lvs.: corolla 5-lobed, bell-shaped; calyx inclosing the caps.; stamens 5, affixed in the corolla, the filaments broad; ovary 3-celled; fls. solitary on peduncles that project above the dense lf.-rosettes (or the peduncle projected, at least in fr.), white or rose-purple. *D. lappônica*, Linn., on mountain summits in New England and N. Y., and distributed northward to the arctic, forms dense cushion-like tufts, 1 or 2 in. high, with white fls. on peduncles that become 1 or 2 in. long; a very interesting alpine, but seldom grown. B.M. 1108. *D. himalaica*, Hook. f. & Thom. Densely tufted: lvs. somewhat acute, very short: fls. white or rose-red, subsessile, the corolla-tube twice the length of the calyx. Sikkim, 10,000-14,000 ft.

L. H. B.

**DIÁSCIA** (to adorn, Greek, having regard to the attractive flowers). *Scrophulariaceæ*. Low and slender herbs, mostly annual, one of which is recently grown in flower-gardens.

Leaves usually opposite: fls. mostly violet or rose-color in general effect, in racemes or fascicles at the end of the st. or branches; calyx 5-parted or -lobed; corollatube very short or none; limb 2-lipped, the upper lip 2-lobed and lower 3-lobed, all the lobes being broad and flat, 2 of the fauces being projected into spurs; stamens 4, didynamous; style filiform: fr. a globose or elongated dehiscent many-seeded caps.—Probably 25 or more species in S. Afr.

**Bárberæ**, Hook. f. Fig. 1255. Annual: st. erect, 1-1½ ft., square, green and glabrous: lvs. ovate, blunt, obtusely serrate, petioled or the upper ones sessile: fls. several to many in an erect terminal raceme, on slender glandular pedicels; calyx deeply 5-lobed; corolla ½ in. across, rose-pink with yellow green-dotted spot in throat, the 2 upper lobes small and nearly orbicular, the lateral twice larger, and the lower one much larger and obscurely 4-angled, the spurs cylindrical and about as long as lower lobe; filaments glandular. B.M. 5933. Gt. 50, p. 639.—A very attractive little plant, of simple cultural requirements, blooming freely in summer. It also makes a good pot-plant for indoor use. Half-hardy annual. Pink and orange shades are advertised.

L. H. B.

**DIASTÈMA** (two stamens). *Gesneriaceæ*. Dwarf warmhouse plants of Trop. Amer. (about 20 species), allied to *Dicyrta*, *Achimenes* and *Isoloma*, and requiring similar treatment; differs from former two in having 5 distinct glandular parts to the disk rather than annular, and from *Isoloma* in the narrower parts of the disk, plants weak, fls. pale, white or purplish, and in the short or nearly globular anther-cells, and other features: summer-flowering. *D. ochroleucum*, Hook., has yellowish white fls.; corolla somewhat swollen at base: lvs. ovate, acute, hairy, coarsely serrate, on hairy purplish erect sts. 1-2 ft. high. Colombia. B.M. 4254. *D. pictum* is offered abroad, but its identity is in doubt; see *Isoloma*.

L. H. B.

**DICÉNTRA** (Greek, *dis*, *kentron*, two-spurred, but originally misprinted *Diclytra*, and then supposed to be *Dielýtra*). *Fumariaceæ*; by some this family is combined with *Papaveraceæ*. Charming hardy perennial plants with much-cut foliage, and clustered attractive flowers of interesting structure.

Herbs of various habit, erect, diffuse or climbing, often stemless, with rhizome horizontal and branching or more or less bulbous: lvs. ternately compound or dissected: fls. rose-red, yellow or white in attractive

racemes, very irregular, with 4 petals cohering into a heart-shaped or 2-spurred apparently gamopetalous corolla (the 2 outer petals oblong with spreading tips and spurred or saccate at base, the inner 2 narrow and clawed and crested or winged and more or less united over the stigma); sepals 2, very small, scale-like; stamens 6, in sets of 3; pistil 1-celled, with a 2-4 crested and sometimes 2-4-horned stigma, ripening into an oblong or linear 2-valved caps. bearing crested seeds; pedicels 2-bracted.—About 15 species, in N. Amer., W. Asia and the Himalayas. The names *Bikukulla* (or *Bicuculla*) and *Capnorchis* are older than *Dicentra*, but are rejected by the "nomina conservanda" list of the Vienna code.

The squirrel-corn and dutchman's breeches are two of the daintiest native springtime flowers; and the bleeding-heart is one of the choicest memories of old-fashioned gardens: it is also the most widely cultivated of all the plants of this delightful order. Though long known to herbaria, plants of bleeding-heart were not introduced to western cultivation from Japan until the late forties of last century. Robert Fortune saw it on the Island of Chusan, where he also got *Diervilla rosea* and the "Chusan daisy," the parent of pompon chrysanthemums. The first live plants seen in England flowered in May, 1847. It rapidly spread into every garden in the land, and is now rich in home associations. It is an altogether lovely plant. The species of *Dicentra* may be classed as caulescent and acaulescent. The stemless kinds send up their short scapes directly from the ground, as *D. Cucullaria*, *D. canadensis*, *D. formosa*, *D. eximia*. The species with leaf-bearing stems are such as *D. chrysantha* and *D. spectabilis*. In the species here described the flowers are nodding except in *D. chrysantha*.

*Dicentras* are easily cultivated in borders and wild gardens. Two or three kinds can be readily secured from the woods in the East. Effort should be made to reproduce the natural conditions, especially the degree of shade. They like a rich light soil. Propagation is by dividing crowns or roots. The forcing of bleeding-hearts, though practically unknown in America, is said to be commoner in England than outdoor culture. The forcing must be very gentle and the plants kept as near the glass as possible. It is best to have fresh plants each year, and return the forced ones to the border. None of the species is much cultivated with the exception of the bleeding-heart (*D. spectabilis*).

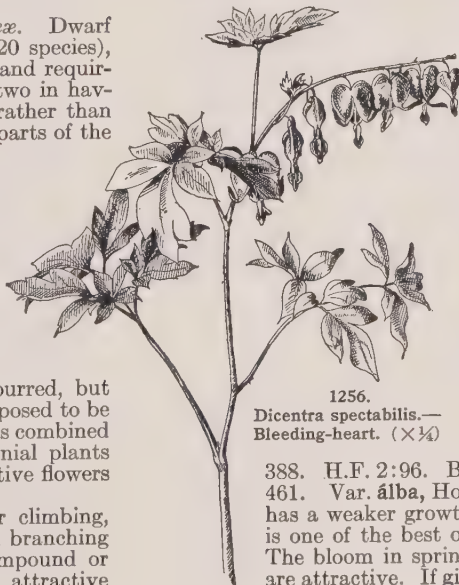

A. Fls. rose-purple.

B. Racemes simple.

*spectabilis*, Lem. (*Dielýtra spectabilis*, Don). BLEEDING-HEART. Fig. 1256. Height 1-2 ft.: lvs. and fls. broadest of the group, the ultimate segms. obovate or cuneate: fls. large, deep rosy red; corolla heart-shaped; inner petals white, protruding. Japan. F.S. 3: 258. Gn. 40:198; 60, p. 375; 70, p. 192. Gn.W. 23: suppl. July 14. G. 2:375; 26:142; 27:112. G.M. 49:718; 51:160. G.W. 5, p. 388. H.F. 2:96. B.M. 4458. R.H. 1847: 461. Var. *álba*, Hort., the white-fl. form, has a weaker growth. The bleeding-heart is one of the best of flowering perennials. The bloom in spring and also the foliage are attractive. If given room and moisture,

1255. *Diascia Barberæ*.  
(Plant  $\times \frac{1}{3}$ )

1256.  
*Dicentra spectabilis*.—  
Bleeding-heart. ( $\times \frac{1}{4}$ )

the plant will continue to be attractive as a foliage mass till late summer.

BB. *Racemes compound.*

**eximia**, Torr. Stemless, glabrous and somewhat glaucous, 1-2 ft., from a scaly rootstock: ultimate lvs. segms. broadly oblong or ovate, the lvs. being ternately parted: scape about equaling the lvs.; fls. rose or pink, heart-shaped, tapering to a neck, inner petals protruded. Rocks of W. N. Y. and mountains to Ga. Var. **multi-pinnata**, Hort., has lvs. more finely cut, making a very handsome foliage plant.

**formosa**, Walp. Fig. 1257. Stemless, with a fleshy and spreading rootstock: lvs. very long-stalked, biterminately compound, the segms. cleft or pinnatifid.: scapes about 2 ft., somewhat exceeding the lvs., naked; fls. in a terminal cluster of short and bracted racemes, rose-purple, the corolla ovate-cordate, the petals all united to above the middle, the inner petals scarcely protruding. Cent. Calif. to Brit. Col. A.F. 21:459. Mn. 8:17. B.M. 1335 (as *Fumaria formosa*).

1257. *Dicentra formosa*.  
( $\times \frac{1}{2}$ )

AA. *Fls. chiefly white.*

**canadensis**, Walp. (*Dielytra canadensis*, Don). SQUIRREL-CORN, from the scattered little tubers resembling grains of maize. Fig. 1258. Stemless, fragile: lvs. finely cut, glaucous, the segms. linear and abruptly pointed: raceme simple, few-fl.; fls. white, tipped with rose; corolla merely heart-shaped, the spurs being short and rounded; crest of the inner petals conspicuous, projecting. Nova Scotia to Mich., to N. C. and Mo. and Neb., but chiefly northward in the vegetable mold of rich woods. B.M. 3031.

**Cucullaria**, Bernh. (*Dielytra Cucullaria*, Don). DUTCHMAN'S-BREECHES. Fig. 1259. Easily told from *D. canadensis* by its loose, granular cluster of tubers, forming a bulb-like body: lvs. finely cut, little or not at all glaucous: racemes simple, few-fl.; fls. white, tipped creamy yellow; corolla not heart-shaped, the spurs longer and divergent; crest of the inner petals minute. Nova Scotia to Ga. and Mo., and also along the Columbia River (the western form differing in having shorter and rounded spurs). I.H. 6:215. Mn. 6:41. A.G. 13:516. B.M. 1127 (as *Fumaria Cucullaria*).

AAA. *Fls. yellow.*

**chrysantha**, Walp. GOLDEN EARDROPS. Pale and glaucous, with leafy sts. 2-3 ft. high: lvs. bipinnate, 1 ft. or more long, segms. narrow: infl. thyrsoid paniculate; fls. numerous, as many as 50 in a thyse, erect, golden yellow; corolla linear-oblong; outer petals hardly larger than the inner, the tips soon recurving to below the middle, all distinct. Dry hills of the inner Coast range. Calif. B.M. 7954. F.S. 8:820 (as *Capnorchis chrysantha*).—Rare in cult.

*D. torulosa*, Hook. f. & Thoms., of the Himalayan region, has been intro. abroad. It is an annual climber, 10-16 ft.: lvs. attractively cut: fls. 6-8 together, yellow: fr. red.

L. H. B.†

**DICHORISANDRA** (compounded of Greek words referring to the division of the stamens into two series). *Commelinaceae*. Tropical perennial herbs, with handsome foliage, often beautifully variegated, and rich blue flowers borne in thyse-like panicles.

Stems simple or branched, erect or partially scandent, the lvs. sheathing at the nodes: lvs. entire, sessile or petiolate, mostly long: sepals 3, distinct, ovate or oblong, green or colored, not equal; petals 3, distinct, wider than the sepals; stamens 6 or 5; ovary sessile, 3-celled: fr. an ovate-3-angled 3-valved caps., few-seeded.—About 30 species in the American tropics.

The dichorisandras are usually handled as warmhouse subjects, although some of them may be plunged in the open ground south of Philadelphia. *D. thyrsiflora* is a satisfactory plant of unusual and interesting appearance, which requires little attention when once well established, and may be relied upon to flower regularly year after year. It needs careful repotting every year at first until a good-sized pot (say 8-inch) is well filled with roots. It then throws up a strong shoot each year about 5 or 6 feet high, unbranched, and with perhaps 8 or 9 leaves near the top. The handsome thyse of blue flowers gives a color that is rare in the greenhouse. This plant may be the only representative of its interesting order in a private collection. It is willing to be crowded into the background, where its bare stem is hidden, and where the light may be poorest. The stem dies down in the winter time, when water should be gradually withdrawn. Water should be given liberally during the growing season. Of the foliage plants of this genus, *D. mosaica* is commonest. It is dwarfer, and does not flower so regularly. (Robert Shore.)

A. *Foliage not variegated.*

**thyrsiflora**, Mikan. Simple or nearly so, stout, 3-6 ft.: distinguished by its large lvs., which are lanceolate, narrowed into a distinct petiole, glabrous, 6-10 in. long, 2 in. wide, green on both sides: st. about 3 ft. high, scarcely branched, robust, glabrous: racemes subpanicked, pubescent; petals dark or light blue; sepals glabrous, blue or somewhat herbaceous. Brazil. B.R. 682. L.B.C. 12:1196. P.M. 3:127. G. 27:569. J.H. III. 43:262.

AA. *Foliage variegated.*

**mosaica**, Lind. (*D. musaica*, Koch & Lind.). St. erect, simple, stout, spotted: distinguished by its large, broadly elliptical lvs., which are roundish at

1258. Leaf of  
*Dicentra canadensis*.  
—Squirrel-corn.

the base, sessile, glabrous, about 6 in. long, 3-4 in. wide, with a short, sharp, rather abrupt point: st. unbranched, robust, spotted; raceme short, densely thyrsoid; sepals white or greenish. *Gt.* 1868:593. *F.S.* 16:1711.—Its chief beauty is the mosaic appearance of the foliage, due to numberless short transverse whitish lines, which do not pass by the longitudinal veins of the lf. The under side of the lvs. is a rich purplish color. *Var. gigantæa*, Hort., a large form, has been offered.

*Var. undata*, Miller (*D. undata*, C. Koch & Lind.). Foliage without any mosaic appearance, the variegation being entirely longitudinal. Each parallel vein

1259. *Dicentra Cucullaria*.—Dutchman's Breeches.

lies in the middle of a long, whitish band extending the full length of the lf. *F.S.* 17:1763. *G.W.* 3, p. 159.

*D. acutis*, Cogn. Stemless: lvs. in a rosette, almost sessile, narrowly oblong, wavy, acutish, short-cuneate at the base, sparsely pilose on both sides; panicles terminal, sessile, much shorter than the lvs. Brazil. *I.H.* 41:19. Handsomely variegated with countless short longitudinal lines.—*D. albo-marginata*, Lind. St. 3-4 ft.: lvs. lanceolate, acuminate, attenuate to base, glabrous: raceme peduncled, 2 in. long, dense; petals dark blue, white at base; sepals white. Brazil. *G.W.* 4, p. 307.—*D. angustifolia*, Lind. & Rod. St. purple, spotted green: lvs. oblong-lanceolate, sessile, glabrous, roundish at the base, acute, about 6 in. long, 2 in. wide at the middle, purple below, marked above with short transverse white lines. Ecuador. *I.H.* 39:158.—*D. leucophthalmos*, Hook., differs in having radical inf., its fls. lying flat on the ground. Lvs. elliptic, acuminate, green on both sides: fls. blue, with a white eye; stamens 6. Brazil. *B.M.* 4733. *J.F.* 4:428.—*D. ovalifolia*, Presl. Lvs. oval, sessile, acuminate, glabrous, the upper ones oblong-lanceolate; panicle wide-branched. Nicaragua to Colombia.—*D. oxyptala*, Hook., is instantly recognized by its acute petals, which are purple. Lvs. green on both sides. Brazil. *B.M.* 2721.—*D. picta*, Lodd., has narrower petals than usual, with a white spot at the base, but is told from all others here described by the irregular blotches of purple on the upper side of the lvs. The purple is the same color as that on the under surface. Brazil (?). *B.M.* 4760. *L.B.C.* 17:1667.—*D. Regina*, Hort. = *Tradescantia Regina*, Lind. & Rod., intro. about 20 years ago by a firm of Continental Eu.—*D. Saundersii*, Hook., differs from all others here described in the extreme density of its head-like inf. Lvs. green on both sides, lanceolate; sepals white, tinged blue. Brazil. *B.M.* 6165.—*D. Sibbertii*, Hort. A little-known plant with white midrib and margins; probably a form of *D. ovalifolia*.—*D. thysiana* = *Palisota*.

WILHELM MILLER.

L. H. B.†

**DÍCHROA** (Greek, *dis*, two, and *chros*, color). Syn. *Adámia*. *Saxifragaceæ*. Rare greenhouse shrub in habit resembling a *Hydrangea*, with violet-blue fls. in a pyramidal panicle a foot across, and handsome blue berries. Lvs. persistent, opposite, stalked, narrow, tapering both ways, serrate; panicles terminal, many-fl.; fls. blue, lilac, or violet; petals 5 or 6, valvate; styles 3-5, club-shaped; seeds numerous, small. The

genus has only 1 species, in the Himalayas, Malaya, and China. It is sometimes considered to be bitypic, but the other species, *D. pubescens*, Miq., is considered by Koorders (*Exkursionoflora von Java*) to be probably a true *Hydrangea*.

*febrífuga*, Lour. (*Adámia versicolor*, Fortune. *Cyanitis sylvatica*, Reinw.). Later writers also include *Adámia cyanea*, Wall., which Lindley distinguished by its smaller lvs. and fls., 5 petals, and 10 stamens, while *A. versicolor* had 7, or sometimes 6 petals, and 20 stamens. Plants may still be cult. under the name of *A. cyanea*, but it cannot be stated here how distinct they are for horticultural purposes. A somewhat virgate shrub 5-9 ft. tall, with lanceolate or obovate-lanceolate lvs. to 8 in. long, glabrous except on the nerves; petals less than  $\frac{1}{4}$  in. long. Clarke states that the Chinese varieties have larger fls. than the Indian forms. Occurs in the temperate Himalayas from 5,000-8,000 ft. *B.M.* 3046. *P.M.* 16:322.

WILHELM MILLER.

L. H. B.†

**DICHROPHYLLUM**: *Euphorbia*.

**DICHRÓSTACHYS** (two-colored spikes). *Leguminosæ*. Stiff shrubs, with bipinnate lvs. and small leathery lfts. and very small polygamous fls. in spikes, sometimes mentioned as useful for cult. in warmhouses. The species are few, in Trop. Asia, Afr., and Austral. Fls. in the upper part of the spike perfect, those of the lower part bearing 10 long filiform staminodia; corolla not papilionaceous, comprising 5 strap-shaped petals that are more or less united at base; stamens 10 in the perfect fls., free, slightly exerted; pod narrow, compressed, mostly or nearly indehiscent. *D. platycarpa*, Welw., is or has been in cult.: a slender spiny tree, 10-15 ft. high; pinnæ 10-18 pairs, the lfts. 1-2 lines long and very narrow; spikes usually shorter than the lvs.: pod twisted, 2-4 in. long, about 1 in. broad. Guinea. *D. nitans*, Benth. (*Cailliea Dichrostachys*, Guill. & Perr.), has been intro. in S. Calif.: spiny, much contorted shrub or small tree: lvs. glabrous or pubescent, acacia-like; pinnæ 5-10 pairs; lfts. 10-20 or more pairs, sessile, linear or linear-oblong, rarely as long as  $\frac{1}{2}$  in.: fls. in dense axillary twin or solitary spikes, the upper ones sulfur-yellow and the lower ones rosy lilac: pod twisted,  $\frac{1}{2}$  in. or less broad. Cent. Afr.

L. H. B.

**DICKSONIA** (named for James Dickson, an English botanist, 1738-1822). *Cyatheaceæ*. Tree ferns of greenhouses.

Plants with a distinctly 2-valved inferior indusium, the outer valve formed by the apex of the lf-segm.—A small genus, mostly of the southern hemisphere. For *D. pilosiuscula*, *D. punctilobula* and *D. Smithii*, see *Dennstaedtia*. For *D. Schiedeii* and *D. regalis*, see *Cibotium*. These are only two of several confusions of species which have been called Dicksonia, but really belong in other genera. Modern fern students are now reaching the conclusion that Dicksonia is not only very distinct from the genus *Cyathea* and its relatives, but belongs in a distinct family.

Dicksonias are amongst the most important tree ferns, both for their beauty and because of their relative hardiness. In their native countries some of them are occasionally weighted with snow, and *D. antarctica* has to endure frosts. They can be grown in coolhouses, and should be tried southward outdoors in sheltered places. Their trunks are more fibrous than those of most tree ferns, and hence more retentive of moisture, so that they need less care. A good trunk produces thirty to forty fronds a year, and retains them until the next set is matured, unless the trees suffer for moisture in winter. Although they rest in winter, the fronds soon shrivel up if the trunks are allowed to get too dry. Dicksonias should have their trunks thoroughly watered twice a day during the growing season. These waterings

should be gradually decreased until winter, when the trunks should be kept merely moist all the time. Only in the hottest summer days is slight shade needed. It is a pity to grow tree ferns in pots, but if this must be done several principles should be observed. The lapse of a single day's watering will often cause serious damage. As a rule, the pots should be of the smallest size consistent with the size of the trunk. Three or 4 inches of soil all around the trunks are enough. The above points are taken from Schneider's "Book of Choice Ferns;" see also the discussion of tree ferns under *Ferns*, Vol. III.

**antártica**, Labill. Lf.-stalks short, the scales dense, dark purplish brown; lvs. 5-6 ft. long, the middle pinnæ 12-18 in. long; segms. oblong, the sterile incised. Austral. and Tasmania. G.C. III. 9:81.—Trunk sometimes 30-35 ft. high. A very useful decorative plant.

**squarrosa**, Swartz. Lf.-stalks short, the scales hair-like, light colored; lvs. 3-4 ft. long, the pinnæ 9-15 in. long; segms. lanceolate, the sterile toothed, the ribs scabrous. New Zeal. and Chatham Isl.

L. M. UNDERWOOD and WILHELM MILLER.

**DICLIPTERA** (named in allusion to the 2-celled winged caps.). *Acanthaceæ*. Pubescent or hirsute annual or perennial herbs or sub-shrubs, with red, violet or blue bracted flowers in terminal or axillary clusters, in the tropical parts of the world, 1 or 2 of which may sometimes occur in the trade. Lvs. opposite, entire, the plant usually evergreen; corolla-tube, slender, often somewhat expanded above; limb 2-lipped, the lips narrow; stamens 2, on the throat. **D. Niederleiniana**, Lind., has been recently intro. abroad from Argentina: sub-shrub: lvs. oval, to 3 in. long, petioled, rounded at apex, densely pubescent: fls. about 1¼ in. long, several crowded in a terminal paniculate cyme. **D. Tweediana**, Nees, of Uruguay, is a showy perennial with orange-red fls. and oblong-obtuse lvs. There are probably 75 species of *Dicliptera*. Very likely the horticultural names are confused as between this genus and others.

L. H. B.

**DICLÝTRA**: An ancient typographical error for *Dielytra*. See *Dicentra*.

**DICTÁMNUS** (old Greek name, supposed to indicate foliage like the ash: hence *Fraxinella*, diminutive of the Latin *Fraxinus*, an ash). *Rutaceæ*. GAS-PLANT. BURNING-BUSH. *FRAXINELLA*. DITTANY. A hardy perennial herb.

Stout plants woody at the base: lvs. alternate, odd-pinnate, the lfts. ovate, serrulate and pellucid-punctate: fls. showy, white or rose, on bracted pedicels; petals 5, the lower one declined; disk thickish, annular; stamens 10, declined; ovary deeply 5-lobed, 5-celled, hispid, becoming a hard 5-divided caps., each division or separate part being 2-3-seeded.—One variable species, native from S. Eu. to N. China.

This genus includes an old garden favorite which has a strong smell of lemon, and which will give a flash of light on sultry still summer evenings when a lighted match is held under the flower-cluster and near the main stem. It is one of the most permanent and beautiful features of the hardy herbaceous border. Instances are known in which it has outlived father, son and grandson in the same spot. It thrives in the sun.

The gas plant makes a sturdy, bold, upright growth, and a clump 3 feet high and as much in thickness makes a brave sight when in flower. A strong, rather heavy soil, moderately rich, is best for these plants. They are not fastidious as to situation, succeeding as well in partial shade as when fully exposed to the sun, and drought will not affect them when once fairly established. Old strong clumps are good subjects as isolated specimens on a lawn, and a large patch, planted in the border, is not only effective while in full flower, but the dark,

persistent foliage is ornamental throughout the season. It is not advisable to disturb the plants very often, as they improve with age, producing taller flower-stems and more of them as they grow older. They are excellent for cutting, especially the white variety. Propagation is accomplished with difficulty by division, but easily by seeds, which are sown in the open ground in fall as soon as ripe, and covered an inch or so. They will germinate the next spring, and, when two years old, the seedlings may be removed to their permanent positions, where they will flower the following year. (J. B. Keller)

**álbus**, Linn. (*D. Fraxinella*, Pers. *Fraxinella álba*, Gaertn. *F. Dictamnus*, Moench). A vigorous, symmetrical, hardy herb, with glossy leathery foliage surmounted by long showy terminal racemes of good-sized fragrant fls.: lvs. alternate, odd-pinnate; lfts. ovate, serrulate, dotted with oil-glands: fls. white. G.C. III. 34:409. Gn. 35:458; 68, p. 73; 75, p. 381. G. 13:25. A.F. 5:328. Gng. 5:321. Var. **purpureus**, Hort., has large dark-colored fls. Var. **rúbra**, Hort., has rosy purple fls., the veins deeper colored. Var. **gigantæus**, Hort. (*D. gigantæus*, Hort.). Plant large. Var. **caucásicus** (*D. caucásicus*, Hort.), is a giant form with racemes twice the length of those of the common kind and standing well above the foliage. R.B. 32, p. 253. Perhaps the same as var. *gigantæus*.

WILHELM MILLER.

L. H. B.†

**DICTYOGRÁMMA**: *Coniogramme*.

**DICTYOSPERMA** (Greek, *netted seed*). *Palmaceæ*. *Areca*-like palms, comprising several species of desirable pinnate house and table palms that are becoming deservedly well known.

Slender spineless palms, with a ringed trunk: lvs. equally pinnatisect; segms. linear-lanceolate, acuminate or bifid, the apical ones confluent; margins thickened, recurved at the base; midrib and nerves prominent, sparsely clothed with persistent scales beneath, or naked; rachis and petiole slender, scaly, 3-sided, furrowed, sheath elongated, entire: spadix on a short glabrous or tomentose peduncle, the branches erect or spreading and flexuose, the lower ones with membranaceous bracts at the base; spathes 2, complete, dorsally compressed, papery, the lower one 2-crested; fl.-bearing areas much depressed; bracts and bractlets scaly; pistillate fls. rather large, white or yellowish: fr. scaly, small, olive-shaped or subglobose.—There are 6 or 8 species all from Trop. Asia but only the following seem to be known in the trade. For cult., see *Areca* from which *Dictyosperma* differs only in having a 1-celled and 1-seeded fr.

**álba**, Wendl. & Drude (*Arèca álba*, Bory. *Ptychosperma álba*, Scheff.). Distinguished by the whitish petioles and the whitish green veins of the lvs.: caudex about 30 ft. high, 8-9 in. diam., dilated at the base; lvs. 8-12 ft. long; petiole 6-18 in. long, grooved down the face; segms. 2½-3 ft. long, 2-3 in. wide, 7-nerved; veins and margins green or reddish: branches of the spadix 6-18 in. long, erect or slightly reflexed, zigzag when young.—By far the best of the genus and rather widely sold as *Areca* as is also *D. rubra*.

**aúrea**, Wendl. & Drude (*Arèca aúrea*, Hort.) Distinguished by the yellow or orange petioles and veins of young plants: caudex about 30 ft. high, smaller and more slender than the preceding: lvs. 4-8 ft. long; petiole 8 in. long; segms. 1½-2 ft. long, 1 in. wide; secondary veins scarcely visible: branches of the spadix rigidly erect, 9-11 in. long.

**furfurácea**, Wendl. & Drude (*Arèca furfurácea*, Hort.). Like *D. rubra*, but the petiole and lf.-sheath of the young plant tomentose.

**rúbra**, Wendl. & Drude (*Arèca rúbra*, Hort.). Resembling *D. álba*, but the lvs. of the young plants

darker green, the primary veins and margins dark red, the redness disappearing very much in adult plants: branches of the spadix longer and more reflexed. —Young plants of this may be used for table decorations as the plant grows quickly and is attractive in juvenile condition.

JARED G. SMITH.

N. TAYLOR.†

**DICÝRTA** (*twice curved*, referring to structure of fls.). *Gesneriaceæ*. Very closely related to *Achimenes* with which some authors unite it, differing in the smaller fls., and diverging anther-cells. Low-growing slender villous herbs with creeping roots: lvs. opposite, membranaceous: fls. axillary, small, white or pale lilac, sometimes spotted; corolla-tube declinate, the limb oblique with 5 nearly equal spreading lobes; stamens affixed in the base of the corolla-tube, included, the anther-cells distinct. Two species occur in Guatemala. **D. cándida**, Hanst. & Klotzsch (*Achimenes cándida*, Lindl. *Diastema gráclle*, Regel). To 1½ ft.: lvs. ovate to ovate-lanceolate, acuminate, serrate, short-petioled: fl. on a bracted pedicel that much exceeds the petiole, white, tubular-campanulate, the lowest lobe projecting. Summer. The other species is *D. Warscewicziana*, Regel (*A. misera*, Lindl.), apparently not in cult.: fls. smaller.

L. H. B.

**DIDÍSCUS**: *Trachymene*.

**DIDYMOCÁRPUS** (*twin fruit*). *Gesneriaceæ*. Attractive warmhouse herbs, with few showy flowers.

A polymorphous genus, distributed in E. India, Malaya, China, and Trop. Afr., differently named and defined by different authors. Roettlera is an older name, and has been used recently, but it is discarded by the "nomina conservanda" list of the Vienna code. The genus includes *Chirita* and *Trachystigma* according to Fritsch, and it then numbers more than 100 species. Bentham & Hooker omit *Chirita*, which differs in its 2-parted stigma, always 2 stamens, and other characters; in this work it is kept distinct. *Didymocarpus* comprises plants that are caulescent or nearly acaulescent, sometimes woody, of various habit: lvs. radical and cauline, those on the st. opposite or alternate, crenate, more or less wrinkled and hairy: fls. violet, blue, white or even yellow, on few-fl. scapes or axillary peduncles; corolla with an elongated tube which is widened at the throat or ventricose, the limb spreading and somewhat 2-lobed; stamens 2 or rarely 4, the anthers connivent or coherent and cells divergent; style long or short, the stigma little dilated and entire or nearly so.—The species require the treatment given the warmhouse gesneriaceous plants; usually difficult to grow, or are soon lost because seeds may not be produced. Several species are mentioned in horticultural literature; but the following are more recently intro. and are likely to be cult. or perhaps in the trade. They are low herbs with few lvs., resembling *Streptocarpus*. Many new species have recently been added to this interesting genus, and a number of them may be expected to appear in cult.

**cyaneus**, Ridley. Stemless: lvs. in a rosette, ovate, elliptic or obovate, ascending, somewhat obtuse, to 6 in. long, crenate-serrate, soft pubescent, petioled: fls. deep blue, trumpet-shaped, about 1½ in. long, with rounded spreading lobes, 4 or 5 on a scape. Malaya. B.M. 8204.—Blooms in autumn; should have warm treatment, such as is given *Streptocarpus*.

**Veitchiana**, W. W. Smith. Eight in. or less: lvs. 2-4 pairs, ovate, somewhat cordate at base, serrate, 4 in. or less long, stalked: fls. lilac with longitudinal lines, tubular, nearly 1¼ in. long, in few-fl. axillary cymes. China.

L. H. B.

**DIDYMOCHLÆNA** (Greek, *twin cloak*; alluding to the indusium). *Polypodiaceæ*. Greenhouse ferns of rather coarse foliage.

Indusium elliptical, emarginate at the base, attached along a central vein, free all around the margin.—One or 2 species. Large coarse ferns somewhat resembling the shield ferns, *Dryopteris*, in habit and gross appearance.

*D. lunulata* is a very distinct fern. It looks like a tree maidenhair, but the stems are thick and fleshy and the leaves are fleshier than any *Adiantum*. In cultivation the trunk is only a few inches high, but the fronds are 4 to 6 feet long and densely covered with long, brown, chafy scales and has a metallic luster. This is a warmhouse fern, and may be used for subtropical bedding. It has a bad trick of dropping its pinnules if allowed to get too dry at the root, but soon rallies under liberal treatment.

**lunulata**, Desv. (*D. trunculata*, Hort.). Fig. 1260. Lvs. clustered from an erect rigid st., bipinnate, 3-6 ft. long; pinnules almost quadrangular, ¾-1 in. broad, entire or slightly sinuate, each bearing 2-6 sori. Cuba to Brazil; the same or an allied species in Madagascar and Malaya. —*D. lunulata* is a very attractive fern while in a small state, but its deciduous articulated pinnules are a drawback as a commercial species, rendering it of little value for house decoration.

L. M. UNDERWOOD and  
W. H. TAPLIN.

#### DIDYMOPLÉXIS

(*double or twin plaits*).

*Orchidaceæ*. One saprophytic orchid with leafless sts. *D. pallens*, Griff., has been cult. abroad but is probably not in the trade: root branching and tuberous, bearing a st. 4-6 in. high with loose sheaths: racemes terminal, with 4-8 small brownish or dull yellow-white fls.; perianth ½ in. diam.; lip stipitate, transversely oblong, with 3 nerves and a papillose disk; pedicels becoming greatly elongated after fertilization. E. India.—The genus *Didymoplexis* comprises 2 or 3 species (*Leucorchis* is a more recent name), in India, Malaya and the Pacific Isls., characterized by simple flexuous scapes, dorsal sepals and petals connate into a 3-parted upper lip, the lateral connate into an entire or 2-parted lower lip, the regular lip inserted on the foot of the column, very short and broad, entire; caps. becoming very long-pedicelled. Apparently of little horticultural interest.

**DIDYMOSPÉRMA** (Greek, *double-seeded*). *Palmaçæ*, tribe *Arècæ*. Low or almost stemless pinnate oriental palms.

Leaves terminal, unequally pinnatisect, silvery-scaly below; segms. opposite, alternate, solitary, or the lower ones in groups, cuneate at the base, obovate-oblong or oblanceolate, sinuate-lobed and erose, the terminal one cuneate; margins recurved at the base; midnerve distinct, nerves flabellate; sheath short, fibrous: spadices with a short, thick peduncle and thick branches; spathes numerous, sheathing the spadix; fls. rather large; calyx 3-ld., corolla with 3 stiff petals;

1260. *Didymochlæna lunulata*.  
(×¼)

ovary 2-3-celled: fr. ovoid or oblong, 2-3-, rarely 1-, seeded.

*Didymosperma* is a genus of East Indian palms of moderate growth, containing possibly eight species, most of which are stemless or else forming but a short trunk, the pinnate leaves rising from a mass of coarse brownish fibers that surround the base of the plant. The leaflets are of irregular shape, bearing some resemblance to those of *Caryota*, and the plants frequently throw up suckers from the base. The members of this genus are not very common in cultivation. The species that is most frequently seen is the plant known to the trade as *D. caryotoides*, an attractive warmhouse palm that has also appeared under the synonym *Harina caryotoides*, and has lately been referred to *Wallichia*, which see. While young, at least, the *didymospermas* enjoy a warm house and moist atmosphere with shading from full sunshine, though one species, *D. oblongifolia* (or *Wallichia*), is frequently found in Sikkim at an elevation of 3,000 feet above the sea. Propagated usually by seeds; occasionally by suckers, which are kept rather close for a time after their removal from the parent plant. See G.C. II. 24:362 for description of garden forms.

**porphyrocárpón**, Wendl. & Drude (*Wallichia porphyrocárpa*, Mart.). Sts. reedy, 3-6 ft.: lvs. 5-8 ft. long; lflets. 9-15, about 6 in. long, distant, narrowly oblong, long-cuneate, blunt, or sinuately 2-3-lobed, truncate, denticulate, glaucous beneath. Java.

**nànum**, Hook. A dwarf robust palm, 2-3 ft., covered with rusty pubescence: lvs. 1-2 ft. long, glabrous above, glaucous beneath; lflets. 1-3 pairs with an odd terminal one, 7-10 in. long, 3-5 in. broad, wedge-shaped, sharply toothed. Assam. B.M. 6836.—One of the smallest of all palms.

*D. Hookeriàna*, Becc. Resembles a *Caryota*, about 3 ft. high. Malay Penins. Plant scarcely known in cult. in Amer. but perhaps cult. in Eu.

JARED G. SMITH.

N. TAYLOR.†

**DIEFFENBÁCHIA** (J. F. Dieffenbach, a German botanist, 1794-1847) *Araceæ*. Popular hothouse plants, grown for their handsome and striking foliage.

Low, shrubby perennials: sts. rather thick, inclined or creeping at the base, then erect, with a leafy top:

1261. *Dieffenbachia picta* var. *Bausei*.

petioles half-cylindrical, sheathed to above the middle, long, cylindrical at the apex; blade oblong, with a thick midrib at the base; veins very numerous, the first and second parallel, ascending, curving upward at their ends; peduncle shorter than the lvs. Differs from *Aglaonema* in floral characters. Cent. and S. Amer.—

Perhaps a dozen species. Engler (in Engler & Prantl, 1889) recognizes many species, with many varieties.

For *dieffenbachias*, similar rooting material to that mentioned for *anthuriums*, combined with a high and moist atmosphere, will produce a very healthy and luxuriant growth of foliage, especially after the plants have made their first few leaves in ordinary light potting soil. Unless it be the very large-leaved kinds, like *D. triumphans*, *D. nobilis* and *D. Baummannii*, three or four plants may be placed together in large pots, keeping the balls near the surface in potting. *D. Jenmanii*, *D. Shuttleworthiana*, *D. Leopoldii* and *D. eburnea* are all well suited for massing together in large pots. When above a certain height, varying in different species, the plants come to have fewer leaves, and those that remain are small; they should then be topped, retaining a considerable piece of the stem, and placed in the sand-bed, where they will throw out thick roots in a week or two. The remaining part of the stems should then be cut up into pieces 2 or 3 inches long, dried for a day or so, and then put into boxes of sand, when, if kept warm and only slightly moist, every piece will send out a shoot, and from the base of this shoot roots will be produced. These can be potted up as soon as roots have formed. (G. W. Oliver.)

**picta**, Schott (*D. brasiliensis*, Veitch. *D. Shuttleworthiana*, Regel). Blade oblong, or oblong-elliptical, or oblong-lanceolate,  $2\frac{1}{2}$ -4 times longer than wide, rounded or acute at the base, gradually narrowing to the long acuminate-cuspidate apex, green, with numerous irregular oblong or linear spots between the veins; veins 15-20 on each side, ascending. L.B.C. 7:608 (as, *Caladium maculatum*). J.H. III. 46:165

Var. **Bausei**, Engler (*D. Bausei*, Regel). Fig. 1261. Blade nearly or completely yellowish green, with obscurely green-spotted margins and scattered white spots. I.H. 26:338.

Var. **Shuttleworthiana**, Engler (*D. Shuttleworthiana*, Bull.). Blade pale green along the midrib.

**Seguine**, Schott. Lvs. green, with white, more or less confluent stripes and spots, oblong or ovate-oblong, rounded or slightly cordate or subacute at the base, narrowed toward the apex, short cuspidate; primary veins 9-15, the lower spreading, the upper remote and ascending. Lowe 14 (as var. *maculata*). W. Indies.—Called "dumb plant" because those who chew it sometimes lose the power of speech for several days.

Var. **Baraquiniana**, Engler (*D. Baraquiniana*, Versch. & Lem. *D. gigantea*, Versch. *D. Verschaffeltii*, Hort. Petioles and also midribs almost entirely white; blade with scattered white spots. I.H. 11:387; 13:470, 471. G. 2:238.

Var. **nobilis**, Engler (*D. nobile*, Hort.). Fig. 1262. Blade elliptical, acute, dull green with dirty green spots. Brazil.

Var. **liturata**, Engler (*D. liturata*, Schott. *D. variegata*, Hort. *D. Leopoldii*, Bull. *D. Wallisii*, Lind.). Blade dark green, with a rather broad, yellowish green, ragged-margined stripe along the midrib: spathe glaucous-green. Province Para, Brazil. I.H. 17:11. S.H. 1, p. 455. G.Z. 25, p. 250.

Var. **irrorata**, Engler (*D. irrorata*, Schott. *D. Baumannii*, Hort.). Lvs. large and bright green, blotched and sprinkled with white. Brazil.

The above are the recognized two type species. The following are or have been in the American trade. Probably some or all of them belong to the foregoing species:

**Chélsonii**, Bull. Lvs. deep, satiny green, the middle gray-feathered, and the blade also blotched yellow-green. Colombia.

**eburnea**, Hort. Compact: lvs. light green, freely spotted with white, the sts. reddish and white-ribbed. Brazil.

**Fournièri**, Hort. Vigorous: lvs. large, leathery, with spots and blotches of white on a blackish green background. Colombia.

**illústris**, Hort. See *D. latimaculata*.

**imperator**, Hort. Lvs. 16-18 in. long, 5-6 in. wide, olive-green, fantastically blotched, marbled and spotted with pale yellow and white. Colombia.

1262. *Dieffenbachia Seguine* var. *nobilis*.

**insignis**, Hort. Lvs. dark green, with irregular, angular blotches of pale yellowish green, 6 or more in. wide, ovate and short-acuminate in form and with pale green petiole. Colombia.

**latimaculata**, Lind. & André (*D. illústris*, Hort.). Lvs. glaucous-green, profusely white-barred and white-spotted and blotched with yellow-green, the petioles also glaucous. Brazil. I.H. 23:234.

**Jénmanii**, Veitch. Lvs. rich, bright, glossy green, relieved by a milk-white band at every lateral nerve, and by a few white spots interspersed between the bands. Guiana. G.Z. 28, p. 218.

**magnifica**, Lind. & Rod. Lvs. ovate-acuminate, large, dark green, attractively blotched and spotted with white along the veins; sts. and petioles also variegated. Venezuela. I.H. 30:482. S.H. 2, p. 383. G. 13:643.

**marmorea**, Hort. See *D. Parlatoresi*.

**meleagrís**, L. Lind. & Rod. Lvs. with the long petioles green, marked with ivory-white, the blades dark green above, paler beneath, marked on both sides with a few white spots. Ecuador. I.H. 39:559.

**memòria-Còrsii**. A hybrid raised in the garden of the late Marquis Corsi.

**Parlatòrei**, Lind. & André, var. **marmorea**, André (*D. memòria*, *D. mormòra* and *D. Còrsii*, Hort.). Lvs. long-oblong, acuminate, the midrib white and the blades blotched white, the green deep and lustrous. Colombia. I.H. 24:291.—Engler refers this plant to the genus *Philodendron*.

**Regina**, Bull. Lvs. oblong-elliptical, rounded at base, short-acuminate at apex, greenish white, profusely mottled and blotched with alternate light and green tints. S. Amer. G.Z. 28, p. 26.—The vari-colored and margined lvs. are very attractive.

**Réx**, Hort. Compact: lvs. oblong-lanceolate, the two sides not equal, deep green, but the white angular blotches and midrib occupying more space than the green. S. Amer. G.Z. 28, p. 97.

**Sándæra**, Hort. Lvs. very broad-oval, green, mottled with cream-color.

**spléndens**, Bull. St. faintly mottled with dark and light green: lvs. have a thick, ivory-white midrib, and the ground-color is of a deep, rich, velvety bottle-green, with a resplendent, lustrous surface, freely marked with whitish striate blotches. Colombia. G.Z. 25, p. 193.

**tríumphans**, Bull. Lvs. dark green, ovate-lanceolate and acuminate, 1 ft. long, irregularly marked with angular yellowish blotches. Colombia. JARED G. SMITH

GEORGE V. NASH. †

**DIELÝTRA**: *Dicentra*.

**DIERÀMA** (a *funnel*, alluding to shape of fls.). *Iridacæ*. S. African cormous plants, related to *Sparaxis* and *Ixia*. Fls. large, white to purple and red, in panicle spikes: lvs. long, linear, rigid: perianth short-tubed, expanded at throat, with oblong nearly equal segms.; stamens 3, inserted on the perianth throat; ovary 3-celled, oblong, with many ovules, the style exerted: fr. a 3-valved caps. There are 2 or 3 species, of which *D. pulcherrima*, Baker, was intro. into S. Calif. many years ago: scape 2-6 ft., with remote branches: lvs. narrow-sword-shaped and with a very slender point: fls. 1½ in. long, pendulous, blood-red-purple, bell-shaped. B.M. 5555 (as *Sparaxis pulcherrima*). Requires the treatment given *Ixia*.

**DIERVILLA** (after Diereville, a French surgeon, who took *D. Lonicera* to Europe early in the eighteenth century). *Caprifoliacæ*. WEIGELA. Ornamental deciduous shrubs, grown for their showy flowers appearing profusely in spring and early summer.

Leaves opposite, petioled or nearly sessile, serrate: fls. in 1- to several-flid. axillary cymes, often panicle at the end of the branches, yellowish white, pink or crimson, epigynous; calyx 5-toothed or 5-parted; corolla tubular or campanulate, 5-lobed, sometimes slightly 2-lipped; stamens 5; style slender with large capitate stigma; ovary inferior, elongated, 2-celled: fr. a slender, 2-valved caps. with numerous minute seeds.—About 10 species in E. Asia and N. Amer.

*Diervillas* are shrubs of spreading habit, with more or less arching branches, rather large leaves, and, especially the Asiatic species, with very showy flowers from pure white to dark crimson, appearing in spring. A very large number of hybrids between the different Asiatic species have been raised and have become great favorites in gardens on account of their profusely produced and delicately tinted flowers. The earliest to bloom are *D. præcox* and its hybrids and also *D. florida* var. *venusta*, which begin to flower in Massachusetts about the middle of May; the latest is *D. rivularis*. The American species are hardy North and prefer moist and partly shaded positions. Of the Asiatic species *D. Middendorffiana* is the hardiest, but rarely does well: it seems to grow best in humid sandy or peaty soil and in positions sheltered from strong winds; it dislikes hot and dry air; *D. florida* also is rather hardy and one of the handsomest species of the genus. The other Asiatic species require protection during the winter or sheltered positions. They thrive well in any humid garden soil. Propagation is readily effected by greenwood cuttings or hardwood cuttings; the American species usually by suckers and by seeds sown in spring.

a. Fls. yellow, slightly 2-lipped, small, about  $\frac{1}{2}$  in. long. (*Diervilla proper*).

b. Lvs. glabrous or nearly so.

1. *Lonicera*, Mill. (*D. trifida*, Moench. *D. canadensis*, Willd.). Shrub, to 3 ft.: branchlets nearly terete, glabrous: lvs. distinctly petioled, ovate-oblong, acuminate, serrate, nearly glabrous, finely ciliate,  $1\frac{1}{2}$ –4 in. long: cymes usually 3-fld.; limb nearly equal to the tube: caps. about  $\frac{1}{3}$  in. long. June, July. Newfoundland to Sask., south to Ky. and N. C. B.M. 1796.

2. *sessilifolia*, Buckl. Shrub, to 5 ft.: branchlets quadrangular: lvs. nearly sessile, ovate-lanceolate, serrate, nearly glabrous, of firmer texture, 2–6 in. long: cymes 3–7-fld., often crowded into dense, terminal panicles; limb shorter than the tube: caps. about  $\frac{1}{2}$  in.

1263. *Diervilla japonica*. ( $\times \frac{1}{3}$ )

long. June, July. N. C. and Tenn. to Ga. and Ala. G.C. III. 22:14; 42:427.—Hardy in Canada.

BB. Lvs., branchlets and infl. pubescent.

3. *rivularis*, Gatinger. Shrub, to 6 ft.: lvs. short-petioled, ovate to oblong-lanceolate, acuminate, truncate or cordate at the base, doubly serrate, pubescent on both sides,  $1\frac{1}{2}$ – $3\frac{1}{2}$  in. long: cymes few- to many-fld., crowded into terminal panicles; limb of corolla about as long as tube: caps.  $\frac{1}{4}$  in. long. July, Aug. N.C. to Tenn., Ga. and Ala. G.C. III. 38:339.

AA. Fls. showy, white, pink, or crimson, rarely yellowish.

b. Anthers not connected with each other. (*Weigela*.)

c. Calyx-lobes lanceolate, connate to or nearly to the middle; stigma 2-lobed: seeds almost wingless.

4. *florida*, Sieb. & Zucc. (*Weigela rosea*, Lindl. *W. amabilis*, Hort. *D. pauciflora*, Carr.). Shrub, to 6 ft.: branchlets with 2 hairy stripes: lvs. short-petioled or nearly sessile, elliptic or ovate-oblong to obovate, serrate, glabrous above except at the midrib, more or less pubescent or tomentose on the veins beneath, 2–4 in. long: calyx nearly glabrous, with lanceolate teeth; ovary slightly hairy; fls. 1–3, pale or deep rose,  $1\frac{1}{4}$  in. long; corolla broadly funnel-shaped, abruptly narrowed below the middle. May, June. N. China. B.M. 4396. F.S. 3:211. B.H. 1:577. Gt. 54, p. 86. R.H. 1849:381. H.F. 1854:21. V. 18:37.—This is one of the most cult. species, very free-flowering and rather hardy. Var. *alba*, Moore. Fls. white, changing to light pink. R.H. 1861:331. Var. *venusta*, Rehd.

Lvs. smaller, usually obovate,  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. long, usually nearly glabrous: fls. in dense clusters with small lvs. at the base; corolla slender, about  $1\frac{1}{2}$  in. long, rather gradually narrowed toward the base, lobes oval to oval-oblong, rosy pink. Korea, N. China.—Recently intro.; very floriferous, early and hardy.

5. *præcox*, Lemoine. Shrub, to 6 ft.: branchlets glabrous: lvs. short-petioled, elliptic or elliptic-ovate, acuminate, serrate, hairy above, soft-pubescent below, 2– $3\frac{1}{2}$  in. long: fls. clustered, 3–5, nodding; calyx with subulate lobes; ovary hairy; corolla abruptly narrowed below the middle, purplish pink or rose-carmine. Japan. May. Gt. 46:1441; 53, p. 522. R.H. 1905:314.—The earliest of all species to bloom; has given rise to a race of early-flowering hybrids as *Avalanche*, *Gracieux*, *Vestale*, *Conquerant*, *Esperance*, *Seduction*, which see under *D. hybrida*.

cc. Calyx-lobes linear, divided to the base: seeds winged: stigma capitate.

d. Plant nearly glabrous.

6. *coræensis*, DC. (*D. grandiflora*, Sieb. & Zucc. *D. amabilis*, Carr.). Shrub, 5–10 ft.: lvs. rather large, obovate or elliptic, abruptly acuminate, crenately serrate, sparingly hairy on the veins beneath and on the petioles: fls. in 1–3-fld., peduncled cymes; corolla broadly funnelform, abruptly narrowed below the middle, changing from whitish or pale pink to carmine. May, June. Japan. S.Z. 31. F.S. 8:855. H.U. 1:19.—Vigorously growing shrub, with large lvs. and fls., but less free-flowering, and the type not common in cult. Var. *arborea*, Rehd. (*W. arborea grandiflora*, Hort.). Fls. yellowish white, changing to pale rose; of vigorous growth.

DD. Plant more or less pubescent: corolla finely pubescent outside.

7. *japonica*, DC. Fig. 1263. Shrub, to 6 ft.: lvs. oblong-obovate or elliptic, acuminate-serrate, sparingly pubescent above, tomentose beneath: fls. usually in 3-fld., short-peduncled cymes, often crowded at the end of short branchlets; corolla broadly funnelform, narrowed below the middle, whitish at first, changing to carmine, slightly pubescent or nearly glabrous outside; style somewhat exserted. May, June. Japan, China. G.F. 9:405 (adapted in Fig. 1263). Gn. 21, p. 184. Var. *hortensis*, Rehd. (*D. hortensis*, Sieb. & Zucc.). Lvs. nearly glabrous above, densely grayish tomentose beneath: cymes usually rather long-peduncled; fls. usually carmine. S.Z. 29, 30. More tender and slower-growing than the type. Var. *sinica*, Rehd. Lvs. slender-petioled, soft-pubescent beneath: fls. campanulate, abruptly contracted below the middle into a narrow tube, pale pink. Cent. China. Var. *alba*, Makino (*D. hortensis* var. *alba*, Sieb. & Zucc. *D. japonica* var. *nivea*, Rehd.). Like var. *hortensis* but fls. white. G.C. II. 10:80. Gn. 22, p. 185; 34, p. 352. G. 28:392.

8. *floribunda*, Sieb. & Zucc. (*D. multiflora*, Lem.). Shrub, to 8 ft.: lvs. oblong-ovate or elliptic, acuminate, serrate, sparingly pubescent above, more densely beneath: fls. 1–3, usually sessile, mostly crowded at the end of short branchlets; corolla rather gradually narrowed toward the base, pubescent outside, brownish crimson in the bud, changing to dark or bright crimson; lobes about 5 times shorter than the tube; style exserted. May, June. Japan. S.Z. 32. I.H. 10:383.—Vigorously growing shrub, with rather small but abundant fls. Var. *grandiflora*, Rehd. (*W. arborescens*, Hort.). Fls. rather large, brownish crimson. Var. *versicolor*, Rehd. (*D. versicolor*, Sieb. & Zucc.) Fls. greenish white at first, changing to crimson. S.Z. 33.

9. *hybrida*, Hort. (Fig. 1264), may be used as a collective name for the different hybrids between *D. florida*, *D. præcox*, *D. floribunda*, *D. japonica* and *D. coræensis*, which are now more commonly cult. than the

XXXVI. A border of dianthus and digitalis.

typical species. Some of the best and most distinct are the following, arranged according to the color of the fls. The numbers in parenthesis after the name refer to the number of the species and indicate the origin or probable origin of these hybrids:

1264. *Diervilla hybrida*. ( $\times \frac{1}{2}$ )

Fls. white or nearly white: *Avalanche*, Lemoine (5 $\times$ ?). Fls. pure white; early, *Dame Blanche* (6 $\times$ 7). Fls. large, white, slightly pinkish outside, yellowish white and bluish in bud. *Gracieux*, Lemoine (5 $\times$ ?). Fls. white, yellow in throat, buds light salmon-pink; early, *Isoline*, Van Houtte (4 $\times$ ?). Fls. white or slightly pink outside, yellow in throat. *Madame Couturier*, Billiard (4 $\times$ 6). Fls. yellowish white changing to pink. *Madame Lemoine*, Billiard (4 $\times$ 6). Fls. white with delicate bluish, changing to pink. *Madame Tellier*, Billiard (4 $\times$ 6). Fls. large, white, with delicate bluish. *Vestale*, Lemoine (5 $\times$ ?). Fls. pure creamy white. *Mont-blanc*, Lemoine (4 $\times$ 7). Fls. pure white, greenish white in bud, fading to pinkish. *Pavillon Blanc*, Lemoine. (4 $\times$ 7). Similar to the preceding. *Candida* (4 $\times$ 6). Fls. pure white. R.H. 1879:130.

Fls. pink or carmine: *Abel Carrière* (4 $\times$ 7). Fls. rose-carmine, purple-carmine in bud, with yellow spot in throat. *André Thouin* (4 $\times$ 6). Fls. pink, carmine in bud. *Conquérant*, Lemoine (5 $\times$ ?). Fls. very large, rose-colored, carmine outside and in throat; early. *Conquête* (4 $\times$ 7). Fls. very large, deep pink. *Dr. Buillard* (4 $\times$ 7). Fls. carmine. *Esperance*, Lemoine (5 $\times$ ?). Fls. very large, pinkish white tinged with salmon-red, buds pale salmon; early. *Gratissima* (4 $\times$ 7). Fls. light pink. *Gravevegenii* (4 $\times$ ?). Fls. red outside, whitish within, slightly striped with yellowish red. *Gustave Mallet*, Billiard (4 $\times$ 6). Fls. light pink, bordered white. *Hendersonii* (4 $\times$ 8). Fls. light crimson. *Intermedia* (4 $\times$ 7). Fls. carmine, buds darker. *Othello* (4 $\times$ 8). Fls. carmine, darker outside. *Seduction*, Lemoine (5 $\times$ ?). Fls. vinous carmine-red, early, very floriferous. *Steltzeri*, Van Houtte (4 $\times$ 7). Fls. dark red, abundant. *Styriaca*, Klenert (4 $\times$ 8). Fls. pink, changing to pinkish carmine, very floriferous. M.D. 1912:1. *Van Houttei* (4 $\times$ 7). Fls. carmine. F.S. 14:1447. *Venosa* (4 $\times$ 6). Fls. carmine-pink, carmine in bud, orange to crimson in throat. *Verschaffeltii* (4 $\times$ 6). Fls. carmine-pink, limb bordered whitish.

Fls. crimson or dark crimson: *Congo* (6 $\times$ 8). Fls. large, purplish crimson, abundant. *Desboisii* (8 $\times$ 7). Fls. small, dark crimson. *E. André* (8 $\times$ 6). Fls. very dark, brownish purple. *Eva Rathke* (8 $\times$ 6). Fls. deep carmine-red, erect; very free-flowering. R.B. 19:126. G. 14:1350. *Hendersonii* (4 $\times$ 8). Fls. light crimson, crimson in bud. *Incrinata* (6 $\times$ 8). Fls. deep red. *Lavallei* (6 $\times$ 8). Fls. bright crimson. H.F. 1870:5. G.W. 1, p. 60 (habit). *Loweii* (8 $\times$ 4). Fls. dark purplish crimson. H.F. 1870:8. *P. Duchartre* (4 $\times$ 8). Fls. deep amaranth, very dark; free-flowering.

Lvs. variously colored: *Kosteriana variegata*. Lvs. bordered yellow; fls. pink, paler in bud, dwarf. *Looymansii aurea*. Lvs. yellow; of slow growth. R.B. 2:173. *Luteo-marginata* (Weigela anabilisfol. var. Van Houtte). Lvs. bordered yellow. F.S. 12:1189. *Nana variegata* (Weigela rosea nana fol. var. Van Houtte). Lvs. variegated with white; fls. nearly white; dwarf. *Sieboldii argenteo-marginata* (4 $\times$ 7). Lvs. bordered white; fls. rose.

BB. Anthers connected with each other. (Calyptr stigma.)

10. *Middendorffiana*, Carr. Shrub, to 3 ft.: lvs. short-petioled, ovate-oblong or oblong-lanceolate, ser-

rate, glabrous at length; fls. in 2-3-fld. axillary and terminal clusters; corolla campanulate-funnelform, yellowish white, spotted orange or purplish inside  $1\frac{1}{2}$  in. long; calyx-teeth partially connate. May, June. E. Siberia, N. China, Japan. Gt. 6:183. R.H. 1854:261. F.S. 11:1137. I.H. 4:115. G.C. III. 7:581.—Hardy, but rarely does well; it demands a cool and moist climate and a position sheltered from strong winds.

*D. splendens*, Carr. (*D. Lonicera*  $\times$  *D. sessilifolia*). Intermediate between the parents; more similar to *L. sessilifolia*, but lvs. short-petioled. Garden origin.—*D. suavis*, Komarov. Allied to *D. japonica*. Lvs. ovate-lanceolate, ciliate, otherwise glabrous, sparingly serrate, 1-2 in. long; corolla white, pink outside; style not exerted. Manchuria. Recently intro.; presumably quite hardy.—*D. Wagneri*, Kusnezov (*D. japonica*  $\times$  *D. Middendorffiana*). Lvs. ovate-oblong, glabrous except on the veins below; fls. axillary on short branchlets; sepals lanceolate, distinct or partly connate, pink, tinged yellowish. Garden origin. Gt. 48:1461.—Doubtful whether still in cult.

ALFRED REHDER.

DIÈTES: *Moræa*.

**DIGITALIS** (Latin, *digitalis*, finger of a glove, referring to the shape of the flowers). *Scrophulariaceæ*, FOX-GLOVE. A fine genus, numbering several species, and some hybrids, of hardy or half-hardy herbaceous plants, well known for their long racemes of inflated flowers, which suggest spires or towers of bells. Plate XXXVI.

Upright herbs, sometimes woody at the base, glabrous or tomentose or woolly, mostly simple: lvs. alternate or scattered or crowded, entire or dentate: fls. showy, in a long terminal raceme or spike which is usually 1-sided, purple, ochroleucous or white; corolla declined, more or less campanulate, often constricted above the ovary, the limb erect-spreading and somewhat 2-lipped, spotted and bearded at the throat; stamens 4, didynamous, usually included; style slender, 2-lobed: fr. an ovate dehiscent caps.—About 25 species, Eu. and W. and Cent. Asia.

The foxgloves are old-fashioned and dignified, clean of growth and wholesome company in the choicest garden. The strong vertical lines of their flower-stalks, rising from rich and luxuriant masses of cauline leaves, give always an appearance of strength to the rambling outlines of the usual herbaceous border. For a week or two the foxgloves usually dominate the whole border. The usual species in cultivation is *D. purpurea*, which is one of the commonest English wild flowers. The name "foxglove" is so inappropriate that much ingenious speculation has been aroused, but its origin is lost in antiquity. The word "fox" is often said to be a corruption of "folk," meaning the "little folk" or fairies. Unfortunately, etymologists discredit this pretty suggestion. In the drugstores, several preparations of *D. purpurea* are sold. They are diuretic, sedative, narcotic. For medicinal purposes, the leaves of the second year's

1265. The juvenile or foliage stage of *Digitalis purpurea*, used as an edging. Year preceding the bloom.

growth are used.—Foxgloves are of the easiest culture. The common species and hybrids can be grown as biennials from seed. The perennial species are propagated by seeds or by division. The common *D. purpurea* is best treated as a biennial, although it may sometimes persist longer. Seeds sown one spring (or fall) will give good blooming plants the following season. The large root-leaves before the flower-stems appear are decorative (Fig. 1265).

*A. Middle lobe of the lower lip longer than the others.*

*ferruginea*, Linn. (*D. aurea*, Lindl.). Biennial or perennial, 4–6 ft. high: sts. densely leafy: lvs. glabrous or ciliate: racemes long, dense; fls. rusty red, reticulate-marked, downy outside; lower lip of corolla ovate, entire, bearded, July. S. Eu. B.M. 1828.

*lanata*, Ehrh. Perennial, or biennial, 2–3 ft. lvs. oblong or lanceolate, ciliate: fls. rather small, 1–1½ in. long, grayish or creamy yellow, sometimes whitish or purplish, downy, in a dense, many-fl. raceme, with bracts shorter than the fls. July, Aug. Danube River and Greece. B.M. 1159 (poor fig.).—A fine species.

*sibirica*, Lindl. Has the habit of *D. ambigua*, with fls. like those of *D. lanata*: lvs. downy, ovate-lanceolate, serrate or the upper entire: fls. ventricose, villose, yellowish; calyx-segms. linear, villose. Siberia. —This is a rare trade name, and it is doubtful whether this little known plant is really in cult.

*Thápsii*, Linn. Plant much like *D. purpurea*: perennial, 2–4 ft. high: lvs. ovate-lanceolate or oblong, rugose, decurrent: fls. purple, throat paler, marked with red dots in a lax raceme; calyx-segms. ovate or oblong. June–Sept. Spain. B.M. 2194 (as *D. tomentosa*).

*AA. Middle lobe of the lower lip shorter or hardly longer than the others.*

*ambigua*, Murr. (*D. grandiflora*, Lam. *D. ochroleuca*, Jacq.). Perennial or biennial, 2–3 ft. high: lvs.

ovate-lanceolate, toothed, sessile or clasping, downy below: fls. large, 2 in. long, yellowish, marked with brown; lower bracts about as long as the fls. Eu., W. Asia. B.R. 64.

*purpurea*, Linn. (*D. tomentosa*, Link & Hoffm.). COMMON FOXGLOVE. Fig. 1266. The species most commonly cult.: mostly biennial, but sometimes perennial: height 2–4 ft.: lvs. rugose, somewhat downy, the radical ones long-stalked and ovate to ovate-lanceolate, the st.-lvs. short-stalked and becoming small toward the top of the st.: fls. large, 2 in. long,

ranging from purple and more or less spotted, rather obscurely lobed. On dry hills and roadsides, Great Britain, W. and Cent. Eu., to Scandinavia, running into white and modified forms in cult.; sometimes escaped in this country. Gn. 34:488. Var. *gloxiniæflora*, Hort. (*D. gloxinoides*, Carr. *D. gloxinæflora*, Hort.). Of more robust habit, longer racemes, larger fls., which open wider, nearly always strongly spotted. Var. *alba*, Hort. Fls. white. Var. *monströsa*, Hort., is a double peloric form. P.G. 4:151. *D. maculata superba* is a trade name for highly improved spotted forms. Var. *campanulata*, Hort., is a monstrous form with the upper fls. united into a bell-shaped large bloom.

*D. Buxbaumii* is offered as a yellow-fl. species.—*D. dubia*, Rodr. Perennial, woolly: fls. slender, hanging, purplish, spotted inside. Balearic Isls. G. 30:309.—*D. laciniosa*, Lindl. Perennial, woody, 2 ft. high: lvs. lanceolate, jagged: fls. yellow, downy, with ovate, bearded segms.; bracts much shorter than the pedicels. Spain. B.R. 1201.—*D. levigata*, Walst. & Kit. Perennial, 2–3 ft. high: lvs. linear-lanceolate, radical ones obovate-lanceolate: fls. scattered, glabrous, yellow. Danube and Greece.—*D. lutea*, Linn. Perennial, glabrous: lvs. oblong or lanceolate, denticulate: raceme many-fl., secund; corolla yellow to white, glabrous; calyx-segms. lanceolate, acute. Eu. B.R. 251.—*D. maritima*, Boiss. Lvs. radical, very downy, ovate-oblong: fls. rose; corolla bearded. Spain.—*D. purpurascens*, Roth. Biennial: fls. yellow or sometimes purplish, pale inside, spotted at the mouth; lower lobe of corolla short. Eu.—*D. purpureo-ambigua* is a hybrid of *D. purpurea* var. *gloxiniæflora* and *D. ambigua*.

F. A. WAUGH.  
L. H. B.†

*DILIVARIA: Acanthus.*

*DILL* (*Anethum graveolens*, Linn.), an annual or biennial plant of the *Umbelliferae*, the seeds of which are used as a seasoning, as are seeds of caraway and coriander. It is of the easiest cult. from seeds. It should have a warm position. The plant grows 2–3 ft. high: the lvs. are cut into thread-like divisions: the st. is very smooth: the fls. are small and yellowish, the little petals falling early. It is a hardy plant. The foliage is sometimes used in flavoring, and medicinal preparations are made from the plant. The seeds are very flat and bitter-flavored. Native of S. E. Eu.

*DILLËNIA* (named by Linnæus for J. J. Dillenius, 1684–1747, botanist and professor at Oxford, author of important botanical works). *Dilleniaceæ*. Tall tropical trees from Asia, Indian Archipelago, Philippines, and Australia.

Leaves large, with pronounced pinnate parallel venation: fls. showy, white or yellow, lateral, solitary or clustered; sepals and petals 5, spreading; stamens many, free or somewhat united at base, the anthers linear, opening by 2 slits, the interior ones erect and introrse and the exterior ones recurved and extrorse: carpels 5–20, many-ovuled, in fr. becoming a fleshy body inclosed in the enlarging calyx.—Probably 40 species; allied to the *Magnolia* family. *D. indica* is said to be the showiest of the whole family, being attractive in foliage, fl. and fr. Dillénias may be grown in light sandy loam. Prop. readily by seeds, but with difficulty from cuttings.

*indica*, Linn. (*D. speciosa*, Thunb.). Trunk stout, not high: branches numerous, spreading, then ascending: lvs. confined to the ends of branches, on short, broad, channelled sheathing petioles, the blade 6–12 in. long, oblong, or oblong-lanceolate, acuminate, narrowed at the base, strongly serrate: sepals 5, thick, fleshy, enlarging and inclosing the fr.; petals obovate, white, large, making a fl. fully 9 in. across; stamens very numerous, forming a large yellow globe crowned by the white, slender, spreading rays of the stigma: fr. edible, acid, the size of an apple, many-celled and many-ovuled. Trop. Asia. Intro. in Fla. and S. Calif. B.M. 5016 (B.M. 449=*Hibbertia volubilis*). H.F. 1867 p. 119.

WILHELM MILLER.

*DIMORPHANTHUS: Aralia.*

1266. *Digitalis purpurea*.  
(× ½)

**DIMORPHOTHECA** (Greek, *two-formed achenes*). *Compositæ*. CAPE MARIGOLD. Annual and perennial herbs or sub-shrubs, some of which are excellent flower-garden plants.

Leaves alternate or radical, entire, toothed, or incised, often narrow: heads solitary, long-peduncled; disk-fls. yellow or brown or purple, the rays yellow, purple, or white with purple beneath. 'The genus is closely allied to *Calendula* but has straight instead of incurved frs. The fls. usually close up, like those of *Gazania*, unless they have sunlight; their backs have as great a variety of coloring as their faces.—About 20 species in S. Afr.

The flowers are often 3 inches across, and their long, slender rays (20 or more) give a distinct and charming effect. A dozen kinds are grown abroad, representing a wide range of colors and foliage. They are wintered in coolhouses and flowered in spring or else transplanted to the open, where they flower freely during summer. The shrubby kind, *D. Ecklonis*, has been grown as a summer bedding plant, flowering from July to frost, and as a coolhouse plant, making a much-branched subject 3 feet high, and flowering freely all spring.

*annua*, Less. (*Caléndula pluviâlis*, Linn.). Erect or diffuse, simple or branched annual, rough with jointed and gland-tipped hairs (seen with a small lens): lvs. narrowly oblong or obovate-oblong, tapering to the base, with a few distant teeth, pilose, the uppermost smaller and narrower: peduncles terminal, nodding in fr.; fls. white above, purple or discolored beneath. J.H. III. 57:501. Var. *ligulôsa*, Voss (*Caléndula Pöngel*, Hort.), is a double form (the heads full of rays) with heads white on upper side and yellow or violet beneath.

*sinuata*, DC. Annual, branched from the base, nearly glabrous: lvs. oblong, obtuse, sinuate, narrowed at base: involucre-scales lanceolate-acuminate, quite glabrous, longer than disk: achenes of ray trigonous, everywhere tubercled; of disk flat with thickened rim; rays orange.—Grows 12–15 in. high. Fls. shading to blue in center.

*aurantiaca*, DC. Perennial, the st. natively more or less shrubby, erect, glabrous, with rod-like branches: lvs. linear-oblong or spatulate, thickish, obtuse, entire: fl.-heads large, rays orange-yellow; involucre-scales linear-acuminate, exceeding the disk, with a central line of hairs and paler margins. This brief botanical description does not in all ways fit the plant now in common cult. as *D. aurantiaca*, which is treated as a half-hardy annual, and which is apparently more or less modified by cult.; it is a very showy plant (Fig. 1267), 12–16 in. high, from a short-decumbent base, with notched acute lvs., and terminal heads 2–2½ in. across, and with curving rays of a rich glossy apricot-orange and a disk of brown-black; it is one of the best flower-garden subjects of recent years, the fls. opening in the sun and making a brilliant display in summer and till frost; of simple culture from seeds. Although long described in horticultural literature, it appears not to have come really into cult. until within the past few years, having been offered in Eu. in the fall of 1908. Recent forms under the name of *D. aurantiaca hybrida* (hybrids with *D. annua*), intro. in 1912, range in color from white and bluish-white to red, yellow, orange and salmon. B.M. 408 (as *Caléndula Tragus*). G.C. III. 38:127. G. 31:205. J.H. III. 57:37. F.E. 31:308. Winter-flowering in S. Calif.

*Ecklonis*, DC. Shrubby at base, robust and erect, branching at top, 2 ft. or more: lvs. crowded, linear-lanceolate or lanceolate, entire or somewhat denticulate, acute: fl.-heads terminal, the rays 1½ in. long, white above and purplish beneath; involucre-scales long-acuminate. B.M. 7535. Gn. 75, p. 444. G. 24: 424; 25:565.—Not hardy north of Washington. It is grown as a summer bedding plant in England.

*D. Bárberia*, Haw. Perennial: fls. purple above, paler beneath; disk all purple, with corollas of 2 forms. B.M. 5337. H.F. II. 5:78. Var. *rosea*, Hort., has rose-colored fls.—*D. chrysanthemifolia*, DC. Lvs. cut like a chrysanthemum: fls. yellow, reverse reddish. B.M. 2218.—*D. cuneata*, DC. Lvs. strongly cut: fls. scarlet-orange. B.M. 1343.—*D. nudicaulis* var. *grammifolia*, Harv. & Sond. Fls. white, with a purple ring at the base, and orange-brown on the back, the disk purple. B.M. 5252.—*D. Tragus*, DC. Perennial: lvs. narrower than in *D. Ecklonis*, linear: fls. white, veined purple, the rays narrower at the base, reverse orange purplish, the disk purplish. B.M. 1981 (as *Calendula*). L. H. B. †

**DIOCLÆA** (after Diocles of Carystos, said to be second only to Hippocrates among the ancients for his knowledge of plants). *Leguminosæ*. Tender shrubby twiners, with delicate trifoliate leaves and blue, violet, scarlet or white flowers, sometimes nearly an inch long, and borne in clusters which have been roughly compared to *Wistaria*.

Flowers papilionaceous; calyx bell-shaped, 4-cut, 2 lobes shorter and narrower; standard orbicular or ovate, reflexed, auricled or appendaged at base; wings obovate or oblong, free; keel incurved, beaked or obtuse; ovary nearly sessile: pod wide, the upper suture thickened or 2-winged.—Perhaps 20 species in tropical regions, chiefly in the western hemisphere. What is said to be the following species is cult. in S. Calif., where it has a moderate growth, shining foliage, and clusters of 10 or more large fls. of a splendid scarlet (to be considered with reference to *Camptosema*).

*glycinoides*, Hort. Fls. 1 in. long, bright scarlet, in racemes, somewhat like *Wistaria*: will stand some cold. Prop. by seeds, cuttings, or suckers, freely produced on grown-up plants. Rio de la Plata.—Imperfectly understood botanically; said to be the same as *Camptosema rubicundum*, Hook. & Arn.

L. H. B. †

DION: *Dioon*.

**DIONÆA** (Greek name for Venus). *Droseracæ*. VENUS FLY-TRAP. A remarkable monotypic genus of insectivorous plants, often grown for

1267. *Dimorphotheca aurantiaca*, one of the best of recent flower-garden acquisitions. (×½)

curiosity and in botanical collections.

Leaves 1–5 in. long, 4–8 in number, are arranged in a spreading rosette over the soil, each consisting of a flat expanded petiole, and terminal bilobed blade; midrib of the blade contractile, the margins prolonged into bristles that interlock when the halves close, while each half bears 3 jointed and highly irritable hairs arranged in triangular manner over its upper surface; abundant sessile glands, usually of a crimson color, cover this surface and render it attractive to insects; but when grown in shade the glands and therefore the lvs. are quite green: a single neat touch of a hair fails to cause closure, but when one of the hairs is touched twice, or when two adjacent hairs are touched once within a short interval apart, the halves close. Owing

to continued and repeated stimuli caused by a caught insect, or to chemical stimuli caused by its tissues, the glands exude an acid and peptonizing digestive fluid after a few hours; this starts digestive disintegration of the insect's tissues, and the dissolved products are then absorbed by the lf.-halves: the fl.-stalk lengthens in May to 8-10 in. and bears 4-10 white fls. which expand in June, and which must be cross-pollinated for seed-production. By the end of June the caps. burst, and

expose small black shining seeds. These germinate in abundance under a bell-jar on moist sandy soil that is mixed with finely chopped sphagnum moss. Each seedling, after forming 2 lanceolate cotyledons, produces thereafter tiny fly-trapping lvs. that behave like the adult ones. Plants thrive well when grown in 3-5-in. pots amid a mixture of fine silver-sand and black silt. The pots should be kept immersed for about an inch in water, should have a slight top-covering of sphagnum, and must be kept near the glass in a green-

house with southeastern exposure. Inhabits the edges of moist sandy savannah "bottom" lands, is found wild over a narrow strip of territory about 10 miles in width and 40 miles north, also to an equal distance south of Wilmington, N. C., and grows well only

when the tips of its roots reach a moist substratum, and when active transpiration proceeds. The perennial underground part is a bulbous swelling that can readily be dug and distributed from Nov. to March.

It is seldom that this wonderful little plant is seen in a good state of cultivation any length of time after removal from its native haunts. Its cultivation in a greenhouse is usually attended with more or less difficulty, owing to unsuitable conditions, such as too much dry air, shade or unfriendly soil. It delights in full sunshine, with a very humid atmosphere. When the plants can be secured and transplanted with considerable of the soil in which they grow attached to the bulb-like rootstalks, they are quite easily dealt with, and may be kept in a healthy growing state for years. I find a round hanging earthenware receptacle most useful to grow them in; the bottom is carefully drained, first with large pieces of broken pots, then smaller pieces, and the upper layer is quite fine. Some chopped fibrous peat is placed above this, when the plants are built in with live sphagnum moss used to fill the spaces between the clumps. Arranged in this way, it is hardly possible to give them too much water, and they revel in abundant supplies. If kept in the sun the leaves take on a reddish tinge, but when grown in the shade they are always green. Flowers will develop about the middle of June, but they should be nipped off as they make their appearance, for they are apt to weaken the plant.—The *dionæa* has been grown successfully in a dwelling-house by a very different method. The plants were in a wide, shallow dish, without any drainage, and simply placed, not too firmly, in loose live sphagnum moss, with a glass covering. Water was given every other day by filling the space above the plants until the dish was filled, and then it was poured off. In this way the potting material never became sour. From the luxuriant condition in which these plants remained for years, I am inclined to think this was a close imitation of the conditions

under which they thrive in a wild state. Some years ago, owing to Asa Gray's endeavor to have the Government purchase a strip of land on which this plant grows, there existed a widespread idea that it was gradually becoming extinct. There seems to be little likelihood of this calamity, however, as *Dionæa* is found abundantly in some places. (G. W. Oliver, in *Garden and Forest*, 10:237 [1897]).

*muscipula*, Ellis. Fig. 1268. St. short, subterranean, coated by the swollen bases of lvs.: lvs. 1-5 in. long in radial rosette, divided into winged petiole and bilobed lamina; infl. umbellate; fls.  $\frac{3}{4}$ -1 in.; petals white; stamens usually 15; pistil of 5 united carpels, stigmas 5 penicillate; fr. a caps. B.M. 785. F.S. 3:280. Mn. 1, p. 69.

J. M. MACFARLANE.

**DIÖON** (Greek, *two* and *egg*; each scale covers two ovules and the seeds are in pairs). *Cycadaceæ*. Handsome foliage plants suitable for warm or temperate palm houses and for planting in the open far South.

This genus is said to be the closest to the fossil forms of any living representative of the family. It has the cones and twin seeds of *Zamia* and *Encephalartos*, with the flat woolly scales of *Cycas*, but without the marginal seeds and loose infl. of the latter.—*D. edule* has a flat rigid frond which is more easily kept free from scale insects than *Cycas revoluta*, the commonest species of the family in cult. A specimen at Kew had a trunk 3-4 ft. high and 8-10 in. thick, the crown spreading 8-10 ft. and containing 50 fronds, each 4-5 ft. long and 6-9 in. wide. Specimens of *D. spinulosum* are reported with trunk 24 ft. high. Both sexes make cones frequently, the male cone being 9-12 in. long and the female 7-12 in. The seeds, which are about the size of Spanish chestnuts are eaten by the Mexicans. There are a few species in Mex. Prop. by seeds. Cult. same as *Cycas*.

*edule*, Lindl. Lvs. pilose when young, finally glabrous, 3-5 ft. long, pinnatifid, rigid, narrowly lanceolate segms., about 100 on each side, linear-lanceolate, sharp-pointed, widest at the base, rachis flat above, convex beneath: male cones cylindrical, female cones ovoid. Mex. B.M. 6184. G.C. III. 40:289. Gn. 55, p. 365. Gt. 48, p. 157. Var. *lanuginosum*, Hort., is a very woolly kind. Gt. 48, pp. 154, 155. Variable.

*spinulosum*, Dyer. Plants 6-50 ft. high, crowned by a noble rosette of spreading lvs.: lvs. 4-3 ft. long, often with 100 lfts. on each side, these bearing 5-8 spines on each margin. This is one of the tallest of all the cycads, and is excelled only by the Australian *Cycas media*. It is very unlike *D. edule*, which has a stocky trunk and straight rigid lvs. Mex. G.W. 4, p. 326; 5, p. 331. A.F. 7:461.

*D. Doheni*, Hort. Discovered in mts. of Guatemala and named for Edward L. Doheney of Los Angeles. Pacific Garden, Nov. 1912: 13.—*D. pectinatum*, Hort. Like *C. spinulosum*: foliage described as "very handsome, owing to the very numerous pinnae and their close and regular arrangement. The texture is also firm and leathery, with a sharp spiny point to each pinna." Gn. W. 24:5.—*D. Phippsii*, Rose. Trunk short, crowned with numerous stiff and ascending lvs. 3 ft. or more long; pinnae 2-4 in. long, sharp-pointed, entire on the lower margin but usually with 1, 2, or 3 spine-like teeth on the upper margin: male cones 6-8 in. long, the bracts with recurved ovate tips; female cones ovate, about 18 in. long, the bracts very woolly. S. Mex.

WILHELM MILLER.

L. H. B.†

**DIOSCOREA** (Dioscorides, Greek naturalist of the first or second century of the Christian era). *Dioscoreaceæ*. Twining herbs from tuberous or thickened rootstocks, grown as arbor vines or under glass for the foliage, and also for the edible rhizomes and aerial tubers.

Type genus of a small family (of about 9 genera) allied to Liliaceæ. It contains more than 200 widely dispersed and confused species, most of them native to tropical regions. Sts. herbaceous and twining or long-procumbent, usually from a large tuberous root,

1268. The Venus' Fly-trap—*Dionæa muscipula*.

and sometimes bearing tubers in the axils: lvs. broad, ribbed and netted-veined, petiolate, alternate or opposite, sometimes compound: fls. dioecious, small; calyx 6-parted; anthers 6; styles 3; ovary 3-loculed and calyx adherent to it: fr. a 3-winged caps.; seeds winged.—The great subterranean tubers of some species are eaten in the manner of potatoes. Some of the kinds have handsome colored foliage and are good glasshouse subjects. Numbers of species are more or less cult. in different warm countries (see, for example, Paillieux & Bois, "Le Potager d'un Curieux," and for Japanese species Georgeson, A.G. 13:80); but it is not known that many of them have appeared in the U. S. The tuber-bearing species need to be worked over thoroughly from living plants. For an inquiry into the prehistoric cult. of dioscoreas in Amer., see Gray & Trumbull, Amer. Journ. Sci. 25:250.

All the species are of very easy cultivation from seeds or tubers or cuttings. The tubers keep a long time, like potatoes.

*A. Sts. strongly winged.*

**alata**, Linn. Fig. 1269. St. 4-winged or angular: lvs. opposite, cordate-oblong, or cordate-ovate, with a deep, basal sinus, glabrous, devoid of pellucid dots, 7-nerved (sometimes 9-nerved), with the outer pair united: staminate spikes compound, special ones whorled, short, flexuose; pistillate spikes simple; fls. distant, anthers subglobose, about as long as the filament: caps. leathery, elliptical. India and the South Sea Isls.—Widely cult. in the tropics under many vernacular names. Tubers reach a length of 6–8 ft., and sometimes weigh 100 lbs.; edible. The roots continue to grow for years. Variable.

*AA. Sts. terete (cylindrical).*

*B. Lvs. plain green.*

**Batatas**, Decne. (*D. divaricata*, Auth., not Blanco). **YAM. CHINESE YAM. CHINESE POTATO. CINNAMON-VINE.** Tall climbing (10–30 ft.), the lvs. 7–9-ribbed, cordate-ovate and shining, short-petioled, bearing small clusters of cinnamon-scented white fls. in the axils: root-tubers deep in the ground, 2–3 ft. long, usually larger at the lower end. Philippines. F.S. 10:971. R.H. 1854, pp. 247, 451, 452.—This is often grown in the tropics for its edible tubers, which, however, are difficult to dig. In this country the word yam is commonly applied to a tribe of sweet potatoes (see *Sweet Potato*). The yam is hardy. The root will remain in the ground over winter in New York, and send up handsome tall twining shoots in the spring. The plant bears little tubers in the lf.-axils, and these are usually planted to produce the cinnamon vine; but it is not until the second year that plants grown from these tubercles pro-

1269. *Dioscorea alata*, showing foliage ( $\times \frac{1}{3}$ ) and a small tuber.

duce the large or full-grown yams. A form with short and potato-like tubers is *D. Decaisneana*, Carr. (R.H. 1865:110).—A vine widely cult. since 1910 under the name "air potato" or "giant yam vine" has large potato-shaped bitter tubers. Its identity is in doubt. It is not *D. divaricata*, under which name it was intro. from Hawaii, nor *D. bulbifera*, which has angular and edible aerial tubers. In order to distin-

1270. Air potato.—Aerial tuber of *Dioscorea bulbifera*. ( $\times \frac{1}{4}$ )

guish it from the latter, it has recently been called the "Hawaiian bitter yam." The yampi is apparently a form of *D. alata*. This and other forms of this species are grown in Fla. and La., for the excellent edible tubers, which compare favorably with the potato.

**bulbifera**, Linn. **AIR POTATO.** Fig. 1270. Tall-climbing: lvs. alternate, cordate-ovate and cuspidate, 7–9-nerved, the stalks longer than the blade: fls. in long, lax, drooping, axillary racemes. Trop. Asia. G.C. III. 52:313.—Somewhat cult. S. as an oddity and for the very large angular axillary tubers (which vary greatly in size and shape). These tubers sometimes weigh several pounds. They are palatable and potato-like in flavor. The root-tubers are usually small or even none.

*BB. Lvs. variously marked and colored, at least beneath (greenhouse "foliage plants").*

**discolor**, Hort. Lvs. large, cordate-ovate, cuspidate, with several shades of green, white-banded along the midrib and purplish beneath: fls. greenish and inconspicuous: root tuberous. S. Amer. Lowe 54. F.W. 1877:353.—Useful for the conservatory. Suggestive of *Cissus discolor*.

**multicolor**, Lind. & André. Probably only a form of the last: lvs. variously marked and blotched and veined with silvery white, red, green and salmon. S. Amer. I.H. 18:53.—Very decorative glasshouse plant of several well-marked forms (some of them under Latin names).

*D. villosa*, Linn., a native dioscorea, is offered. Bartlett has recently worked over the species native to the U. S. (Bull. 189, Bur. Pl. Ind., U. S. Dept. of Agric., 1910) and has recognized 5 species in the material formerly passing as *D. villosa*; and the name villosa itself he finds to be untenable because of the confusion attending it (a similar case lies with *D. sativa*, Linn., a name applied to oriental species). The 5 species are as follows: *D. quaternata*, Gmel. Rhizomes stout,  $\frac{1}{2}$  in. diam., straight or forked, with few or no lateral branches: sts. 3–8 ft. long, rigid and erect at base but requiring support above: lvs. mostly 5 and 6 at a node, alternate above, cordate, repand, green on both sides, glabrous: staminate fls. panicle, the clusters solitary in the axils; pistillate fls. few in the cluster: fr. variable,  $\frac{1}{2}$ –1  $\frac{1}{2}$  in. long. Woods and banks, N. C. to Fla., La., Mo. and Ark.—*D. glauca*, Muhl. Rhizomes  $\frac{1}{2}$  in. or more diam., often forked and with many short lateral branches (the source of the drug "dioscorea"): st. 3–10 ft. long, rigid and erect at base but requiring support above: lvs. in whorls of 5–7, the upper ones alternate, larger than in *D. quaternata* and less or not at all repand glabrous or hirtellous, glaucous at maturity: staminate infl. solitary in all axils, paniculate; pistillate infl. few-fld.: fr. to 1  $\frac{1}{4}$  in. long. Pa. southward along the mts. to S. C. and west to E. Mo.—*D. paniculata*, Michx. Rhizomes long and slender, simple or rarely forked, less than  $\frac{1}{2}$  in. diam., with a few short thinner laterals: st. 3–14 ft., flexuose, glabrous: lvs. all alternate or nearly so, pubescent beneath: staminate infl. solitary in the upper axils; pistillate infl. densely many-fruited: fr. less than 1 in. Var. *glabrifolia*, Bartlett, has glabrous lvs. Mass. to Minn., south to Texas in the middle region.—*D. hirticaulis*, Bartlett. Rhizome less than  $\frac{1}{2}$  in. diam., simple or rarely forked, nearly

straight, with short thin laterals: st. 3-10 ft., weak and flexuose, pubescent: lvs. all alternate (except perhaps at lowest node), grayish pubescent: staminate infl. solitary in upper axils, the upper ones paniculate; pistillate infl. with 1-4 frs., which are nearly 1 in. long. Carolinas and Ga.—*D. floridana*, Bartlett. Rhizomes undescribed: st. flexuose and twining; lvs. alternate, wholly glabrous, green above and paler beneath: staminate infl. paniculate, in the upper axils and also terminal; pistillate infl. solitary, 5-7-fld.; fr. similar to those of *D. paniculata*, nearly 1 in. long, S. C. to Fla.

Of the many names appearing in horticultural literature, the following are recent: *D. argyrea*, Hort. Lvs. with silver-gray angular patches along the main nerves. Colombia. Probably one of the *D. discolor*-multicolor group.—*D. bicolor*, Hort. Greenhouse climber, with ovate and cordate lvs., variegated above and deep purple beneath. G.W. 13, p. 254. Perhaps a garden form of some species, although there is a *D. bicolor*, Prain & Burkill described in a Bengal Journal.—*D. Fargesii*, Franch. Twining, with spherical aerial tubers: lvs. of 3-5 parts or lfts., ternate or digitate, the parts oval or oval-lanceolate, more or less acuminate; female fls. in a very long cluster, sessile, subtended by lanceolate bracts; female fl. oblong, with 6 short segms.: subterranean tuber globular, said to be edible; plant produces aerial tubers. W. China. R.H. 1900, p. 685.—*D. globosa*, Roxbg. Cult. by Hindoos: tubers large, round and white; sts. 6-winged, prickly toward the root; lvs. sagittate-cordate, ensiform, 5-7-nerved, the long petiole 5-winged; staminate infl. long-pendulous and compound, and verticillate; pistillate infl. simple and erect in the axils, few-fld. India. This name is listed in Eu.—*D. illustrata*, Hort., appears in European lists: lvs. satiny green with a central band of gray, transverse lines of white, and gray patches, under surface purple. Brazil. Probably one of the *D. discolor* group.—*D. japonica*, Thunb. St. slender, climbing 10-12 ft.: lvs. ovate with tapering apex and deeply cordate base, with some of the axils bearing small oblong tubers or bulbels: pistillate fls. small, white, racemose near the top of the plant; fr. triangular, winged; root 3-4 ft. long, 1-2 in. diam., often branched. Japan. Cult. forms have thicker and more condensed roots, and are eaten after the manner of potatoes. Offered abroad.—*D. macrocarpa*, Harms. Lvs. simple, alternate, glabrous, stalked, cordate-ovate, 1 ft. each way, undulate, with an apical cusp  $1\frac{1}{2}$ -2 in. long; male fls. in a large panicle, the racemes reaching 2 ft., the fertile stamens 6 and very short. Upper Guinea (Trop. Afr.).—*D. retusa*, Mast. Sts. slender, much twining, finely pubescent; lvs. alternate, compound; lfts. 5, flat, few, in short-peduncled racemes; perianth-segms. oblong and connivent; fertile stamens 3 and staminodea 3. S. Afr. G.C. 1870: 1149. G.Z. 22, p. 242.

L. H. B.

**DIÓDMA** (Greek, *divine odor*). *Rutaceæ*. Small tender heath-like shrubs from southwestern Africa.

Leaves alternate or opposite, linear-acute, channeled, serrulate or sometimes ciliate, glandular

dotted: fls. white or reddish, terminal, subsolitary or corymbose, pedicellate; calyx 5-parted; hypogynous disk 5-sinuate, 5-plaited; petals 5; style short; stigma capitate: carpels 5.—Of the more than 200 species described, barely a dozen now remain in this genus, the others

being mostly referred to allied genera, especially *Adenandra*, *Agathosma* and *Barosma*.

The plant known to gardeners (and described by Linnæus) as *D. capitata* is now referred to *Audouinia capitata*, Brongn., which belongs in a different order (*Burseraceæ*) and even in a different subclass of the Dicotyledons (genus named for J. V. Audouin, born 1797, famous entomologist). It is a heath-like shrub 2-3 ft. high, with erect branches, and somewhat whorled, mostly clustered branchlets: lvs. spirally arranged, stalkless, overlapping, linear, 3-

angled, roughish, with 2 grooves beneath: fls. crimson (according to *Flora Capensis*), crowded into oblong spike-like, terminal heads. Generic characters are: calyx adhering to the ovary, 5-cleft, segms. large, overlapping; petals with a long, 2-keeled claw, and a spreading, roundish limb; stamens included; ovary half inferior, 3-celled, cells 2-ovuled; style 3-angled, with 3 small, papilla-like stigmas.—One species.

In America, *D. ericoides* is more or less well known, and is put to various uses in floral decorations, in sprays, or branchlets cut to the required length, and stuck in formal designs as a setting for other flowers in the same manner and for the same purpose as *Stevia* is used, to give that necessary grace and artistic effect to the whole. This species, like most of the genus, has an agreeable aromatic fragrance in the foliage. It is a strong grower, loose and heath-like in habit and foliage, as the specific name indicates; flowers white and small, one or more on the points of tiny branchlets. While diosmas undoubtedly do best in soil suitable for heaths, that is, soil composed largely of fibrous peat, they are not nearly so exacting in their requirements in this respect, and can be grown in good fibrous loam and leaf-mold in equal parts, with considerable clean sharp sand added thereto. The plants should be cut back rather severely after flowering to keep them low and bushy; this refers more particularly to the above species, other members of the genus being of more compact growth and needing very little corrective cutting to keep them in shape. *D. capitata* (properly *Audouinia capitata*) is a fine example of the latter class, and is much better than *D. ericoides* for exhibition and show purposes; flowers pinkish lilac, in corymbs. The propagation of diosmas by cuttings is similar to that of heaths, but much easier. The best material for cuttings is young wood. (Kenneth Finlayson.)

*ericoides*, Linn. Much-branched, 1-2 ft., leafy: branches and twigs quite glabrous: lvs. alternate, crowded, recurved-spreading, oblong, obtuse, keeled, pointless, glabrous: fls. terminal, 2-3 together, with very short pedicels; calyx-lobes ovate, obtuse; petals reddish, elliptic-oblong or obovate, obtuse, narrowed to a short claw, twice as long as the calyx; disk free and 5-lobed. B.M. 2332 under this name is in reality *D. vulgaris* var. *longifolia*. G. 33:501.

The plant cult. in Calif. as *Diosma purpurea* belongs to *Agathosma* (Greek, *good odor*), differing from *Diosma* chiefly in the presence of 5 stamens and in the 3 or 4 carpels; it is *A. villosa* Willd., a shrub about 1 ft. high with upright branches, spirally arranged upright and imbricate lvs. oblong-lanceolate, ciliate, pubescent beneath,  $\frac{1}{16}$ - $\frac{1}{8}$  in. long; fls. light purple, in dense terminal heads; pedicels unequal, at least the outer ones not exceeding the lvs. S. Afr. R.B. 5:369 (as *Diosma hirta*), H.I. 1:4. Another species sometimes cult. as *D. purpurea* is *Agathosma Ventenatiana*, Bartl. & Wendl. differing from the preceding species chiefly in the spreading lvs. and in nearly equal pedicels exceeding the lvs. L.B.C. 12:1122 (as *Diosma hirta*).

*D. fragrans*, Sims=*Adenandra fragrans*.—*D. vulgaris*, Schlecht., has narrower lvs. than *D. ericoides*, and they are acute: branchlets minutely pubescent: lvs. scattered, rarely opposite, linear, convex-carinate, subulate-acuminate: fls. corymbose, the petals white, or red on the outside: plant 1-2 or more ft. There are well-marked botanical varieties.

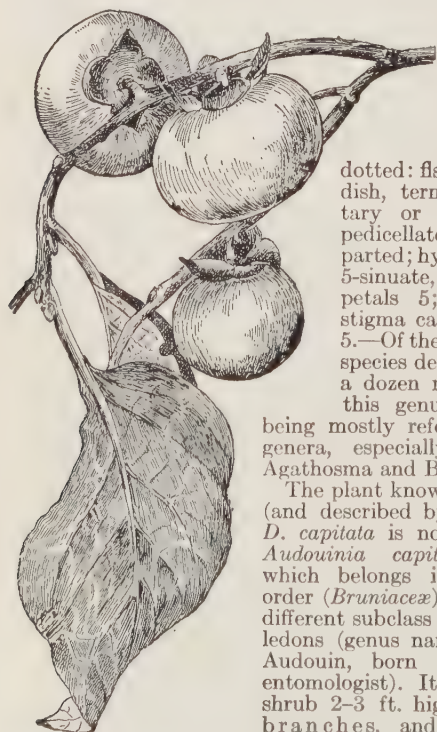

WILHELM MILLER.

L. H. B.†

**DIOSPÏROS** (*Dios*, Jove's, *pyros*, grain; alluding to its edible fruit). *Ebenaceæ*. **PERSIMMON**. **EBONY**. Woody plants grown partly for the handsome foliage and partly for their edible fruits; some species are valuable timber trees.

Deciduous or evergreen trees or shrubs, with alternate, rarely opposite, entire lvs., without stipules: fls. dioecious or polygamous in few- or many-fld., axillary cymes, the pistillate often solitary, yellowish or whitish; calyx and corolla 3-7-, usually 4-lobed; stamens usually 8-16, included; styles 2-6; ovary 4-12-celled: fr. a large, juicy berry, 1-10-seeded, bearing usually the enlarged calyx at the base; seed flat, rather large.—About 190 species in the tropics, few in colder climates.

The few cultivated species are ornamental trees,

1271. Native persimmon, *Diospyros virginiana*. ( $\times \frac{1}{4}$ )

with handsome lustrous foliage, rarely attacked by insects and with decorative and edible fruit. The only species which is tolerably hardy North is *D. virginiana*, while *D. Kaki*, much cultivated in Japan for its large edible fruits, is hardy only in the southern states. Most species have valuable hard and close-grained wood,

1272. *Diospyros Lotus*. ( $\times \frac{3}{8}$ )

and that of some tropical species is known as ebony. They thrive in almost any soil, but require, in cooler climates, sheltered and sunny positions. Propagated by seeds to be sown after maturity or stratified and sown in spring, and by cuttings of half-ripened wood or by layers; the tropical species by cuttings of mature wood in spring, with bottom heat; the fruit-bearing varieties are usually grafted or budded on seedling stock of *D. virginiana*. See *Persimmon*.

A. *Lvs. acuminate*.

B. *Fr.*  $\frac{1}{2}$ – $1\frac{1}{2}$  in. across, not ribbed: branches usually glabrous.

**virginiana**, Linn. COMMON PERSIMMON. Fig. 1271. Tree, to 50 ft., rarely to 100 ft., with round-topped head and spreading, often pendulous branches: lvs. ovate or elliptic, acuminate, shining above, glabrous at length or pubescent beneath, 3–6 in. long: fls. short-stalked, greenish yellow, staminate in 3's,  $\frac{1}{2}$  in. long, with 16 stamens; pistillate solitary, larger, with 4 2-lobed styles, connate at the base: fr. globose or obovate, plum-like, with the enlarged calyx at the base, 1– $1\frac{1}{2}$  in. diam., pale orange, often with red cheek, edible, varying in size, color and flavor. June. Conn. to Fla., west to Kans. and Texas. S.S. 6:252, 253. G.F. 8:265. Mn. 4:21. Gn. 57, p. 146. A.G. 11:651. V. 4:20. G.W. 16:230.

**Lôtus**, Linn. Fig. 1272. Round-headed tree, to 40 ft.: lvs. elliptic or oblong, acuminate, pubescent, often glabrous above at length, 3–5 in. long: fls. reddish white, staminate in 3's, with 16 stamens, pistillate solitary: fr. yellow at first, black when fully ripe, globular,  $\frac{1}{2}$ – $\frac{3}{4}$  in. diam., edible. June. W. Asia to China. A.G. 12:460. Gn. 32, p. 68. S.I.F. 1:79.

BB. *Fr.*  $1\frac{1}{2}$ –3 in. across, usually ribbed: branches with appressed brownish pubescence.

**Kâki**, Linn. f. (*D. chinensis*, Blume. *D. Schitse*, Bunge. *D. Roxburghii*, Carr.). Fig. 1273. Tree to

40 ft., with round head: lvs. ovate-elliptic, oblong-ovate or obovate, acuminate, subcoriaceous, glabrous and shining above, more or less pubescent beneath, 3–7 in. long: fls. yellowish white, staminate with 16–24 stamens, pistillate to  $\frac{3}{4}$  in. long; styles divided to the base, pubescent: fr. large,  $1\frac{1}{2}$ –3 in. across, very variable in shape and size, mostly resembling a tomato, orange or reddish. June. Japan, China. R.H. 1870, pp. 412, 413; 1872, pp. 254, 255. B.M. 8127. G.C. III. 41:22. Gn. 27, pp. 168, 169; 49, p. 171. M.D.G. 1909: 409. Var. **costata**, André. Fr. large, depressed, globular, orange-red, with 4 furrows. R.H. 1870:410, and p. 133. I.H. 18:78. G.C. II. 4:777; III. 9:171; 13:51. Gn. 49, p. 171. Var. **Mazélii**, Mouillef. Fr. orange-yellow, with 8 furrows. R.H. 1874:70. Other varieties are figured in R.H. 1872, p. 254; 1878:470; 1887:348; 1888:60. A.G. 12:331–8, 459–462.—A very desirable and beautiful fruit-bearing tree for the southern states, where a number of different varieties intro. from Japan are cult., but the hardier varieties from the north of Japan and China, which are likely to be hardy north to New England, seem hitherto not to have been intro. Fig. 1273 is from Georgeson's articles in A. G. 1891.—The plant cult. in Eu. as *D. chinensis*, which is apparently the same as *D. Roxburghii*, differs from the Japanese forms of Kaki, which usually have elliptic and glabrescent lvs., in the narrower usually oblong lvs. densely pubescent beneath, less so above, and in the greenish yellow subglobose fr.; it is tenderer than the common Kaki. It must not be confused with *D. sinensis*, Hemsl., an entirely different species from Cent. China, not in cult.

AA. *Lvs. obtuse or emarginate*.

**texana**, Scheele (*D. mexicana*, Scheele. *Brayodendron texanum*, Small). Small tree, intricately branched, rarely to 40 ft.: lvs. cuneate, oblong or obovate, pubescent below, 1–2 in. long: fls. with the lvs., pubescent, on branches of the previous year; calyx and corolla 5-lobed; staminate fls. with 16 stamens, pistillate with 4 pubescent styles connate at the base: fr. black,  $\frac{3}{4}$ –1 in. diam. Spring. Texas, New Mex. S.S. 6:254.

**tessellaria**, Poir. (*D. reticulata*, Willd.). Tree or shrub: lvs. coriaceous, oval or oblong, rounded at both ends, lustrous above, glabrous and reticulate below, 3–6 in. long: fls. clustered, sessile; calyx tubular, 4-lobed at the apex; corolla 4-lobed; sta-

1273. A cultivated fruit of *Diospyros Kaki*. (Nearly natural size.)

mens 12-13, glabrous; fr. ovoid, sericeous or glabrate.  $1\frac{1}{4}$ - $1\frac{1}{2}$  in. long, edible. Mauritius.—Yields the ebony of Mauritius. Cult. in S. Calif.

*D. armata*, Hemsl. Spiny tree, to 20 ft.: lvs. persistent, oval-oblong, obtuse, 1-2 in. long; staminate fls. in short panicles, creamy white, fragrant; fr. usually solitary,  $\frac{3}{4}$  in. across, Cent. China. Tender.—*D. Ebenaster*, Retz. The "guayabota" and "zapote negro," from Mex. and W. Indies, has been catalogued in S. Calif. It is a tall tree, with very sweet frs. the size of an orange, green outside and almost black inside; lvs. elliptic or oblong, usually obtuse, 3-12 in. long; fls. white, fragrant.—*D. Ebenum*, Koenig. Tree, to 50 ft.: lvs. elliptic-oblong, bluntly acuminate, glabrous; fls. white, staminate, in short racemes. E. Indies, Ceylon. For cult. in hothouses or tropical climates. This species is said to yield the best ebony.—*D. Morrisiana*, Hance. Evergreen shrub or small tree, glabrous; lvs. oval, obtusely acuminate, 2-3½ in. long; fls. whitish, drooping, on hairy stalks; fr. yellow, subglobose,  $\frac{1}{2}$ -¾ in. across. Hongkong, Formosa. The edible fr. ripens in Dec.—*D. utilis*, Hemsl. Evergreen large tree; branchlets silky-pubescent; lvs. oblong, short-petioled, glabrous above, whitish and silky-pubescent beneath, 5-8 in. long; fr. depressed-globose, pubescent, nearly 2 in. across. Formosa. The edible fr. is called Mao-shih.

ALFRED REHDER.

**DIOSTEA** (probably *two stones* or *seeds*). *Verbenaceae*. Once referred to *Baillonia*, but now kept distinct; closely allied to *Lippia*, but differing widely in habit, in the slender green branches, in the branchlets having very long internodes and being cylindric and hollow. *D. juncea*, Miers, of the Andes of Chile and Argentina, is a bush or small tree, with the long branches constricted when dry; lvs. opposite, 1 in. or less long, sessile, oblong or ovate-oblong, obtuse, crenate, rather fleshy; fls. small, pale lilac, in peduncled axillary or terminal spikes; corolla tubular, inflated above the middle, hairy inside, with 5 very short rounded spreading lobes; stamens 4, didynamous. B.M. 7695.

**DIOTIS** (*two-eared*, denoting the structure). *Compositae*. One cottony perennial on sea sands of Eu., sometimes planted in rock-gardens and for edgings. *D. candidissima*, Desf. (*D. maritima*, Smith). *COTTON-WEED*. Usually less than 1 ft. high, has hard sts. almost woody at base, arising from a creeping rootstock; lvs. alternate, oblong, entire or slightly toothed, about ½ in. long; fl.-heads nearly globular, ½ in. across, in dense terminal clusters, in Aug. and Sept. It is readily prop. by seeds or cuttings. *Diotis* is closely allied to *Achillea*, being distinguished by the florets being all tubular and having 2 ears at the base of the corolla which persist and inclose the achene.

**DIPCADI** (meaning uncertain). Including *Tricharis* and *Uropetalum*. *Liliaceae*. Tender bulbous scapose plants of minor importance, allied to *Galtonia*.

Leaves radical, thickish, narrowly linear: scape simple and leafless, bearing loose racemes of odd-colored fls.; perianth with a cylindrical tube, the lobes mostly equaling or exceeding the tube, the 3 exterior ones spreading or flaring and the 3 interior usually shorter and erect; stamens 6, on the throat of the perianth, the anthers linear and attached by the back; ovary sessile, ovoid or oblong, becoming a 3-sided dehiscent caps.: bulb tunicated.—About 50 species in S. Eu., Trop. and S. Afr. and India. During the winter, their resting time, the bulbs should be kept dry. A compost of light, sandy loam and leaf-mold has been recommended. Many species have been described in recent years from Trop. and S. Afr., and some of them may be expected to appear in the trade, and in lists of novelties.

A. *All perianth-segms. equally long.* (*Tricharis*.)

**serotinum**, Medikus. Lvs. 5-6, fleshy-herbaceous, glabrous, narrowly linear, 6-12 in. long, 2-3 lines wide near the base, channeled on the face; scape 4-12 in. long; raceme loose, 4-12-flid.; bracts lanceolate, 4-6 lines long, longer than the pedicels; perianth greenish brown, 5-6 lines long; ovary sessile or subsessile. S. Eu., N. Afr. B.M. 859 (as *Scilla serotina*).

AA. *Outer perianth-segms. longer than the inner and tailed.* (*Uropetalum*.)

**filamentosum**, Medikus (*D. viride*, Moench). Lvs. 5-6, fleshy-herbaceous, narrowly linear, glabrous, 1 ft. long,  $1\frac{1}{2}$ -3 lines wide near the base; scape 1-2 ft. high; raceme loose, 6-15-flid.; bracts linear-acuminate, 4-6 lines long; perianth green, 12-15 lines long, outer segms. 4-6 lines longer than the inner: caps. sessile or nearly so. S. Afr.

WILHELM MILLER.  
L. H. B.†

**DIPÉLTA** (Greek *dis*, twice, and *pelte*, shield; two of the floral bracts are shield-like). *Caprifoliaceae*. Ornamental deciduous shrubs, grown for their handsome pinkish or purple flowers.

Leaves opposite, short-petioled, entire or denticulate, without stipules; fls. solitary or in leafy few-flid. racemes, with 4 unequal conspicuous bracts at the base; calyx-lobes linear or lanceolate, 5; corolla tubular-campanulate, 2-lipped; stamens 4, inclosed; style slender, shorter than corolla; ovary inferior, elongated, 4-celled, 2 of the cells with 1 fertile ovule each and 2 cells with several sterile ovules; fr. a caps. inclosed by the enlarged, usually shield-like, bracts.—Four species in Cent. and W. Asia.

Dipeltas resemble diervillas in habit, with handsome pinkish or purple flowers in clusters along last year's branches; the flowers in shape are like those of a large-flowered abelia. *D. floribunda* has proved hardy at the Arnold Arboretum, while *D. ventricosa* seems to be somewhat tenderer. They are apparently not particular as to the soil. Propagation is by seeds sown in spring and probably, like *Abelia* and *Diervilla*, by greenwood and hardwood cuttings.

**floribunda**, Maxim. Shrub, to 15 ft.: lvs. ovate to lanceolate, acute or acuminate, rounded or narrowed at the base, entire, puberulous at first, soon glabrous, 2-4 in. long; fls. 1-6, on slender nodding pedicels, tubular-campanulate, pale rose, lower lip with orange marks,  $1\frac{1}{4}$  in. long; ovary inclosed by the 2 upper large shield-like bracts persisting on the fr. and  $\frac{3}{4}$ -1 in. across. May. Cent. China. B.M. 8310. G.C. III. 42:3. M.D.G. 1912:27.

**ventricosa**, Hemsl. Shrub, to 18 ft.: lvs. ovate-lanceolate to lanceolate, long-acuminate, usually rounded at the base, remotely glandular-denticulate, sparingly hairy above and villous along the veins beneath, 2-6 in. long; fls. 1-4 on drooping slender pedicels, campanulate, ventricose and scarcely tubular at the base, outside purple, whitish inside and marked with orange,  $1\frac{1}{4}$  in. long; ovary hidden by 2 large unequal auriculate bracts on the fr. about  $\frac{3}{4}$  in. across. May, June. W. China. B.M. 8294. G.C. III. 44:101.

*D. yunnanensis*, Franch. Allied to *D. ventricosa*. Lvs. entire; corolla distinctly tubular at the base. W. China. R.H. 1891, p. 246. Not yet intro.—*D. elegans*, Batal, is another handsome species not yet in cult.

ALFRED REHDER.

**DIPHYLLEIA** (Greek, *double leaf*). *Berberidaceae*. **UMBRELLA-LEAF**. An interesting hardy perennial herb, sometimes transferred to the wild-garden.

Plant with thick creeping jointed knotty rootstocks, sending up a huge peltate cut-lobed umbrella-like radical lf. on a stout stalk, and a flowering st. bearing 2 similar (but smaller and more 2-cleft) alternate lvs., which are peltate near one margin, and a terminal cyme of white fls.: sepals 6, fugacious; petals and stamens 6; ovules 5 or 6; berries globose, few-seeded. This is one of the genera having only 2 species, one of which is found in N. E. N. Amer., the other in E Asia or Japan, of which there are two others in this family.

**cymosa**, Michx. Root-lvs. 1-2 ft. across, 2-cleft, each division 5-7-lobed; lobes toothed: st. 1-4 ft. tall; berries blue. May. Wet or springy places in mountains from Va. to Ga. B.M. 1666.—Grows readily in dry soil under cult. but is dwarf.

**DIPHYSA** (*two bladders*, because of the structure of the pod). *Leguminosæ*. Shrubs or trees, usually glandular, with odd-pinnate lvs. and papilionaceous fls., of about 10 or 12 species in Mex., Cent. Amer., to Venezuela, rarely seen in cult. abroad in warmhouses: calyx with 5 unlike teeth, the 2 upper short; standard of the corolla orbicular, clawed, with 2 callosities inside; wings obovate or oblong or nearly lanceolate; keel as long as the wings or somewhat longer: fr. a stipitate more or less inflated pod: fls. yellow, in short racemes or fascicles. *D. carthagenensis*, Jacq., is a shrub or small unarmed tree, with 2-3-fld. axillary peduncles, and about 5 pairs of lfts. *D. floribunda*, Peyr., has been offered in S. Calif.: much-branching shrub: lvs. alternate; lfts. 7-13, elliptic or broad-oblong, the mid-nerve ending in a mucro: fls. yellow, in short secund racemes; standard strongly reflexed,  $\frac{1}{2}$  in. broad. S. Mex.

L. H. B.

**DÍPIDAX** (*double fountain*, from the pair of nectaries at the base of the perianth-segms.). *Liliacæ*. Two species in S. Afr., with tunicated corms, simple sts. and small whitish more or less tinted fls. in spikes, of little horticultural importance: perianth deciduous, polyphyllous; stamens 6, included; ovary sessile, 3-celled and 3-lobed, many-ovuled; styles 3, awl-shaped: fr. a turbinate 3-valved caps. *D. ciliata*, Baker. St. 6-12 in.: lvs. usually 3, ciliate, the lower 4-6 in. long and lanceolate-acuminate and the upper much shorter and amplexicaul: spike 2-6 in. long, densely many-fld.; fls. whitish more or less tinged red: there are several botanical vars., differing in lvs., number and color of fls. *D. triquetra*, Baker. St. 12-18 in.: lvs. 3 not ciliate, the lowest at base of st. and the upper near the spike (which is 1-6 in. long): fls. with numerous brown veins and 2 purple nectar-spots. B.M. 558 (as *Melanthium triquetrum*). The species are treated as greenhouse perennials.

**DÍPLACUS:** *Mimulus*.

**DIPLADÈNIA** (Greek, *double gland*, referring to the two glands at base of ovary, which distinguish this genus from *Echites*). *Apocynacæ*. A charming genus of greenhouse twiners (sometimes erect), mostly from Brazil.

Flowers large, showy, more or less funnel-shaped, having a remarkable range of color, rarely white or dark red, but especially rich in rosy shades and with throats often brilliantly colored with yellow; the buds, also, are charming; calyx 5-parted, the lobes lanceolate, with glands or scales in the inside; corolla without scales at the throat, the 5 lobes spreading, twisted in the bud; stamens 5, affixed in the top of the tube, included, the acuminate anthers connivent around the 5-lobed stigma; disk of 2 fleshy scales, alternating with the 2 distinct ovaries: fr. of 2 terete more or less spreading follicles.

Species 30-40, in Trop. S. Amer., woody (rarely herbaceous) and mostly at first erect but becoming scandent, the lvs. mostly opposite and entire and usually with bristles or glands at base; fls. usually in terminal or axillary racemes. The genus is fully as interesting as *Allamanda*, which belongs to

another tribe of the same family. Other allied genera of garden interest are *Echites*, *Odontadenia*, *Mandevilla* and *Urechites*. Some species are naturally erect bushes, at least when young, and many can be trained to the bush form. The group is a most tempting one to the hybridizer. Many names appear in European catalogues, but they are confused. Very many pictures are found in the European horticultural periodicals.

Of the twining glasshouse flowering subjects, dipladenias are amongst the best and ought to be in all collections of greenhouse plants. An erroneous idea is held by many that it is necessary to have a very high temperature to grow these plants successfully. This, however, is not the case. Except when started into active growth in the early spring, they do better in an intermediate temperature. Dipladenias have been known to live, and thrive well, after having been subjected to 7° of frost. A good time of the year to secure cuttings of dipladenias is about February 1. At that time they show signs of starting into growth and the weak wood should all be pruned back to the normal thickness of the stem. The thickest part of these prunings make good cuttings. Take a piece with two leaves attached, with about an inch of the stem under the leaves. Pot them singly in small pots, half filled with equal parts osmundine, broken up rather fine, sand, and charcoal. Fill the upper part of the pot with sand. Place the pots in a tight propagating bed, in a night-temperature of 70°. Allow the temperature to run up to 80° or more by day, but be sure and admit air several times during the day by opening up the case the plants are in for a few minutes. The cuttings will have the small pots filled with roots in about a month, when they may be shifted into larger pots. From now on, use for potting equal parts of osmundine, the fiber of loam out of which all the fine part has been shaken, sphagnum moss, sand and charcoal. When the plants reach a 6-inch pot, a sixth part of sheep-manure may be added and a sprinkling of chicken-bone. It is a good plan, provided one has a good sheltered border with a southern aspect, to plant small plants of dipladenia outdoors from June until the middle of September. It is astonishing how vigorously they start into growth and flower when potted after this treatment. Fifty-five degrees is a good night temperature to grow dipladenias in when possible. During the summer, if grown indoors, admit all the air that can be admitted day and night. They will stand the full sun under glass, but they do slightly better under a very light shade during the hotter part of the day, when the sun is shining. When the pots are filled with roots, and it is desired that they should remain in that pot for the rest of the season, feed with manure-water, a handful of cow-manure to a two-and-a-half-gallon watering-pot. The same amount to an equal quantity of water if a fertilizer such as "Clays" is used, is sufficient. Horse urine may also be used for a change, a 3-inch potful to two and one-half gallons of water. Be sure to water three times in between with clean water. Dipladenias show signs of completing their growth toward the end of November, at which time water should be gradually withheld, but never so as to allow the wood to shrivel. They may be treated in this manner until the end of January, when, as stated above, they will show signs of starting the season's growth. At this season they should have a general overhauling. Large plants should be turned out of their pots, and the loose dirt all washed out of them with a hose with a gentle pressure on it; and if possible repot in the same size of pot. After disturbing the roots in this manner, they are better to be placed for a few weeks in a temperature of not less than 65°. When they have gripped the new soil, they do better in 55° night temperature. Give each break a piece of thread attached from the plant to the roof to climb on until they set flower. A few breaks, near the highest part of the plant, will

1274. *Dipladenia atropurpurea*. (×  $\frac{1}{2}$ )

start climbing ahead of the others, and after they show a flower-stem pinch the shoot immediately ahead of the flower. This will encourage the belated breaks to start and catch up to these leaders. When they have all set flower, they may be trained evenly over a globe trellis if they are desired for a specimen plant. By the above treatment ninety-five open flowers, all at one time, have been secured on a plant in a 12-inch pot. Dipladenias are subject to mealy-bug, scale, thrips, and red-spider. Fumigate with hydrocyanic gas during the cold months, and syringe regularly and thoroughly during the summer, and these pests will give no trouble. (George F. Stewart.)

A. Fls. white; throat yellow inside.

**boliviensis**, Hook. Plant everywhere glabrous: st. slender: lvs. petioled, 2-3½ in. long, acuminate, acute at base,

1275. *Dipladenia splendens*. (×¼)

bright green and glossy above, pale beneath; stipules none: racemes axillary, 3-4-fld.; peduncles much shorter than the lvs., about as long as petioles and pedicels; bracts minute at the base of the twisted pedicels; calyx-lobes ovate, acuminate, 3 lines long; corolla almost salver-shaped, tube and throat slender and cylindrical, the former ½ in. long, the latter twice as long and half as broad again; limb 1½ in. across; lobes broadly ovate, more acuminate than in *D. atropurpurea*. Bolivia. B. M. 5783. Gn. 44: 140. Gng. 7:342.

AA. Fls. dark purple.

**atropurpurea**, DC. (*D. Marie Henriette*, Hort.). Fig. 1274. Glabrous: lvs. ovate-

acute, about 2 in. long, acute at the very base: racemes axillary, 2-fld.; peduncles a little longer than the lvs.; pedicels twisted, bracted; calyx-lobes lanceolate-acuminate, a little shorter than the pedicel, and a third as long as the cylindrical part of the corolla (of which the tube is about 2 in. long); corolla dark purple inside and out, tube funnel-shaped above the middle; lobes triangular, wavy, spreading, shorter than the dilated part of the tube. Brazil. B.R. 29:27 (as *Echites*). Gn. 44:488. I.H. 42:33. Gt. 43, p. 548. Var. *Clárkei*, Hort. Lvs. rather small: fl. deep crimson shaded velvet-black, about 2½ in. across, the tube paler. Gn. W. 8:661.—*D. atropurpurea* is a handsome species, but considered to be a shy bloomer.

AAA. Fls. rose; throat deep rose or purple within, whitish outside.

**spléndens**, DC. (*Echites splendens*, Hook.). Fig. 1275. St. glabrous, the branches terete: lvs. subsessile, 4-8 in. long, elliptic-acuminate, cordate at the base, wavy, pubescent, especially beneath, veins elevated, numerous: racemes axillary, longer than the lvs., 4-6-fld.; calyx-lobes red-tipped, awl-shaped, as long as the cylindrical part of the corolla-tube, which is half the length of the funnel-shaped portion; limb flat, 4 in. across, the lobes rotund, subacute, almost as long

as the tube; corolla-tube 1½ in. long, white outside, lobes rosy, throat deeper, almost purple. Brazil. B.M. 3976. F.S. 1:34 shows a yellow-throated form. Var. **profusa**, Rod. (*D. profusa*, Hort.), has larger and brighter rosy fls., lined with yellow inside, the outside of the tube rosy except at the base, which is yellow. J.H. III. 57:277. I.H. 30:491.—Intro. by B. S. Williams. *D. amabilis*, Hort., is said to be a hybrid of *D. crassinoda* and *D. splendens*. Lvs. short-stalked, oblong, acute: fls. rosy crimson, 4-5 in. across; corolla-lobes very round and stiff. Gn. 51, p. 227. G. 12:89; 14:461. I.H. 27:396, shows a 12-fld. raceme with exceptionally bright red fls.

AAAA. Fls. salmon-colored; throat yellow inside and out.

**urophýlla**, Hook. Glabrous erect bush, not a vine: branches numerous, swollen at the joints: lvs. ovate-oblong, obtuse at the base, suddenly narrowed at the apex into a narrow point ¾ in. long; peduncles long, drooping, flexuose; racemes axillary, 4-6-fld.; calyx-segms. awl-shaped; corolla dull yellow outside, deeper and brighter yellow within; tube cylindrical in lower third, then swelling into an almost bell-shaped throat; lobes of the limb salmon inclined to purple, acute. Brazil. B.M. 4414. P.M. 16:66. F.S. 5:425.

*D. amena*, Moore. Free-flowering, with good foliage: lvs. oblong-acuminate: fls. pink tinted with rose; corolla-lobes rounded and not reflexed. Of garden origin (*D. splendens* × *D. amabilis*); offered abroad. F. 1868:73. G. 6:391; 11:43.—*D. Brearleyana*, Hort. Lvs. oblong, acute, dark green: fls. pink at first, changing to rich crimson, very large. Gn. 51, p. 226. F.W. 1875:161. G. 8:92; 12:703. Probably a form of *Odontadenia speciosa*.—*D. carissima*, Hort. Fls. very large (about 5 in. diam.), delicate pink lined with bright rose. Garder origin. G.Z. 27, p. 49.—*D. crassinoda*, DC. Glabrous: st. much knotted, with many nodes: lvs. lanceolate, acute or almost acuminate, acute at the base, shining and leathery on both sides: racemes axillary, about 6-fld.; calyx-lobes lanceolate, acuminate, a little shorter than the cylindrical part of the corolla-tube, 2 or 3 times shorter than the pedicel; corolla-tube bell-shaped above the middle; lobes obovate-orbicular. Brazil. The above is the original description by De Candolle, who adds that the lvs. are 3-3½ in. long, ¾-1 in. wide; petiole 2-3 lines long; stipules interpetiolar, with 4 short cuspidate teeth. The plant pictured in B.R. 30:64 was renamed *D. Lindleyi* by Lemaire chiefly for its pilose st. and stellate-lobed stipules. Later authorities refer B.R. 30:64 to *D. Martiana*. F.S. 22:2310 may be the same plant as B.R. 30:64, but with variable lvs. and stipules. The plant was prized for its delicate colors, being white at first, then shot with soft rose like a flame tulip, and finally a deep rose. Only 1 fl. in a raceme was open at a time, and each lasted 8 or 9 days; throat orange inside.—*D. extima*, Hemsl. Very slender, twining, nearly glabrous, the st. rose-red: lvs. opposite, very short-stalked, 1-1½ in. long, orbicular-ovate to elliptic: fls. 6-8 in a cyme, 2½-3 in. across, rose-colored, the tube nearly 2 in. long, corolla-lobes orbicular and obtusely cuspidate. Probably Brazil. B.M. 7720.—*D. Java*, Hook. Fls. size and color of common yellow allamanda; climbing: lvs. opposite, short-stalked, ovate to elliptic: fls. 4-6 in a lax cyme, yellow, the tube very hairy on the outside and suddenly enlarged above. Colombia. B.M. 4702. J.F. 4:373. See *Urechites*, to which this is properly referred.—*D. Harrisii*, Hook. = *Odontadenia speciosa*.—*D. hybrida*. Lvs. large, stout, bright green: fls. flaming crimson-red. Garden form. G. 32:647.—*D. illustris*, DC. Glabrous or pubescent: lvs. oblong or rotund, obtuse or nearly acute, rounded or subcordate at the base, many-nerved; stipules none; petiole short: racemes terminal, 4-8-fld.; fls. rosy, throat yellow inside, purple at the mouth; corolla-tube cylindrical to the middle, then funnel-shaped; limb 3-3½ in. across, lobes rosy, orbicular-ovate, obtuse. Brazil. F.S. 3:256. Var. *glabra*, Muell. Arg. B.M. 7156.—*D. insignis*, Hort. Stout-growing: foliage strong: fls. rosy purple. Of garden origin. R.H. 1904, p. 419. G.Z. 16:145.—*D. pastorum*, Mart., var. *tenuifolia*, Hook. f. A very slender tuberous-rooted glabrous twining herb with very narrow (½ in. or less broad) lvs. 2-3 in. long, and rose-colored fls. 1½ in. across and bearing a golden 5-cleft ring at the throat. Brazil. B.M. 7725.—*D. Sánderti*, Hemsl., has flesh-colored, fls. with throat yellow inside, and outside at the base, has smaller lvs. than *D. illustris*, and no circle of purple at the mouth of the fl. Gn. 51:226.

WILHELM MILLER.

L. H. B.†

**DIPLARRHENA** (Greek, *two anthers*; the third being imperfect). *Iridaceæ*. Tender rhizomatous plants from Australia and Tasmania, with white and variegated flowers. Herbs: rhizome short: sts. erect, simple or somewhat branched: lvs. mostly radical, narrow, rigid, acuminate, equitant: spathe terminal, rigid, acuminate; perianth without any tube above the ovary; segms. unequal, inner ones shorter, connivent; upper stamen imperfect; fls. usually more than 1 to a spathe, not lasting.

**Moræa**, Labill. Sts.  $1\frac{1}{2}$ –2 ft. long, with a single terminal cluster, and several sheathing bracts: lvs. 6–8 in a tuft,  $1\frac{1}{2}$  ft. long,  $\frac{1}{4}$ – $\frac{1}{2}$  in. wide: spathes cylindrical, 2–3-fld., 2 in. long; fls. whitish: caps. 1 in. long. New S. Wales, Victoria, and Tasmania. This species has been offered. The only other species is *D. latifolia*, Benth. (*D. Moræa* var. *latifolia*, Baker), from Tasmania, with longer and broader lvs. (nearly 1 in. wide), longer spathes which are 5–6-fld., and fls. variegated with lilac and yellow.

L. H. B.

**DIPLAZIUM** (Greek, doubled). *Polypodiaceæ*. Rather large, coarse ferns, of greenhouse culture.

Allied to *Asplenium*, but with the indusia often double, extending along both sides of some of the free veins. The dividing line between *Diplazium* and *Asplenium* is technical. In general appearance and in cultural requirements, the two genera are practically identical.—Eighty or more species are found, mostly in the warmer portions of the world.

A. Lvs. simple.

**lanceum**, Presl. Lvs. 6–9 in. long,  $\frac{3}{4}$ –1 in. wide, narrowed upward and downward, the margin mostly entire; sori reaching nearer to the edge than the midrib. India, China, Japan.

AA. Lvs. pinnate, with the pinnae deeply lobed: rootstock not rising to form a trunk.

**arboreum**, Presl (*Asplenium arboreum*, Linn.). Lvs. 12–18 in. long, 6–8 in. wide, with a distinct auricle or lobe at the base. The habit is not arboreous, as originally supposed, and as the name would indicate; quite near the next, but less deeply cut. W. Indies and Venezuela.

**Shépherdii**, Link (*Asplenium Shépherdii*, Spreng.). Lvs. 12–18 in. long, 6–9 in. broad, deeply lobed, the lobes at the base sometimes reaching down to the rachis, somewhat toothed and often  $\frac{1}{4}$  in. broad; sori long-linear. Cuba and Mex. to Brazil.

AAA. Lvs. bipinnate: trunk somewhat arborescent.

**maximum**, C. Chr. (*D. latifolium*, Moore. *Asplenium latifolium*, Don). St. erect, somewhat arborescent: lvs. 3–4 ft. long, 12–18 in. wide, with about 12 pinnae on either side. India, China and the Philippines.

L. M. UNDERWOOD.

**DIPLOGLÓTTIS** (double-tongued, referring to the divided scale inside the petals). *Sapindaceæ*. Australian tree; one species: *D. australis*, Radlk. (*D. Cunninghamii*, Hook. f.), mentioned in recent horticultural literature. Lvs. large (1–2 ft. or more), pinnate, more or less villous; lfts. 8–12, oblong-elliptic to ovate-lanceolate, sometimes more than 1 ft. long; fls. greenish, many, in a large panicle; calyx deeply 5-lobed, small; petals about twice as long as calyx ( $\frac{1}{4}$  in.), 4, thin, orbicular, ciliate, about equaled by the 2 inner scales; stamens 8, exserted or included; ovary 3-celled, the style short and incurved, stigma entire or somewhat 3-lobed: fr. a nearly globular 3-valved caps., tomentose, about  $\frac{1}{2}$  in. diam. B.M. 4470 (as *Cupania Cunninghamii*).

**DIPLOLÈNA** (double cloak, in allusion to the double involucre). *Rutaceæ*. W. Australian tomentose shrubs, sometimes cult., but apparently not in American trade. Lvs. simple and entire, stalked, alternate: fls. red from the appearance of the many stamens in the terminal heads which are flower-like and short-peduncled or sessile and surrounded by an involucre of broad bracts in 3 or 4 series of which the inner ones are large and petal-like; calyx wanting; petals 5, small and narrow; disk small; stamens 10, much exserted, the filaments bearded; ovary 5-lobed, the styles united into 1: fr. 2-valved cocci, resulting from the division of the ovary.—About 4 species. *D. grandiflora*, Desf., 5–6 ft., with rigid spreading branches, the ovate or broad-oblong

very obtuse lvs. tomentose or hoary on both sides. *D. Dampieri*, Desf., distinguished chiefly by the lvs being green and smooth on the upper surface. B.M. 4059. B.R. 27:64. H.U. 5:42. L. H. B.

**DIPLOPAPPUS**: *Aster*.

**DIPLOSTÈPHIUM** (double crown or pappus). *Compósitæ*. This genus as now defined comprises upward of a dozen species in Venezuela, Colombia and to Peru, probably not in cult.; the *D. amygdalinum*, Cass., of gardens is *Aster umbellatus*, Mill., under Gray's treatment, and *Dœllingeria umbellata*, Nees, of some other authors. *Dœllingeria* differs from *Aster* proper in its double pappus, the inner bristles long and capillary and the outer short and rigid; involucre-bracts short and lacking herbaceous tips; heads corymbose or solitary; rays rather few, white or rose-tinged: lvs. veiny, not stiff. (Named for Th. Dœllinger, botanical explorer.)

*Aster umbellatus* is a stout plant (2–7 ft.) of low grounds from Newfoundland to Ga. and Ark., variable, and lower forms occurring: very leafy, with numerous crowded heads: lvs. lanceolate to oblong-lanceolate (to 6 in. long), tapering to both ends: involucre short; rays white. A good plant for the wild garden.

L. H. B.

**DIPLOTHÈMIUM** (Greek, double sheathed). *Palmaeæ*, tribe *Coccothææ*. Spineless pinnate palms, low or stemless, or often with ringed, stout, solitary or fascicled trunks.

Leaves terminal, pinnatisect; segms. crowded, lanceolate or ensiform, acuminate, glaucous or silvery beneath, margins recurved at the base, midnerve prominent; rachis 2-faced, strongly laterally compressed; petiole concave above; sheath fibrous, open: spadices erect, long or short-peduncled, strict, thickish; spathes 2, the lower coriaceous, the upper cymbiform, beaked, ventrally dehiscent; bracts short, coriaceous; fls. rather large, cream-colored or yellow, more showy than almost any other palm: fr. ovoid or obovoid, small.—Species 5. Brazil.

*Diplothemium* is a group of very handsome palms. In size the members of this genus seem to vary as much as those included in the *Cocos* group. *D. maritimum*, which is found along the coast of Brazil, is but 10 feet in height when fully developed. This genus is without spines, the leaves being pinnate, very dark green on the upper side and usually covered with white tomentum on the under side, the pinnae being clustered along the midrib in most instances. In a very young plant of this genus the ultimate character is not at all apparent from the fact that the seedling plants have undivided or simple leaves, this characteristic frequently obtaining in the case of *D. caudescens* until the plant is strong enough to produce leaves 4 or 5 feet long or about one and one-half years from germination. Frequently the plant bears both sorts of leaves while young. A warm greenhouse, rich soil and a plentiful supply of water are among the chief requisites for the successful culture of *diplothemiums*. *D. caudescens* is the best known of the genus, and when space may be had for its free development it is one of the handsomest palms in cultivation. See G.C. II. 24:394 for horticultural account of the group.

**caudescens**, Mart. (*Cerôxylon niveum*, Hort.). WAX-PALM. St. 12–20 ft. high, 10–12 in. thick, remotely ringed, often swollen at the middle: lvs. 9–12 ft., short-petioled; segms. 70–90 on each side, ensiform, densely waxy white below, the middle ones 24–28 in. long,  $1\frac{1}{4}$  in. wide, the upper and lower ones shorter and narrower, all obtuse at the apex. Brazil. R.H. 1876, p. 235.

*D. littorale*, Mart. A small graceful palm with finely dissected lvs. and very bright yellow fl.-clusters making it attractive during the spring months. B.M. 4861.—Hardly in cult. in Amer.

JARED G. SMITH.  
N. TAYLOR.†

**DÍPSACUS** (*to thirst*, from the Greek, because the bases of the connate lvs. in some species hold water). *Dipsacaceæ*. TEASEL. Stout tall biennial or perennial herbs of the Old World, two or three of which are weeds; and one of them is cultivated for fuller's teasels.

The plants are prickly or rough-hairy: lvs. opposite, entire, toothed or pinnatifid: fls. small and in dense heads, like those of compositous plants, but the anthers are not united (or syngenesious) as they are in the Compositæ; blue or lilac; involucre-bracts and scales of receptacle sharp or spine-pointed. There are a dozen or more species in Eu., N. Afr. to Abyssinia, and Asia. *D. sylvestris*, Huds., is an intro. weed along roadsides in the northeastern states and Ohio Valley. It is biennial, the st. arising the second year and reaching a height of 5 or 6 ft. It is said to be a good bee plant. Lvs. lance-oblong, toothed and more or less prickly on the margin. The dead stiff stalks of this teasel are conspicuous winter objects in the E. U. S., where it has run wild extensively. *D. laciniatus*, Linn., has been found wild in the U. S.: lvs. pinnatifid or bipinnatifid, ciliate. The fuller's teasel, *D. fullonum*, Linn. (Fig. 1276), is probably derived from the first, and differs from it chiefly in the very strong and hooked floral scales. These scales give the head its value for the teasing or raising the nap on woollen cloth, for which no machinery is so efficient. This plant is grown commercially in a limited area in Cent. N. Y.; see Cyclo. Amer. Agric., Vol. II, p. 636.

L. H. B.

**DIPTERÒNIA** (Greek *dis*, twice and *pteron* wing: the fruit consists of two winged carpels). *Aceraceæ*. Ornamental deciduous tree with handsome large pinnate foliage.

Leaves opposite, petioled, odd-pinnate, with 9-15 serrate lfts.: fls. polygamous, small, in large terminal panicles; sepals 5, longer than the short and broad petals; staminate fls. with usually 8 stamens and a rudimentary ovary in the center; pistillate fls. with a 2-celled compressed ovary; style cylindric with 2 slender recurved stigmas: fr. consisting of 2 1-seeded compressed nutlets connate only at the base and with the wing extending all around.—Two species in Cent. and S. W. China.

The species in cultivation is a small tree with handsome foliage, insignificant flowers, but conspicuous winged fruits in large panicles. It is apparently not hardy North. It grows well in any good soil. Propagation is by seeds.

**sinénsis**, Oliver. Tree, to 30 ft.: lvs.  $\frac{3}{4}$ -1½ ft. long; lfts. 9-15, short-petioled, the upper nearly sessile, the lowest pair sometimes 3-parted, ovate-lanceolate to lanceolate, long-acuminate, coarsely serrate, glabrous or sparingly hairy, 2-4 in. long; panicles loose, 6-12 in. long; fls. whitish, minute, slender-pedicelled: each carpel (samara) of the fr. broadly obovate or nearly orbicular, light brown, about 1 in. long, with the seed near the middle. June; fr. in Sept. Cent. China. J.H. S. 28:60. H.L. 19:1898.

ALFRED REHDER.

**DÍRCA** (*Dirke*, mythological name; also a spring near Thebes). *Thymelæaceæ*. LEATHERWOOD. Two North American small early-blooming shrubs, sometimes planted.

Bushes with tough fibrous bark, alternate, thin short entire petiolate deciduous lvs., apetalous perfect fls. in peduncled fascicles of the previous season's growth, the branches developing subsequently from the same nodes: calyx corolla-like, yellowish, campanulate, undulately obscurely 4-toothed, bearing twice as many exerted stamens as its lobes (usually 8); ovary nearly sessile, free, 1-loculed, with a single hanging ovule; style exerted, filiform: fr. berry-like, oval-oblong. The dircas often have the habit of miniature trees. The bark is of interlaced strong fibers, and branches are so tough and flexible that they may be bent into hoops and thongs without breaking, and were so used by the Indians and early settlers. The leatherwood is not one of the showiest of hardy shrubs, but its small yellowish fls. are abundant enough to make it attractive, and it deserves cult. especially for the earliness of its bloom in spring. It is of slow growth, and when planted singly makes a very shapely specimen; planted in masses or under shade it assumes a straggling habit. It thrives in any moist loam. Prop. by seeds, which are abundant and germinate readily; also by layers.

**palústris**, Linn. LEATHERWOOD. MOOSEWOOD. WICOPY. Fig. 1277. Two to 6 ft. high, with numerous branches having scars which make them appear as if jointed, at the beginning of each annual growth, and with yellow-brown glabrous twigs: lvs. oval or obovate, with obtuse apex, 2-3 in. long, green and smooth above, whitish and downy below, becoming smooth, the base of the petiole covering buds of the next season: fls. yellowish, abundant enough to be attractive, nearly sessile,  $\frac{1}{4}$  in. long, falling as the lvs. expand: fr. hidden by the abundant foliage, egg- or top-shaped,  $\frac{1}{2}$  in. long, reddish, or pale green. Woods and thickets, mostly in wet soil Canada to Fla. and Mo. B.R. 292.—Common.

*D. occidentális*, Gray. A similar species found on northerly slopes of cañons in Calif., differs mainly in the deeper calyx-lobes, lower insertion of the stamens, sessile fls., and white involucre; blooms Nov.-Feb. Not in the trade, but worthy of cult.

A. PHELPS WYMAN.

**DÍSA** (origin of name unknown). *Orchidaceæ*. Terrestrial orchids, mostly South African, of which several are known to fanciers, but only one of which is in the American trade.

Sepals free, spreading, upper one galeate, produced in a horn or spur at the base; petals inconspicuous, small, adnate to the base of the column.—Sixty or more species. *D. grandiflora* is undoubtedly one of the most beautiful of known orchids, but as yet difficult to manage under artificial conditions.

**grandiflora**, Linn. FLOWER OF THE GODS. Root-stock tuberous: sts. 1 ft. or more high, unbranched: lvs. dark green: fls. several; upper sepal hood-like or galeate, 3 in. long, rose-color, with branching crimson veins; lateral sepals slightly shorter, brilliant carmine-red; petals and labellum orange, inconspicuous. S. Afr. B.M. 4073. G.C. II. 18:521; III. 9:365; 33:37. G.M. 54:608. Gt. 59, p. 374. J.H. III. 52:339. O.R. 6:241; 9:273; 20:336.

*D. crassicornis*, Lindl. Spike few-fl'd; lateral sepals oblong, the dorsal smaller; reflexed petals, and lip lan-

1276. Fuller's teasel—*Dipsacus fullonum*. ( $\times \frac{1}{2}$ )

ceolate. S. Afr. Gn. 73, p. 187.—*D. Elwesii*, Hort. A garden hybrid, probably between *D. kewensis* and *D. Veitchii*.—*D. equetris*, Reichb. f. Dorsal sepal funnel-shaped, pale blue; petals white. Rhodesia.—*D. erubescens*, Rendle. Fls. large and handsome, somewhat resembling *D. grandiflora* in color. Trop. Afr.—*D. kewensis*, Hort. Hybrid between *D. grandiflora* and *D. tripetaloides*. Spike few-fl.; fls.  $1\frac{1}{2}$  in. across; lateral sepals rosy pink, the dorsal paler, red-spotted; lip yellowish, crimson-spotted. Gt. 52:1510. O.R. 6:24; 9:273; 20:336.—*D. longicorym*, Linn. f. Plant  $\frac{1}{2}$  ft. high, producing a single fl. about  $\frac{1}{2}$  in. long resembling a light blue delphinium. S. Afr.—*D. lugens*, Bolus. Spike 10–15-fl.; fls. dull purple, the lip green, lacerated. S. Afr. B.M. 8415.—*D. Luna*, Hort. A garden hybrid between *D. racemosa* and *D. Veitchii*.—*D. pulchra*, Sond. Spike 6–12 in. long; fls. rose. S. Afr. G. 28; 201.—*D. racemosa*, Linn. f. Racemes 4–9-fl.; fls. deep rose-red, about  $1\frac{1}{2}$  in. across. S. Afr. B.M. 7021. J.H. III. 47:213.—*D. sagittalis*, Swartz. Fls. in a short raceme, about  $\frac{2}{3}$  in. long, pale lilac, the petals and lip red-streaked. S. Afr. B.M. 7403. G.C. III. 51:312.—*D. Veitchii*, Hort. Hybrid between *D. racemosa* and *D. grandiflora*. Fls. about  $2\frac{1}{2}$  in. across, rose-lilac. J.H. III. 43:145. C.O. 1. O.R. 6:241; 9:273; 20:336.—*D. venusta*, Bolus. A slender species with grass-like lvs. S. Afr.

GEORGE V. NASH.†

**DISANTHUS** (Greek, *dis*, twice, and *anthos*, flower; the fls. being in 2-fl. heads). *Hamamelidaceæ*. Ornamental shrub, grown for its handsome foliage, assuming beautiful autumnal tints.

Deciduous, glabrous: lvs. alternate, long-petioled, entire, palmately veined: fls. perfect, axillary, in pairs on erect peduncles and connate back to back; calyx 5-parted; petals 5, spreading; stamens 5, shorter than sepals; ovary superior, with 2 short styles: fr. a dehiscent caps. with several black glossy seeds in each cell.—One species in Japan. Hardy ornamental shrub of elegant habit, with distinct, handsome foliage, turning to a beautiful claret-red or red and orange in fall. Prop. by seeds, germinating the second or third year, and by layers; possibly also by grafting on *Hamamelis*.

*cercidifolius*, Maxim. Fig. 1278. Shrub, to 10 ft., with slender branches: lvs. roundish-ovate, obtuse or acutish, truncate or cordate at the base, leathery at maturity, dark bluish green above, paler below, 2–4 in. long: fls. dark purple, about  $\frac{3}{4}$  in. across, with linear-lanceolate petals. Oct.: fr. ripens the following Oct. High Mountains of Cent. Japan. G.F. 6:215 (adapted in Fig. 1278). R.H. 1910:363. Demands a light peaty soil.

ALFRED REHDER.

1278. *Disanthus cercidifolius*. ( $\times \frac{1}{2}$ )

The reader now has before him a comprehensive survey of the subject. It is impossible, of course, to list all the plant diseases and all the insect pests in a compilation of this kind; but it is desired that the catalogues shall comprise the most important depredators of the leading horticultural plants. The reader should keep himself informed of the new knowledge and new practice by consulting current publications of the government and the experiment stations.

### Diseases of plants.

Disease in plants may be defined as any derangement or disorganization of the normal structure or physiological functions of the plant, as for example the formation of galls, cankers or distortions, rotting of plant parts, or disturbances in the sap system resulting in wilting, or in the nutritive processes resulting in such symptoms as dwarfing, chlorosis, and the like. Forms of plant diseases are shown in Figs. 1279–1292.

It is often very difficult to distinguish clearly between diseased conditions and abnormalities of other types. Bud-sports, doubling of blossoms, fasciations and many

other similar abnormalities, while often the result of reaction to some pathogen, are not apparently always so and they are often spoken of as teratological phenomena. While the reaction of plants to insect attacks in the formation of galls, cankers, and so on, is to be regarded as symptom of disease, the injuries produced by the mere eating away of parts of leaf, stem or fruit are not usually so to be regarded. Even here, however, it is often difficult to draw a sharp line of demarcation. While disease may

usually be said to result in ultimate injury, there are apparently certain marked exceptions, as in the case of the root tubercles of legumes caused by the attacks of certain nitrogen-fixing parasitic bacteria. Here increased growth and crop-yield are generally held to result.

Diseases of plants are not something new or of recent development, as the grower is often inclined to think. The crops of the husbandman, from the earliest recorded history of his art, have been afflicted with diseases. In the historical writings of the Hebrews, the Bible, and in the writings of the Greeks and Romans, frequent mention is made of such diseases as rusts, smuts and mildews of grain and canker of trees. To be sure, the extensive and intensive crop-cultivation of modern times, together with the extraordinary worldwide transportation and exchange of crop-products, have greatly favored the distribution of plant pathogens (insects, fungi and bacteria), and afford them exceptional opportunities for destructive development. Nor are cultivated plants alone subject to disease. Disease epidemics among weeds and the wild flowers of the woods may be observed any season in localities in which weather conditions especially favor the causal organisms.

The study of the nature and control of plant diseases, however, is of recent development. The first man really to study plant diseases from the true modern economic point of view, that is, with the object of helping the grower to understand and combat or control diseases in his crops, was Julius Kühn. This German, the son of a German land-owner and for many years himself the manager of a large agricultural estate, was the founder of an early German agricultural college. He interested himself, among other phases of agriculture, in plant diseases and their control and his

**DISEASES AND INSECTS.** Under one head it is thought best to bring together the discussions of the so-called enemies of plants,—the parasitic fungi and the depredating insects, together with the means of control. This composite article therefore comprises:

book, "Die Krankheit der Kulturgewächse," published in 1858, is to be regarded as the first book of real economic importance on the subject of diseases in plants. In this remarkable volume is given a concise statement of the thoroughly digested and personally tested knowledge of his time, on the nature and control of plant diseases. He also describes a number of new methods, especially for seed treatment of cereals against smuts, which have become the foundation for many of our present-day practices.

Since Kühn's day there have been remarkable developments in the control of plant diseases. The discovery of bordeaux mixture by the Frenchman Millardet in 1882; the discovery of the formaldehyde treatment of seed for smut by the American plant pathologist, Arthur, in 1896; and the recent development of the use of lime-sulfur solutions and mixtures as a substitute for bordeaux in the spraying of apples and peaches, are but the most noteworthy of the many discoveries and developments in the remarkable growth of this economic science within the last half century.

The economic importance of plant diseases can scarcely be overestimated, as they constitute one of the chief losses in our agricultural resources. The loss from 5 to 25 per cent of many crops from diseases alone each year is so common as to be the general rule. The loss from potato diseases each season in the United States has been carefully estimated at not less than \$36,000,000. Yet, it has been conclusively demonstrated by extensive experiments among potato-growers during a continuous period of ten years, that an annual average increase of over forty bushels per acre may be expected from spraying the crop with bordeaux mixture, from three to five times in the season at a total average cost of about \$5 per acre. The loss from oat-smut commonly averages from 5 to 25 per cent of the crop, yet it may be absolutely prevented by seed treatment at almost insignificant cost. The loss from scab in the apple crop of New York State often totals not less than \$3,000,000 and for the United States a corresponding loss of over \$40,000,000. In 1900, the peach-growers of Georgia lost \$5,000,000 by brown rot, while the average annual loss from the same disease in the entire United States is never less. Yet in each case here mentioned, as well as in most of the other of our common and destructive diseases, cheap and effective means of control are within the reach of every grower.

The value and efficiency of these means have been established beyond doubt. Their profitable application requires only intelligence and practice on the part of the grower.

Symptoms of disease in plants are so varied in character as to make an attempt at wholly satisfactory grouping for practical purposes of doubtful value. Mention of some of the more common types, however, may be useful. The grower must learn by study and experience the more striking symptoms characteristic of those diseases peculiar to the crops that he grows.

Disease may be exhibited in malformations of the leaf, stem, root or fruit, as for example, knots, galls, tubercles, curling,

wrinkling or other distortions. There are such symptoms in crown-gall of trees, black-knot of plums and cherries and leaf-curl of the peach (Fig. 1279). Another type are cankers, dead sunken or roughened areas in the bark of trees or the outer rind of herbaceous

1280. Early blight of potato.

The leaf- or fruit-spot type is also very common. Brown or black spots appear in foliage or fruit. They may be brown dead or rotted areas, or spots due to the growth of the parasite on or under the surface. Bordeaux-injury spots on apple foliage, shot-hole leaf injury of stone fruits, leaf-spot of the currant (Fig. 1281), celery or alfalfa, the tar-spot of the maple, the black-spot of the rose and the apple-scab are of this type. Another not uncommon type is that exhibited in certain bacterial and fungous diseases, where the pathogen infects the sap-true regions of the stems or petioles, resulting in a sudden wilting of leaves and shoots. The wilt diseases of cotton, cucumber, ginseng, watermelon and cowpeas are characterized by this symptom. The yellowing of the foliage, either suffused or localized as spots, rings, and blotches and often accompanied by dwarfing and wrinkling of the affected organs is a common symptom of certain so-called physiological diseases like the peach yellows (Figs. 1282, 1283), little-peach, mosaic disease of tobacco, infectious chlorosis and nitrogen-poisoning of greenhouse cucumbers (Fig. 1284) and other plants.

#### *The causes of disease in plants.*

Etiology, or the cause of disease, has been more generally and carefully investigated than any other phase of the subject, so that we now know much regarding the agents primarily responsible for most plant diseases. These agents may be grouped as follows:

Slime molds, lowly organisms having characters of both plants and animals (see article *Fungi*). The club-root of cabbage, cauliflower and other crucifers, is the best known slime-mold disease.

Bacteria, microscopic unicellular plants which multiply very rapidly by simple fusion (see article *Fungi*). While most species are harmless scavengers of dead organic matter, and a few are known to cause diseases of men and animals, not less than 150 different diseases of plants are now known to be due to the attacks of parasitic bacteria. Some of the commonest bacterial diseases of plants are, fire-blight, crown-gall, olive-knot, soft-rot of vegetables, potato-scab, cucumber-wilt and black-leg of potatoes.

Fungi (see Vol. III) are perhaps responsible for far the greater number of the diseases of plants. They are the causal agents in such well-known diseases as apple-scab, brown-rot of plums and peaches (Fig. 1285), black-rot of grapes, (Fig. 1286) bitter-rot of apples, brown-rot of lemons, late blight of potatoes, peach-

1279. Effects of the leaf-curl fungus on peach foliage. ( $\times \frac{1}{2}$ )

leaf-curl, heart-rot and canker of trees, mildew of many plants, rusts and smuts of cereals (Figs. 1287, 1288, Kansas Experiment Station); in fact the mere enumeration of the more common fungous diseases of plants would fill many columns in this volume.

Algæ, low forms of green plants, most of them living in water or very damp places. Few are known to pro-

1281. Currant foliage attacked by the leaf-spot fungus. ( $\times \frac{1}{2}$ )

duce disease in plants. The red rust of tea is one of the best known algal diseases.

Parasitic angiosperms,—flowering plants, of which there is no inconsiderable number, causing more or less injury to the plants upon which they live. These parasites are usually markedly degenerate in one or more respects, as a result of their parasitism, being often without true roots, or without leaves and frequently without chlorophyll green. As examples we may mention the mistletoes, dodders and broom rapes.

Insects (see page 1034) cause such diseases as galls and similar malformations.

Nematode worms,—minute all but microscopic in size and multiplying rapidly, they constitute one of the greatest crop pests, especially in warm or tropical countries. They usually infest the roots, causing galls or swellings. Some species injure the plants by destroying the fine feeding roots as in the case of the nematode parasites of oats so destructive in certain countries of northern Europe. Over 400 different plants are known to be subject to the nematode root-gall disease. (See pp. 1041-2.)

Physiological disease is a term under which is included all those diseases the cause of which cannot be attributed to some parasitic organism. Their origin is variously attributed to abnormal enzymic activity, disturbed nutrition, and the like. The best-known of these are peach-yellows, chlorosis of the vine, tip-burn (Fig. 1291) mosaic disease of tobacco and leaf-roll disease of potatoes.

The various parasitic organisms cause disease in one of two ways, either by the secretion of toxins and enzymes which at once kill the plant tissues and change them into forms readily available as food for the invader; or the toxins and enzymes secreted merely stimulate or irritate the plant tissues in such a way as to result in abnormal tissue growth or diversion of the food substances of the host to the advantage of the parasite making its home between or in the cells of the host. Both types of disease-production have the same ultimate result, the serious injury or destruction of the infested plant, although the former is usually the more rapid and destructive. Of the first type, rots, blights and leaf-spots are the best examples, and are

characterized by the rapid death and destruction of the affected tissues; of the second type, galls, leaf-curls, rusts and smuts are good examples and are characterized by a rather long period of association of the parasite with the living tissues of its host before marked injury or death of the plant results.

The causal agent is usually associated with the tissues of the host, either the dead or living, during its entire cycle of development. The apple-scab pathogen, *Venturia inæqualis*, will serve admirably to illustrate. It passes the summer on the surface of leaf and fruit. In the autumn when the infested leaves fall to the ground, the fungus, which as a parasite has invaded only the cuticle of the leaf or fruit, now penetrates the dead tissues and develops there during the autumn the winter form of fruit bodies, the minute globose black perithecia, in which during the warm days of early spring the ascospores are rapidly developed. These ascospores (Fig. 1292), eight in a sac, ripen and are discharged by the spring rains that come during the blossoming period. The old leaves on the ground are filled with millions of these minute perithecia with many sacs of ascospores in each perithecium. The spores are shot into the air during the rain and being exceedingly light are carried to the opening leaves and forming fruits, where they germinate, sending out mycelial threads into the cuticle of leaf or fruit forming the characteristic dense dark green or black mats or crusts, the scab-spots. The leaves become crumpled and injured, the young fruits grow one-sided, or if the stem be attacked, soon drop from the tree, thus giving no set of fruit. On the scab-spots the conidia or summer spores cut off from the tips of upright branches in great numbers, are carried by the wind to other leaves and fruits where, with the next rain, they germinate and give rise to new scab-spots and more conidia.

The life-cycle as given for the apple-scab fungus is typical of many of the fungous pathogens of our crops. It must be remembered, however, that each pathogen has habits peculiar to itself; hence the necessity for the most careful study of each that we may know its habits and peculiarities and thus be able successfully to

1282. "Tip growth" of yellows.

Left-hand specimen shows two small-leaved tips appearing in October, two or three of the normal leaves still remaining near the top. The middle specimen shows numerous tips appearing in August. Right-hand specimen is a healthy twig, for comparison.

combat it. The following illustrations will serve to explain and impress this point.

*Plowrightia morbosa*, the fungus causing black-knot of plums and cherries, requires two seasons to complete its life-cycle. The first season there appears on the knots only conidia, followed the second season by a crop of ascospores, produced in perithecia, which form a black crust on the surface where the conidia were earlier produced. Other pathogens like *Exoascus cerasi*, the "witches broom" pathogen of the cherry, lives from year to year as mycelium in the branch and twigs of the broom-like growths it excites, producing each season a crop of spores on the under sides of the leaves. The blister-rust fungus of the white pine, *Cronartium ribicola*, also lives from season to season

1283. The tufted shoots of peach yellows.

in the tissues of the pine, producing each spring a new crop of spores. This pathogen exhibits another habit peculiar chiefly to certain of the rust fungi, namely that it has another stage or spore form on an entirely different host plant, in this case, the currant, especially the European black currant. The apple-rust pathogen, *Gymnosporangium macropus*, exhibits the same habit, passing the winter in galls formed on the twigs of the red cedar. In the spring spores appear on these galls, which germinating in situ give rise to other minute spore bodies, the sporidia. These sporidia are carried by the wind to the young apple leaves and fruit, giving rise there to the rust disease so destructive to certain varieties like the McIntosh and York Imperial. The spores formed on the rusted leaves and fruit of the apple are carried to the cedar, originating a new crop of galls and thus completing the life-cycle.

While some pathogens may develop in both living and dead tissues of their host, as we have seen in the

case of the apple-scab fungus, other pathogens like the rust organism just described or the potato-blight pathogen, *Phytophthora infestans*, require to be constantly associated with the living tissues of their host. The last-mentioned fungus passes the winter as mycelium in the tissues of diseased tubers, grows from thence up through the new shoots, slowly killing them and forming thereon the first crop of conidia, which, carried by the wind to nearby healthy plants, produce the primary infections of the season. The successive crops of conidia produced during the season on the blighted tops are washed into the soil by the rains, and their way to the newly formed tubers, and, infecting them, complete the seasonal cycle of the parasite.

Many fungous pathogens are now known to pass from one generation of the host plant to the next through the seed. The smut parasites of cereals afford remarkable examples of this habit. In the case of the oat-smut fungus, *Ustilago avenae*, the spores ripen as dusty black masses in the panicles of affected plants just as the healthy plants are in blossom. At this time the two hulls inclosing the grain are open. The wind-scattered spores lodge in the open flowers against the young kernel where they are soon safely housed by the closing hulls. They lie dormant along with the ripened seeds until they are planted. Then as the oat kernels germinate, the smut spores do likewise, sending forth their germ tubes which penetrate the young oat sprouts before they emerge from the hull. The mycelium grows along up through the growing oat straw, finally giving rise to the black spore masses in the unfolding panicle. In the case of stinking smut of wheat the seasonal life-cycle of the pathogen, *Tilletia tritici*, is much the same, except that the spores are disseminated at threshing time. Some very important differences in the habits of the loose smut pathogens of wheat, *Ustilago tritici* and of barley, *Ustilago nuda*, have recently been discovered (1902). The spores of these pathogens are also ripened and disseminated at blossoming time, but on falling within the open blossom they germinate at once, sending their germ-tubes into the tender young kernels. The affected kernels are apparently not injured but continue to develop and ripen. The mycelium of the pathogen within remains dormant until the seeds are planted and begin to grow, at which time the mycelium also becomes active. It grows out into the young shoots and up through the lengthening culms eventually to give rise to the black spore masses of the smutted heads. The bean anthracnose fungus, *Colletotrichum lindemuthianum*, is also carried over in the seed. Here the fungus in the black spots or cankers on the pods penetrates into the tender cotyledons of the seed within, goes into a dormant condition as the seed ripens, to become active again when the germinating seed lifts these cotyledons from the soil. A new crop of spores is produced, which, if the season be rainy, are splattered on to the stems and leaves of nearby healthy plants and the pathogen becomes established for another season.

While the wind is the most common disseminating agent of fungus spores, often carrying them for great distances, such agents as rain, flowing water, insects and even man himself, are frequently responsible. It is in the dissemination of bacterial pathogens, however, that insects most generally function. The dreaded fire-blight bacteria are disseminated only by insects or man. They pass the winter in a semi-active state in the half-living tissues along the margins of cankers on limbs or twigs, multiply rapidly with the rise of sap and the heat of spring. They ooze from the affected bark in sticky, milky drops. This ooze is visited by bees and flies, which with besmeared legs and mouthparts fly away to visit the opening apple or pear blossoms. Here they leave some of the bacteria in the nectar where they rapidly multiply, to be more widely distributed by each succeeding visitor. They soon pene-

trate into the tender tissues of the blossom, causing the blossom blight. From these blighted blossoms, sucking insects like the aphids carry the bacteria to the tips of the rapidly growing shoots when in sucking sap they introduce the organisms and twig blight follows. The striped cucumber beetle is probably the chief disseminator of *Bacillus tracheiphilus*, which causes the cucumber-wilt.

#### *Ecological conditions as affecting disease.*

By ecology is meant the influence of such environmental factors as climate, weather, soil and fertilizers, on the disease, its severity, epidemic occurrence, and the like. These factors may influence the severity of the disease by their effect on either the pathogen or the host, or both. For example, most fungous parasites require the presence of water on the host plant in which their spores may germinate, hence severe epidemics of such diseases as potato-blight, apple-scab, brown-rot of stone fruits and black-rot of grapes usually appear in wet seasons. Moreover, the attacking pathogen is especially favored by wet weather at certain seasons or periods in its development, especially the infection period. Continued spring rains about blossoming time favor apple-scab and peach leaf-curl. Late summer rains bring with them epidemics of late blight of potatoes, brown-rot of peaches or late infections of apple-scab. Frequent or continuous rains during June and July in grape regions are usually accompanied by severe attacks of the black-rot pathogen. The relation of rainfall to the pathogen explains why, when there has been a severe epidemic the previous season, the crop may escape if the following season be dry. There is ever a critical period in the development of the pathogen, usually when it is passing from its resting or winter stage to the active vegetative period of the growing season. Moisture and temperature conditions at such periods largely determine whether the disease will be epidemic or not. Of course the necessary abundance of spores to be disseminated is an evident necessity. Favorable weather alone cannot bring on disease as the grower too often believes.

The absence of rains at certain stages in their development is for other pathogens equally essential. The loose smuts of cereals afford good examples. Their spores are powdery and wind-borne and if rains fall when they

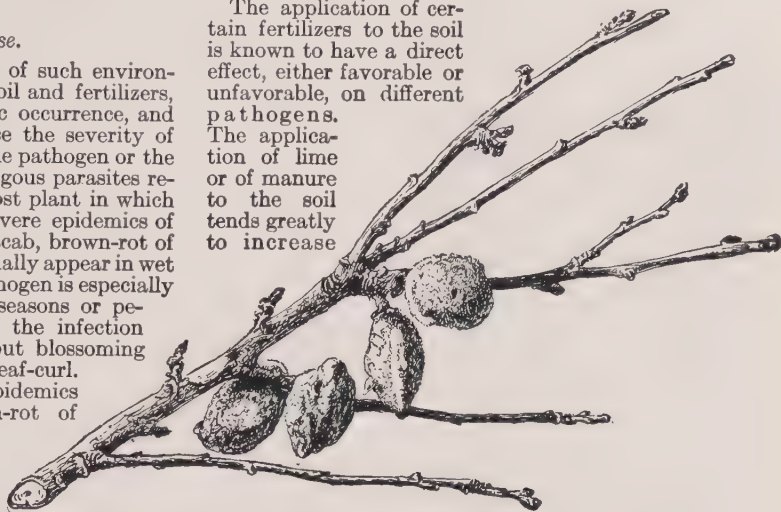

are being disseminated, they are washed to the ground and perish instead of finding their way into the open blossoms of their host. Thus, clear sunny weather during the blossoming period of wheat and oats one season usually means a more or less severe epidemic of smuts the next, while rains at this time, even though there be an abundance of the disease, may mean a clean crop the following year.

1284. Disease of cucumber leaf. The dying margin indicates that the trouble is due to some interference with the food supply. ( $\times \frac{1}{2}$ )

On the other hand, weather conditions may determine the severity or absence of certain diseases by its effect on the host. Long-continued cold rainy weather in the spring, especially following a warm spell, results in a slow succulent growth of the developing peach leaves, rendering them especially susceptible to the attacks of the leaf-curl pathogen.

The application of certain fertilizers to the soil is known to have a direct effect, either favorable or unfavorable, on different pathogens. The application of lime or of manure to the soil tends greatly to increase

1285. Peaches of last year's crop still hanging on the tree, attacked by monilia. The branch is dead from the effects of the fungus. ( $\times \frac{1}{2}$ )

the scab of potatoes planted thereon; while, on the other hand, liming the soil prevents infection of cabbage and cauliflower by the club-root pathogen. Lime likewise favors the development of the root-rot of tobacco and ginseng caused by *Thielavia basicola*, while applications of acid phosphate tend to prevent infection by this pathogen. The effect of fertilizers on the susceptibility of the host has also been shown to be marked in certain cases. Barley, when fertilized with nitrogenous manures, becomes very susceptible to attacks of the mildew *Erysiphe graminis*. Certain varieties of wheat have been observed in Denmark to suffer severely from attacks of the rust *Puccinia glumarum* only when nitrogenous manures are applied. Excessive applications of barnyard manure to greenhouse cucumbers often cause a physiological disease, the symptoms of which are a curling, and dying of the margins of the leaves, accompanied by marked chlorosis or yellowing. Fertilizers or late continued cultivation of pear trees, by lengthening the period of active twig-growth, favor fire-blight, the bacteria of which infect only tender actively growing tissues.

#### *Control of diseases.*

By the term control is meant the profitable reduction of the losses ordinarily sustained from a given disease. The absolute prevention of many plant diseases is either impossible or unprofitable.

There are four fundamental principles upon which all methods of plant-disease control are based, viz.: (1) *exclusion*, (2) *eradication*, (3) *protection* and (4) *immunization*. Upon the first two are based those measures which are directed primarily against the pathogen, upon the last two those which are directed merely toward the protection of the host from pathogens commonly present in the environment. The order in which these principles are here presented represent the logical, though unfortunately not the historical or usual order of their development and application. We will consider briefly under each some of the more important methods now employed for the control of plant diseases.

1. *Exclusion* measures are directed toward keeping disease organisms, usually insects, fungi and bacteria, out of areas, regions or countries in which they do not occur. This is commonly attempted by the passing of laws forbidding the importation of plants affected with

such parasites. As means of enforcing such regulations, some sort of inspection, either at port of entry or at point of destination, is provided. Inspection in the country from which they are exported is also often required. Absolute quarantine against all importation of certain plants from those countries in which dangerous diseases are known to occur is also being practised in some countries, as, for example, prohibit-

ing the importation of potatoes into the United States from those countries in which the black-scab is now known to occur. Exclusion measures, often undertaken when it is too late, are at best under present conditions of doubtful efficiency. Those interested in these methods of control should consult the various pest and disease acts of the different countries of the world. See *Inspection*, in Vol. III.

2. *Eradication*.—On the principle of eradication are based those measures which are directed to the elimination of pathogens already established. While absolute eradication is seldom to be effected, the pathogen may often be eliminated to such an extent as to reduce losses therefrom to a profitable minimum. In Denmark, the destruction of all barberry bushes, the alternate host of the grain-rust fungus, *Puccinia graminis*, has decidedly reduced the severity of this disease in recent years. The careful eradication of all diseased plants is often quite effective even in a small area, like a raspberry or blackberry plantation suffering from the red rust. Here the mycelium of the pathogen lives from year to year in the roots of diseased plants, which each spring send up diseased shoots. On the under side of the leaves of these shoots, the orange-red spores are produced in great abundance, and serve to spread the pathogen to healthy plants. As diseased plants are readily detected in early spring by the pale clustered shoots, they may be removed before spores appear and the pathogen thus eradicated. The black-knot of plums and cherries is most readily and profitably controlled in a similar manner, the knot-affected limbs and twigs being cut out and burned early in the spring before spores appear. The

fire-blight of pears is to be controlled only by systematic eradication, first of all cankers in autumn or early spring, then of all blossom blight as fast as it appears and later of the affected twigs when twig-blight comes on. To be effective, the trees must be inspected two or three times each week throughout the growing season and all diseased parts removed *at once* as soon as discovered.

Another method of eradication especially applicable to seeds, tubers or bulbs, on which spores of the pathogen pass the dormant period, is disinfection. This is accomplished by the application of chemical poisons, either in solution, as powder or as gas, at a strength and for a period of time sufficient to destroy the pathogen without injury to the host. When the pathogen lives over as mycelium in the seed or tuber, the application of heat is sometimes effective. Formaldehyde, as a gas or in solution in water, is now generally employed for the eradication of the smut of oats, the stinking smut of wheat and the potato-scab. (For details of method, see *Formaldehyde*, p. 1028). The spraying of peach trees with copper-sulfate solution, lime-sulfur solution or bordeaux, just before the buds start in the spring, disinfects the trees by destroying the spores of the leaf-curl fungus which pass the winter on the buds.

Pathogens which attack the underground parts of plants may sometimes be eradicated by disinfection of the soil before planting. Drenching the soil with a formaldehyde solution of a strength sufficient to distribute one gallon of the strong 40 per cent solution to each 100 square feet of surface, wetting the soil to a depth of 6 to 8 inches, has been found to be very effective against damping-off, root-rot and similar diseases in forest tree seed-beds, ginseng seed-beds and in the benches in greenhouses. It is also often effective in the eradication of nematodes in greenhouses. Steaming of the soil is also very effective, destroying insects and weed seeds as well as pathogenic fungi. It is not always conveniently applied.

3. *Protection* measures are to be employed in those regions in which the pathogen is very generally and very thoroughly established, or in which for one reason or another eradication is impossible or unprofitable. They aim to protect the crop against attacks of the parasite by means of some external barrier. Spraying is the most commonly employed protective measure. In spraying, the susceptible surfaces of the plant are coated with some slowly soluble poison, known as a fungicide. Fungicides are of various types. They are applied in suspension in water, in solution or dry, *i.e.*, in the form of a fine impalpable powder. The fungicide most generally applied in liquid spraying is bordeaux, a colloidal compound formed by the union of lime-milk and copper-sulfate solution. Minute blue gelatinous

1286. Grapes ruined by black-rot.

1287. Smut of oats.

1288. Loose smut of barley.

membranes are formed which remain for a time suspended in the liquid. When sprayed upon the plants the water soon evaporates, leaving a coating of these dried membranes. The active fungicidal principal in these bordeaux membranes is the copper. When leaves or fruit are rewetted by rains enough of the copper in these membranes comes into solution to prevent the germination of the spores of the parasite that may have been deposited thereon. (See under *Bordeaux*, p. 1028.)

Bordeaux, however, is sometimes injurious to such plants as peaches, plums and apples, and has, within the last few years, been largely replaced as a summer spray, especially for apples. Lime-sulfur, unlike bordeaux, is a solution. It is made by boiling together in water, lime and sulfur. A concentrated solution of certain poly-sulfides of calcium, chiefly penta- and tetrasulfide, is thus obtained which, when properly diluted is applied in the same way as the bordeaux. (For method of preparation, see *Lime-sulfur*, p. 1028). When this solution dries on the leaves and fruit, it is rapidly converted by the action of the atmosphere into other calcium compounds and free sulfur. The sulfur is in a very finely divided state and is the active principal of lime-sulfur. It becomes oxidized in the presence of moisture probably as sulfuric or sulfurous acid, which prevents the germination of the spores of the pathogen. Flowers of sulfur and sulfur-flour, when very finely ground and applied dry by dusting or sprayed on in suspension in water, alone or with lime-milk (the so-called self-boiled lime-sulfur) are also quite effective against certain diseases. Dusting with sulfur is employed in combating powdery mildews of grapes, hops, roses and the rust of asparagus.

Lime-sulfur may not be used on potatoes and grapes, as it dwarfs the plants and reduces the yield, while bordeaux has just the opposite effect on these crops. Bordeaux, as already pointed out, is, however, injurious to leaves and fruit of the apple and to the foliage of peaches and certain varieties of plums. It will thus be seen that there is no universal fungicide and also that both the effect on the host and on the parasite must be considered. It is now known for example that while lime-sulfur is very effective against the apple-scab fungus, it has little fungicidal effect on the spores of the bitter-rot pathogen.

To be effective, fungicides must be applied before the disease appears. As the spores of most parasitic fungi germinate during the period of rainy cloudy weather, the fungicide, to be effective, must be applied *before* and not after such periods. They must not only be thoroughly applied to the susceptible parts but also at the proper stage of growth or development of the plant. To illustrate: the only effective periods for spraying apple trees for scab are: just before the blossoms open (not dormant); just after the petals fall; ten days or two weeks later; and again in late summer just before the late summer rains, to protect the rapidly developing fruit from late infection.

4. *Immunization* consists in establishing within the plant itself some condition which renders it immune or resistant to the attacks of the pathogens. Immune crops may be developed

by selection and propagation of individuals naturally immune, whose immunity has been evidenced by their coming through an epidemic unscathed. Immune varieties may be crossed with susceptible ones having other especially desirable qualities and then by segregation and propagation strains of the crop may be developed combining the resistance or immunity of the one parent with the desirable qualities of the other. Some striking results have been obtained in this line of disease control as witness the wilt-resistant cotton, cowpeas and watermelon, the nematode-free Iron cowpea, rust-resistant wheat, barley, and asparagus, and the anthracnose-resistant clover. Nevertheless, this method of control, while the most ideal, is beset with many difficulties and uncertainties. That pathogens, as well as crops, vary, giving strains capable of attacking host plants immune to other strains of the same pathogen, has generally been overlooked by breeders, and doubtless accounts for the frequent failure of supposedly resistant varieties when transferred to new localities. The production of artificial immunity by the injection of some substance into the plant or by the application of certain substances (fertilizers, etc.) to the soil is at most only in the preliminary stages of experimentation and as yet offers but little of practical value to the grower.

H. H. WHETZEL.

### Fungicides.

A fungicide is any material or substance that kills fungi or their spores. The word is used particularly for those substances employed in the warfare against parasitic fungi.

A satisfactory fungicide must be one that does not injure the plants and at the same time is effective against the parasite. For spraying, additional requirements are imposed: it should not dissolve readily in rain-water; it should adhere to foliage and fruit; in some cases it should be colorless in order not to make ornamentals more unsightly than when diseased. The fungicide which has been used most for general purposes is bordeaux mixture. Lately some other preparations, particularly lime-sulfur combinations, have come into use, and in many cases are supplanting bordeaux. There are in

1290. A blight of grapes due to some constitutional disorder. Notice that the leaves die first at the edges. ( $\times \frac{1}{2}$ )

1289. Strawberry leaf rolled up from the attack of the mildew.

addition a large number of other substances which have fungicidal value and are in more limited use for specific cases. The following directions are taken, with modifications, from the author's part in Bailey's "Farm and Garden Rule-Book."

1291. Tip-burn of potato leaf.—A physiological difficulty or disease, due to some so-called "constitutional" disorder or obstruction (Vermont Experiment Station).

house, where it may be applied (a) through sub-irrigation tile or through specially laid perforated steam pipes in the bottom of the bed. Cover the beds with blankets, introduce steam under pressure of forty to eighty pounds for two hours. Insert thermometers at various places to see that the soil is being uniformly heated. (b) A large galvanized iron tight box may be constructed with finely perforated trays 4 to 6 inches in depth. Soil placed in these trays and steamed for two hours as above will be freed from parasitic organisms. In this case the frames should be sprayed with a solution of formaldehyde, one pint in twelve gallons of water. Steam sterilization of soil may be used on intensively cultivated areas or extensive seed-beds. A portable boiler is necessary. The beds are sterilized after they have been prepared for seed, and just before the seed is sown. A galvanized pan of convenient dimensions and 6 to 8 inches deep is inverted, and the edges are pushed down into the soil 1 or 2 inches. The pan is connected with the steam boiler by means of a steam hose and live steam is run into the pan from twenty to forty minutes under a pressure of eighty pounds and up. The higher the pressure the deeper the soil will be sterilized. The pan must be weighted. Paths should be disinfected by spraying with copper sulfate one pound to fifty gallons of water or with formaldehyde solution one pint to twelve gallons of water. The cost of sterilizing is approximately three-fourths of a cent the square foot. It should be noted that soil-sterilization has an invigorating effect on many plants, and it will be necessary to run green-houses at a lower temperature (5° to 10°) both night and day. Field-sterilization also kills weed seeds, and with the reduction of the cost of weeding makes the process practicable.

#### Substances.

**Bordeaux mixture.**—A bluish green copper compound that settles out when freshly slaked lime and a solution of copper sulfate (blue-stone) are mixed. Many formulas have been recommended and used. The 5-5-50 formula may be regarded as standard. In such a formula the first figure refers to the number of pounds of copper sulfate, the second to the stone or hydrated lime, and the third to the number of gallons of water. Bordeaux must often be used as weak as 2-2-50, on account of injury to some plants.

To make fifty gallons of bordeaux mixture, proceed as follows:

(1) Pulverize five pounds of copper sulfate (blue vitriol), place in a glass, wooden, or brass vessel, and add two or three gallons of hot water. In another vessel slake five pounds of quicklime in a small amount of water. When the copper sulfate is all dissolved, pour into a barrel and add water to make forty or forty-five gallons. Now strain the lime into this, using a sieve fifty meshes to the inch or a piece of cheese-cloth supported by ordinary screening. Stir thoroughly, and add water to the fifty-gallon mark. The flocculent substance which settles is the effective fungicide. Always stir vigorously before filling the sprayer. Never add the strong lime to strong vitriol. Always add a large amount of water to one or the other first. Blue vitriol used alone would not only wash off quickly in a rain, but cause a severe burning of fruit and foliage. Lime is added to neutralize this burning effect of the copper. If the lime were absolutely pure, only slightly more than one pound would be required to neutralize this burning effect. For many purposes an excess of lime is not objectionable and may be desirable.

#### Practices.

**Destroying affected parts.**—It is important that all affected parts should be removed and burned, if possible. In the fall all leaves and fruit that have been attacked by fungi should be raked up and burned. Diseased branches should be severed at some distance below the lowest visible point of attack. Fungous diseases often spread rapidly, and prompt action is usually necessary. Practice clean and tidy culture.

**Rotation of crops.**—This is one of the most effective and practical means of heading off fungous diseases. It is especially applicable to diseases of roots or root-crops, but also to many other diseases of annual plants.

**Sterilizing by steam.**—This is an effective fungicidal practice for several soil-inhabiting organisms which attack roots and stems. This includes nematode worms. It is especially applicable in the green-

For nearly ripe fruit and ornamentals an excess of lime augments spotting. In such cases the least amount of lime possible should be used. Determine this by applying the cyanide test (2).

(2) Secure from the druggist 10 cents' worth of potassium ferrocyanide (yellow prussiate of potash) and dissolve it in water in an eight-ounce bottle. Cut a V-shaped slit in one side of the cork, so that a few drops of the liquid can be obtained. Now proceed as before. Add lime with constant stirring until a drop of the ferrocyanide ceases to give a reddish-brown color.

(3) When bordeaux mixture is desired in large quantities, stock solutions should be made. Place one hundred pounds of copper sulfate in a bag of coffee-sacking, and suspend in the top of a fifty-gallon barrel, and add water to the fifty-gallon mark. In twelve to fifteen hours the vitriol will be dissolved and each gallon of solution will contain two pounds of copper sulfate. Slake a barrel of lime, and store in a tight barrel, keeping it covered with water. Lime so treated will keep all summer. It is really hydrated lime. This is often dried, pulverized, and offered on the market in paper bags of forty pounds each, under such names as ground lime, prepared lime, hydrated lime, and the like. If the paper is not broken, the lime does not air-slake for a long time. One and one-third pounds of hydrated lime equals in value one pound of quicklime. Air-slaked lime cannot be used in preparing bordeaux mixture.

Arsenical poisons can be combined with bordeaux mixture.

**Ammoniacal copper carbonate.**—For use on nearly mature fruit and on ornamentals. Does not discolor. Weigh out three ounces of copper carbonate, and make a thick paste with water in a wooden pail. Measure five pints of strong ammonia (26° Baumé) and dilute with three or four parts of water. Add ammonia to the paste, and stir. This makes a deep blue solution. Add water to make fifty gallons.

**Copper carbonate.**—For use in the above formula, it may be secured as a green powder, or may be prepared as follows: Dissolve twelve pounds of copper sulfate in twelve gallons of water in a barrel. Dissolve fifteen pounds of sal-soda in fifteen gallons of water (preferably hot). Allow the solution to cool; then add the sal-soda solution to the copper-sulfate solution, pouring slowly in order to prevent the mixture from working up and running over. A fine precipitate is formed which will settle to the bottom if allowed to stand over night. Siphon off the clear liquid. Wash the precipitate by adding clear water, stirring, and allowing to settle. Siphon off the clear water, strain the precipitate through muslin, and allow it to dry. This is copper carbonate. The above amounts will make about six pounds.

**Copper sulfate.**—See Sulfate of copper.

**Corrosive sublimate** (mercuric chloride).—Used for disinfecting pruned stubs and cleaned-out cankers, at the rate of one part in 1,000 parts of water. Can be secured from the druggist in tablet form in vials of twenty-five each, and costing 25 cents. One tablet makes a pint of solution. Make and store solution in glass and label "poison."

**Formaldehyde** (40 per cent solution of formaldehyde gas in water).—A pungent, clear liquid, very irritating to eyes and nose. Obtained at any drugstore at about 40 cents a pint. Used for potato-scab, oat smut, bunt in wheat, soil disinfection, and so on.

**Lime.**—Offered for sale in the following forms: (a) Ground rock or ground limestone; air-slaked lime is of the same composition, i.e. a carbonate of calcium. (b) Lump, barrel, stone, or quicklime; this is burned limestone, and should test at least 90 per cent oxide of calcium. (c) Prepared, ground, or hydrated lime; this is water- or steam-slaked quicklime, dried and pulverized. Used as an applicant to the soil to correct acidity, for club-root of cabbage, and for preparing spray mixtures.

**Lime-sulfur.**—In the many possible combinations, lime-sulfur is coming to be equally as important as bordeaux mixture, in the control of many plant diseases.

(1) Flowers of sulfur or very finely powdered sulfur is often dusted on plants for surface mildews.

(2) A paste of equal parts of lime, sulfur, and water. This is painted on the heating-pipes in the greenhouse, and is valuable for keeping off surface mildews.

(3) Home-boiled dilute lime-sulfur. This solution has been widely used in the past as a dormant spray, particularly for San José scale and peach leaf-curl. It is likely to be supplanted by (4) or (5). For preparation see page 1043.

(4) Home-boiled concentrated lime-sulfur. When a great deal of spraying is to be done, a concentrated lime-sulfur

1292. Perithecial of apple scab, showing spores.

solution may be boiled at home and stored in barrels to be used as needed. For method of preparation see page 1043.

Test with a Baumé hydrometer, which has a scale reading from 25° to 35°. Dilutions are reckoned from a standard solution testing 32°. If the solution tests only 28°, it is not so strong as standard, and cannot be diluted so much as a solution testing 32°. The table shows the proper dilution for solutions testing 25° to 35° Baumé:

	1-10	1-15	1-20	1-25	1-30	1-40	1-50	1-60	1-75	1-100
25°	7.4	11	14.7	18.4	22.1	29.5	36.8	44.2	55	73
26°	7.7	11.6	15.4	19.3	23.2	30.9	38.6	46.3	58	77.2
27°	8.1	12.1	16.1	20.2	24.3	32.4	40.5	48.5	60.6	80.7
28°	8.4	12.7	16.9	21.1	25.4	33.8	42.3	50.7	63.5	84.5
29°	8.8	13.2	17.6	22.1	26.5	35.3	44.2	53	66.3	88.2
30°	9.2	13.9	18.4	23	27.6	36.9	46.1	55.3	69	92
31°	9.6	14.4	19.3	24	28.8	38.4	48	58	72	96
32°	10	15	20	25	30	40	50	60	75	100
33°	10.4	15.6	20.8	26	31.2	41.5	52	62.4	78	104
34°	10.8	16.2	21.6	26.8	32.4	43.2	54	64.7	80.8	108
35°	11.2	16.8	22.4	28	33.4	44.9	56	67.4	84.2	112

Decimals are given in all cases, but for practical purposes the nearest even gallon or half gallon can be used, unless appliances for more accurate measurement are at hand. It is understood in making all dilutions that water is added to one gallon of the concentrate to make the stated amount. Do not measure out the stated amount of water and add the concentrated solution to it.

(5) Commercial concentrated lime-sulfur.—As manufactured and placed on the market is a clear amber liquid, and should test 32° to 35° Baumé. It costs about 20 cents a gallon retail, and comes ready to pour into the spray tank. For apple and pear diseases. Arsenate of lead can be used with this solution, and increases its fungicidal value.

(6) Scott's self-boiled lime-sulfur.—This is a mechanical mixture of the two substances, and is really not boiled, the heat being supplied by the slaking lime. In a small barrel or keg place eight pounds of good quicklime. Add water from time to time in just sufficient amounts to prevent burning. As soon as the lime begins to slake well, add slowly (preferably through a sieve) eight pounds of sulfur flour. Stir constantly, and add water as needed. As soon as all bubbling has ceased, check further action by adding a quantity of cold water, or pour into a barrel or tank and make up to fifty gallons. Keep well agitated. Very effective against peach scab and brown rot. Several other formulas have been used: 10-10-50 and 5-5-50. Arsenate of lead can be used with this mixture.

By using boiling water and allowing the hot mixture to stand for half an hour, a stronger spray mixture than the above can be secured. It cannot be used safely on peaches, but has been used successfully on grapes for surface mildew. The addition of sulfate of iron or sulfate of copper, one or two pounds to fifty gallons, has been used for apple rust.

Potassium sulfid (liver of sulfur).—Simple solution, three ounces in ten gallons of water. For mildew in greenhouses, on rose bushes and other ornamentals.

Resin-sal-soda sticker.—Resin, two pounds; sal-soda (crystals), one pound; water, one gallon. Boil until of a clear brown color, i.e. from one to one and a half hours. Cook in an iron kettle in the open. Add this amount to fifty gallons of bordeaux. Useful for onions, cabbage, and other plants to which spray does not adhere well.

Sulfate of copper (blue vitriol).—Dissolve one pound of pure sulfate of copper in twenty-five gallons of water. A specific for peach leaf-curl. Apply once before buds swell in the spring. Cover every bud. For use in preparing bordeaux mixture. Costs from 5 to 7 cents a pound, in quantity.

Sulfate of iron (copperas).—A greenish granular crystalline substance. Dissolve one hundred pounds in fifty gallons of water. For mustard in oats, wheat and the like, apply at the rate of fifty gallons an acre. Also for anthracnose of grapes as a dormant spray.

Sulfur (ground brimstone, sulfur flour, flowers of sulfur).—Should be 99 per cent pure. Valuable for surface mildews. Dust on dry or in the greenhouse used in fumes. Evaporate it over a steady heat, as an oil-stove, until the house is filled with vapor. Do not heat to the burning point, as burning sulfur destroys most plants. To prevent burning, place the sulfur and pan in a larger pan of sand and set the whole upon the oil-stove.

DONALD REDDICK.

### Catalogue of diseases.

**Abies.** WITCHES' BROOM (*Æcidium elatinum*, *Melampsorella elatina*).—On fir causing swellings, cankers, and witches' brooms. Control.—Prune off all affected parts.

**Abutilon.** RUST.—See under *Hollyhock*.

CONTAGIOUS CHLOROSIS.—Variegated leaves.

Control.—Remove variegated leaves and their shoots, keep in dark and remove any further variegated leaves; then the plant should remain green.

**Acacia.** RUSTS (*Æcidium* sp.).—Distorts branches and twigs.

Control.—Prune off diseased parts.

### CATALOGUE OF DISEASES, continued.

**Acer.** TAR-SPOT (*Rhytisma acerinum*).—Black tar-like spots on upper side of the leaves.

Control.—Burn all old leaves in fall or winter.

**SUN SCALD or SCORCH.**—Maples suffer commonly from a drying up of the foliage, due to over-transpiration of water at times when hot winds occur.

**Actinidia.** MILDEW (*Uncinula necator*).—See under *Ampelopsis*.

**Æsculus.** LEAF-SPOT (*Phyllosticta paviae*).—Irregular spots develop rapidly, the larger part of the leaf being involved. Leaves fall prematurely.

Control.—Spray with bordeaux mixture, beginning when the leaves are about half-grown and repeating the process every three weeks.

**Agave.** LEAF-BLOTCH (*Coniothyrium concentricum*).—Grayish, more or less circular dead patches, ranging from ½ to 1 inch in diameter.

Control.—Remove and burn diseased leaves.

**Allium.**—See under *Onion*.

**Almond.** BLIGHT (*Corynyne beyernkii*).—See *Peach Blight*.

YELLOW.—See under *Peach*.

**Alnus.** ROOT-TUBERCLES.—Clumps of small tubercles on the roots. Not important.

WITCHES' BROOMS and BLADDERY DEFORMATIONS OF FLOWERS (*Ezoascus* sp.).—Broom-like tufts of branches and irregular deforming and contortion of fruits.

Control.—See under *Peach Leaf-Curl*.

**Alyssum.** MILDEW (*Erysiphe polygoni*).—See under *Verbena*. Disease very similar.

**Amarantus.** WHITE "RUST" or MILDEW (*Albugo bliti*).—See similar disease under *Radish*.

**Amelanchier.** RUST (*Gymnosporangium* sp.).—Orange rust spots on leaves.

Control.—Keep junipers at a considerable distance.

WITCHES' BROOM (*Dimerosporium collinsii*).—Thick twisted broom-like growth of branches.

Control.—Cut out the brooms.

**Ampelopsis.** BLACK-ROT.—See under *Grape*.

MILDEW (*Uncinula necator*).—Powdery mildew growths on upper side of leaf.

Control.—Dust with sulfur.

**Anemone.** ROOT-DECAY (*Sclerotinia tuberosa*).—Rhizomes decayed and large lumps form on the outside.

Control.—Eradicate affected rhizomes and the cup-like fungous bodies near such plants.

RUST.—Several rusts attack species of *Anemone*.

**Anthurium.** BLIGHT (*Glomerella cincta*).—See under *Orchids*.

**Apple.** BLIGHT.—The same disease as *Pear Blight*, which see.

CANKER.—Smooth cankers in bark of trunk or limbs usually indicate blight (*Bacillus amylovorus*); rough ones, New York apple-tree canker (*Sphaeropsis malorum*), or the nail-head canker (*Numularia discreta*).

Control.—As soon as noticed, cut away dead bark and wood to the living tissue and paint over with lead paint or coal-tar. SCAB (*Venturia inaequalis*).—Olive-green, brownish or blackish scab-like spots on leaves and fruit.

Control.—Rake and burn or plow under old leaves very early in spring. Spray with lime-sulfur 32° Baumé, 1-40, or bordeaux, 3-3-50: (1) when blossom buds show pink; (2) when majority of petals have fallen; (3) three weeks after 2, depending upon the weather; (4) if a late attack is feared, spray before fall rains begin.

**Apricot.** YELLOW.—See under *Peach*.

BLACK-SPOT or SCAB.—See under *Peach*.

**Aquilegia.** MILDEW (*Erysiphe polygoni*).—See under *Verbena*. Disease very similar.

BLACK-SPOT (*Bacillus delphini*).—Sunken black spots on leaves and stems.

Control.—Remove and burn diseased parts.

**Artemisia.** RUST (*Puccinia asteris*).—Same rust as on *Asters*, which see.

**Artichoke.** SOFT-ROT.—See under *Carrot*.

**Arum.** LEAF-SPOT (*Protomyces ari*).—Irregular bleached patches on leaves and leaf-stalks of *A. maculatum*.

Control.—Burn diseased plants.

**Asparagus.** RUST (*Puccinia asparagi*).—A rust of the tops which is often so severe as to kill them, thus interfering with root-development.

Control.—Dust with flowers of sulfur about every three weeks while dew is still on in the morning. Use dusting machines.

**Aspidistra.** LEAF-BLOTCH (*Ascochyta aspidistræ*).—Large, irregular, bleached spots with black streaks running across.

Control.—Remove diseased leaves.

**Aster.** RUST (*Puccinia asteris*).—Brown rust of leaves.

Control.—Eradicate the affected leaves.

**Aucuba.** FREEZING.—Young leaves suffer from spring frosts.

**Auricula.** LEAF-BLOTCH (*Heterosporium auriculi*).—Three or four olive-green spots on each leaf. Spots become brown and fall out.

Control.—Do not have excessive moisture. Spray with potassium sulfid and ventilate well.

**Avocado, or Persea.** ANTHRACNOSE (*Colletotrichum gloeosporioides*).—See under *Pomelo*.

## CATALOGUE OF DISEASES, continued.

- Bamboo.** SMUT (*Ustilago shiriana*).—Internodes and tips of young shoots attacked. Wild and cultivated bamboo attacked in Japan.  
*Control.*—Bordeaux mixture and sprinkling soil with lime before the shoots appear.
- Banana.** ROT (*Bacillus musæ*).—Leaf-blades droop, turn yellow; petioles decay, letting leaves drop, and finally whole plant rots to the ground.  
*Control.*—Practise sanitation.
- Bean.** ANTHRACNOSE, or POD-SPOT (*Colletotrichum lindemuthianum*).—Reddish brown, scab-like spots on stems, pods, and veins of leaves, particularly on yellow-podded snap beans. Fungus enters the beans.  
*Control.*—Use seed only from pods without spots. Spray plants, from beneath and above, every ten days.  
 BLIGHT (*Bacterium phaseoli*).—Large papery spots on leaves and watery spots on pods.  
*Control.*—As for Anthracnose.
- Beet.** HEART-ROT (*Phoma betæ*).—Leaves appear spotted late in July, then wilt, and finally a dry heart-rot appears.  
*Control.*—Destroy affected plants. Practise long rotations. Treat seed with formalin, one pint in thirty gallons of water.  
 SCAB.—The same disease as *Potato Scab*, which see.
- Begonia.** ROOT-ROT (*Thielavia basicola*).—See under *Nicotiana*.
- Berberis.** RUST (*Puccinia graminis*).—Orange-colored rust spots on under side of leaf.
- Betula.** LEAF-SPOT (*Glaeosporium betularum*).—Round spots with blackish margin.  
 HEART-ROT (*Fomes ignarius*).—See under *Fagus*.
- Blackberry.** CROWN-GALL, or ROOT-GALL (*Bacterium tumefaciens*).—Swellings, hard or soft, on roots and stem below ground.  
*Treatment.*—Plow up and burn all bushes in a diseased patch. Plant clean roots in a new place.  
 ANTHRACNOSE.—See under *Raspberry*.  
 RED or ORANGE RUST.—See under *Raspberry*.  
 LEAF-SPOT.—See under *Deuberry*. Same disease.
- Blueberry.** RUST (*Calyptospora goeppertiana*).—Stem attacked, swollen, spongy, at first pink, changing to brown and blackish. Plants taller than healthy and leaves dwarfed.  
*Control.*—Segregate from species of fir and spruce.
- Brassica.** See under *Cabbage*.
- Brussels Sprouts.** CLUB-ROOT.—See under *Cabbage*.
- Buxus.** STEM-BLIGHT (*Nectria rousseliana*).—Twigs killed, reddish pustules appearing on stems and leaves.  
*Control.*—Remove all diseased parts and burn.
- Cabbage.** CLUB-ROOT, or CLUB-FOOT (*Plasmodiophora brassicæ*).—A contorted swelling of roots and sickly wilted tops.  
*Control.*—Destroy affected seedlings. Lime the soil at least eighteen months before planting cabbage, using at the rate of two tons of quicklime to the acre.  
 BLACK-ROT (*Bacillus campestris*).—Sap-tubes in leaves and stem turn black and the leaves drop, thus preventing heading.  
*Control.*—Practise crop-rotation. Soak the seed for fifteen minutes in a solution of mercuric chloride, one tablet in a pint of water.
- Cactus.** SPOT (*Diplodia opuntiae*).—Sometimes a serious disease.
- Calathea.** LEAF-BLIGHT (*Cephaleurus parasiticus*).—The epidermal cells contain the alga, which spreads over the leaf, blackening and killing it.  
*Control.*—Remove diseased leaves.
- Calceolaria.** LEAF-BLIGHT (Ascribed to a *Micrococcus*).—Brownish patches on lower leaves, many times bordered by the small veins of the leaf.  
*Control.*—Burn affected plants.
- Campanula.** RUST (*Coleosporium campanulæ*).—Red and brown rust spots on leaves.  
*Control.*—Segregate from *Pinus rigida*.
- Capsicum.** ANTHRACNOSE.—Same as on *Piper*, which see.
- Carnation.** RUST (*Uromyces caryophyllinus*).—Brown, powdery pustules on stems and leaves.  
*Control.*—Spray once in two weeks with a solution of copper sulfate, one pound to twenty gallons of water. Pick off diseased leaves. Keep temperature low.
- Carpinus.** BLACK-MOLD (*Dimerosporium pulchrum*).—On leaves.  
*Control.*—Spray with any good fungicide.  
 HEART-ROT (*Fomes fulvus*).—Red-brown decay; crumbles when crushed.  
*Control.*—Surgery methods.
- Carrot.** SOFT-ROT (*Bacillus carotovorus*).—A soft-rotting of the root identical with the soft rots of other root crops.  
*Control.*—Good drainage of soil. Steam sterilization of soil.  
 LEAF-SPOT or EARLY LEAF-BLIGHT (*Cercospora apii*).—See under *Celery*.
- Carya.**—See under *Hickory-Nut*.
- Castanea.**—See under *Chestnut*.
- Catalpa.** LEAF-BLIGHT.—Sudden blackening and dying of leaves in early summer.  
 HEART-ROT (*Polystictus versicolor*).—Heart-wood becomes straw-colored and finally soft.  
*Control.*—Surgery.  
 ROOT-ROT of seedlings (*Thielavia basicola*).—See under *Nicotiana*.
- Cauliflower.**—See under *Cabbage*.

## CATALOGUE OF DISEASES, continued.

- Celastrus.** MILDEW (*Phyllactinia coryleæ*).—Powdery mildew of leaves.  
*Control.*—Dust with sulfur.
- Celery.** EARLY LEAF-BLIGHT (*Cercospora apii*).—A spotting and eventual blighting of leaves.  
*Control.*—Spray with ammoniacal copper carbonate, 5-3-50, beginning in seed-bed and keeping new growth covered throughout the season.  
 LATE BLIGHT (*Septoria petroselinii* var. *apii*).—Blight of foliage appearing late in season and in storage.  
*Control.*—As above. Grow under half shade.
- Celtis.** MILDEW (*Peronosporium celidis*).—Definite spots on veins, water-soaked dark green becoming gray.  
*Control.*—Spray with bordeaux mixture.
- Cercis.** LEAF-SPOT (*Ascochyta pisi*).—Spots round, yellowish with brown margin on leaves and stem.  
*Control.*—Spray with dilute bordeaux mixture on first appearance.
- Chamaecyparis.** TWIG DISEASE (*Pestalotia funerea*).—Bark of young branches killed, needles die.  
*Control.*—Prune off affected parts and clean up litter and burn.
- Chard (Beta).** HEART-ROT (*Steccherinum ballonii*).—Kills tops of trees.  
 LEAF-SPOT (*Cercospora beticola*).—Brown, purplish bordered spots on leaves.  
*Control.*—Pick off and destroy diseased leaves.
- Cherry.** BROWN-ROT (*Sclerotinia fructigena*).—The flowers decay, the leaves become discolored with irregular brown spots, and the fruit rots on the tree.  
*Control.*—Spray with bordeaux mixture, 4-4-50, or lime-sulfur, 1-40 (1) just before the blossom buds open; (2) just after the blossoms fall; (3) one or two more applications at intervals of ten days.  
 POWDERY MILDEW (*Podospheera oxycanthæ*).—Leaves and twigs affected, often causing defoliation.  
*Control.*—Spray with lime-sulfur, 1-40, or dust heavily with powdered sulfur.
- Black-Knot.**—See under *Plum*. Same disease.
- Chestnut.** CANKER, or BARK DISEASE (*Endothia parasitica*).—Sunken or swollen cankers on limbs or trunk. Limbs die and leaves and buds cling in winter.  
*Control.*—Remove diseased parts and burn. Paint all wounds. Little chance of saving trees in infested locality.
- Chicory.** STEM-SPOT (*Pleospora albicans*).—Yellowish-gray spots on lower portion of the stem. Later on smaller branches and leaves. Plant destroyed.  
*Control.*—Eradicate diseased plants.
- Chrysanthemum.** LEAF-SPOT (*Septoria chrysanthemi*).—Small dark brown spots, which increase in size until leaf is killed.  
*Control.*—Pick and burn affected leaves. Spray with bordeaux mixture, 4-4-50.  
 RUST (*Puccinia chrysanthemi*).—Reddish brown rust pustules on leaves.  
*Control.*—As for *Leaf-Spot*.
- Cineraria.** MILDEW (*Bremia lactucae*).—Plants stunted and of a pale color, finally wilting. Same disease on lettuce.  
*Control.*—Remove diseased plants. Do not use same soil again.  
 RUST.—See under *Senecio*.
- Citrus.**—See under *Orange*, *Lemon*, *Grapefruit*, etc. The "wither tip" disease described under *Pomelo* is common to species of citrus.
- Clematis.** LEAF-SPOT (*Cylindrosporium clematidis* var. *jackmanii*).—Causing loss of lower leaves at times. Not serious.
- Cocoanut.** BUD-ROT (*Bacillus coli*).—Rot of soft tissues of cocoanut plant and is perhaps responsible for cocoanut bud-rot.  
*Control.*—Not given.
- Coffea.** LEAF-DISEASE (*Hemileia vastatrix* and *H. woodii*).—Circular discolored areas, turning pale yellow and becoming studded with orange-yellow spots.  
*Control.*—Burn all diseased leaves.
- Colchicum.** RUST (*Uromyces colchici*).—Black spots on leaves. Looks like a smut disease.  
*Control.*—Diseased leaves should be burned.
- Colocasia.** ROOT-ROT (*Peronospora trichomata*).—Sap-tubes turn yellow and finally entire tuber becomes black.  
*Control.*—Dry tubers thoroughly before storing. Do not plant in soil in which the disease has occurred.
- Convolvulus.** MILDEW (*Albugo ipomæe-panduræ*).—Distortions and white or yellow blisters.  
*Control.*—Remove diseased plants and spray with bordeaux mixture frequently.
- Cordyline.** BLIGHT.—See under *Orchids*.
- Coreopsis.** MILDEW (*Sphaerotheca humuli* var. *fuliginea*).—Powdery mildew of the leaves.  
*Control.*—Dust with sulfur.
- Corn.** SMUT (*Ustilago zeæ*).—Boils on stalks, ears or tassels, at first white, then black, and, when burst open, containing black powder, the spores.  
*Control.*—Cut out developing smut-boils and burn.  
 WILT (*Pseudomonas Stewartii*).—Sap-tubes turn yellow and plant wilts and dries up.  
*Control.*—Burn affected plants. Grow varieties not affected

## CATALOGUE OF DISEASES, continued.

- Cornus.** TWIG-BLIGHT (*Diaporthe albocanis*).—Twigs die, bark turns yellow and is covered with numerous small pimples.  
Control.—Prune off and destroy affected parts.
- Corylus.**—See under *Filbert*.
- Cosmos.** STEM-BLIGHT (*Phomopsis stewartii*).—Brown spots rapidly enlarging on stems of mature plants. Parts above wilt and die.  
Control.—Difficult and no certain methods known. Remove diseased stems and burn.
- Cotoneaster.** RUST (*Gymnosporangium clavariæforme*).—Orange rust pustules on leaves.  
Control.—Keep at a distance from junipers.
- Cranberry.** BLAST, or SCALD (*Guignardia vaccinii*).—Young flower and fruits blasted, older fruits appear scalded or watery.  
Control.—Spray five or six times with bordeaux mixture, 5-5-50, to which has been added four pounds of resin fish-oil soap. Begin just before the blossoms open.
- Cratægus.** RUST (*Gymnosporangium* sp.).—Orange rust pustules on leaves and petioles.  
Control.—Keep at a distance from junipers.
- Cress.** WHITE MOLD.—See under *Horse-Radish*.
- Crocus.** ROOT-ROT (*Rhizoctonia* sp.).—Important in France and likely occurring here.  
Control.—Sanitation, new soil frequently or soil sterilization.
- Cucumber.** BLIGHT, or MILDEW (*Pseudoperonospora cubensis*).—A blighting and premature yellowing of the leaves.  
Control.—Spray with bordeaux mixture, 5-5-50, every ten to fourteen days after plants begin to run.
- WILT.**—See under *Cucurbita*.
- Cucurbita.** WILT (*Bacillus tracheiphilus*).—Sap-tubes are clogged and destroyed, causing the plant to wilt.  
Control.—Eradicate the striped beetle. Gather and destroy all wilted leaves and plants.
- Cupressus.** ROOT-ROT.—See under *Pine*. Same disease.
- Twig Disease.**—See under *Chamæcyparis*.
- Witches' Broom** (*Gymnosporangium ellisii*).—Fasciation of branches.  
Control.—Prune off affected parts.
- Current.** WILT, or CANE-BLIGHT (*Botryosphæria ribis*).—Canes die suddenly, the leaves wilting.  
Control.—No satisfactory method known. Cut out and burn affected plants.
- Rust** (*Cronartium ribicola*).—Brown rust pustules and brown felt-like growth on under side of leaf. Black currants especially susceptible.  
Control.—Grow at least 500 feet from white pine trees.
- Cycas.** LEAF-SPOT (*Mycosphaerella tulasnei*=*Cladosporium herbarum*).—Gray spots and final death of leaves.  
Control.—Remove and burn affected parts.
- Cyclamen.** LEAF-SPOT (*Glomerella rufomaculans* var. *cyclaminis*).—Spots circular, slightly water-logged, with sharply defined outlines.  
Control.—Destroy affected leaves by burning.
- BLIGHT.**—Similar to *Lilium Leaf-Spot*, which see.
- Dahlia.** WILT (*Sclerotinia sclerotiorum*).—White mold on stem, later yellowing and wilting of plant, and finally stem collapses.  
Control.—Remove and burn affected plants. Green stable manure favors the disease.
- Daphne.** LEAF-SPOT (*Mycosphaerella laureola*).—Similar to *Strawberry Leaf-Spot*, which see.
- Date.** See under *Palms*.
- Delphinium.** BLACK-SPOT (*Bacillus delphini*).—Sunken black spots on stem and leaves.  
Control.—Remove and burn diseased parts.
- Dewberry.** LEAF-SPOT (*Septoria rubi*).—Small pale spots of dead leaf-tissue finally becoming dotted with black specks.  
Control.—No successful method of treatment is known.
- Dianthus.**—See under *Carnation*.
- Digitalis.** MILDEW (*Peronospora sordida*).—Broadly effused, dingy lilac patches of mildew on under surface of leaves.  
Control.—Spray with bordeaux mixture.
- Diospyros.** MILDEW (*Podosphaera ozyacanthæ*).—Powdery mildew of the leaves.  
Control.—Dust with sulfur.
- Dracæna.** BLIGHT.—See under *Orchids*.
- Eggplant.** ANTHRACNOSE (*Gloeosporium melongenæ*).—Spots on fruit. Same as on *Piper*, which see.
- STEM ROT** (*Nectria ipomææ*).—Spreading spots on the stem.  
Control.—Spray mixtures may be of avail.
- Elæagnus.** ROOT-TUBERCLES.—See under *Alnus*. Not destructive.
- Endive.** RUST (*Puccinia endiviæ*).—Rust spots on leaves.  
STEM-ROT.—See under *Chicory*.
- Eucalyptus.** TUMOR (*Ustilago vriesiana*).—Woody tumors at collar of tree. Production of black soot-like mass of spores between wood and bark.  
Control.—Surgery methods.
- Euphorbia.** BLIGHT (*Gloeosporium euphorbiæ*).—Causes death of floral portion just before flowering time and the parts below are soon blighted.  
Control.—Burn affected plants. Spray with bordeaux mixture.

## CATALOGUE OF DISEASES, continued.

- Fagus.** HEART-ROT (*Fomes ignarius*).—White, dry, and somewhat solid decay of heart-wood bordered by fine black lines.  
Control.—See under *Arboriculture, Diseases of Trees*.
- Ferns.** TIP BLIGHT (*Phyllosticta pteridis*).—Brown spots at or near tips of the fronds covered with minute black dots.  
Control.—Remove and burn the blighted leaves and then spray with bordeaux mixture.
- Ficus.** LEAF-SPOT (*Leptostromella elastica*).—Causes spots on leaves. See also under *Fig*.
- Fig.** LEAF-SPOT (*Cercospora bolleana*).—Brown spots on leaves. Leaves turn yellow and drop off.  
Control.—Spray with bordeaux mixture while leaves are young.
- Filbert.** BLACK-KNOT (*Cryptosporella anomala*).—Serious stem disease, canker girdles the stems and kills parts above.  
Control.—Prune off affected parts and burn.
- Forsythia.** LEAF-SPOT (*Alternaria forsythiæ*).—Forms sub-circular spots.  
Control.—Spray with bordeaux mixture.
- Fraxinus.** RUST (*Puccinia fraxinata*).—Swellings of midribs of leaves and petioles with orange rust spots on them.  
Control.—Keep the common grass *Spartina cynosuroides* away from the trees.
- Freesia.** LEAF-SPOT and WILT (*Heterosporium gracile*).—Large brown spots with darker margin, numerous; soon the leaves wilt and die.  
Control.—Spray with ammoniacal copper sulfate.
- Galanthus.** DECAY (*Sclerotinia galanthi*).—In place of the flower a shapeless mass is produced covered with brown mildew. Tubers decay also.  
Control.—Remove all affected parts and burn. Use new soil thereafter.
- Gardenia.** RUST.—See under *Coffea*. Same disease.
- Genista.** ROOT-TUBERCLES.—Beneficial.
- Gentiana.** RUST (*Puccinia gentianæ*).—Lower leaves first attacked, become yellow and die. Disease gradually works upward.  
Control.—Destroy affected plants.
- Geranium.** MILDEW (*Plasmopara geranii*).—Downy mildew of leaves.  
Control.—Spray with bordeaux mixture.
- Gladiolus.** SMUT (*Urocystis gladioli*).—Black smut pustules on corms.  
Control.—Destroy affected corms. Use new soil.
- Gleditsia.** LEAF-SPOT (*Leptostroma hypophylla*).—Leaflets become covered with small black specks, causing some of them to turn yellow and fall.
- Gooseberry.** MILDEW (*Sphaerotheca mors-uvæ*).—A powdery mildew of the fruit and young growth of English varieties.  
Control.—Spray with potassium sulfid, one ounce to two gallons of water, at intervals after leaves begin to unfold.
- Grape.** BLACK-ROT (*Guignardia bidwellii*).—Brown circular spots on leaves, black, elongated, sunken pits on petioles, canes, etc., and on the berry a brown rot with shriveling and wrinkling.  
Control.—Spray with bordeaux mixture, 4-4-50, before rains. Spray (1) when the third or fourth leaf unfolds; (2) as soon as the blossoms have fallen; (3) when berries are size of a pea; (4) about two weeks later. Two more applications if wet season.
- Downy Mildew, or Leaf-Blight** (*Plasmopara viticola*).—White frost-like patches on under side of the leaf.  
Control.—Same as *Black-Rot*.
- Grapefruit.** LEAF-SPOT (*Pestalotzia guépini*).—Large spots with dark margins. Leaves fall prematurely. On other species of *Citrus* also.  
Control.—Destroy affected leaves.
- Guava.** ANTHRACNOSE (*Glomerella psidii*).—Circular brown, decayed areas on fruit. Like apple bitter-rot.  
Control.—None given.
- Hedera.** LEAF-SPOT and LEAF BLIGHT (*Vermicularia trichella*).—Rapid blackening of the etiolated portion of the leaf.  
Control.—Remove and burn affected leaves and spray with bordeaux mixture.
- Helianthus.** RUST (*Puccinia helianthi*).—Red rust pustules on leaves of most species of *Helianthus*.  
Control.—No specific control measures worked out.
- Helleborus.** LEAF-BLOTCH (*Coniothyrium hellebori*).—Large circular brownish blotches of scorched appearance, covered with minute black dots.  
Control.—Cut off and burn affected leaves.
- Hemerocallis.** LEAF-SPOT.—See under *Freesia*.
- Hibiscus.** LEAF-SPOT (*Phyllosticta idæcola*).—Indistinct brown spots with whitish centers.  
Control.—Burn affected leaves.
- MILDEW** (*Microsphaera euphorbiæ*).—Powdery mildew of leaves.  
Control.—Dust with sulfur.
- Hickory-nut.** LEAF-SPOT (*Marsonia juglandis*).—Large leaf-spot, causing premature dying of leaves.  
Control.—Spraying with bordeaux mixture may be of value.

## CATALOGUE OF DISEASES, continued.

- Hollyhock.** RUST (*Puccinia malvacearum*).—All parts of plant show reddish brown pustules.  
Control.—Eradicate mallow. Pick off diseased leaves and burn. Spray every week with bordeaux mixture, 4-3-50.
- Horse-Radish.** WHITE MOLD (*Cystopus candidus*).—Deforming and swelling of leaves and stems, with white powdery surface growth.  
Control.—Hardly important enough on the radish to necessitate control.
- Hyacinthus.** BLIGHT (*Pseudomonas hyacinthi*).—Serious pest in the Netherlands. Sap-tubes filled with yellow slime.  
Control.—Destroy all affected plants.
- Hydrangea.** LEAF-BLIGHT (*Phyllosticta hydrangeæ*).—Leaf-spot disease which becomes serious at times.  
Control.—Destroy diseased leaves as soon as noticed.
- Iberis.** CLUB-ROOT.—See under *Cabbage*.
- Impatiens.** MILDEW (*Plasmopara obducens*).—Downy mildew of the leaves.  
Control.—Remove affected leaves and spray with bordeaux mixture.
- Ipomœa.** RUST (*Coleosporium ipomœæ*).—Common rust spotting of leaves.  
Control.—Destroy affected leaves.  
MILDEW.—See under *Convolvulus*.
- Iris.** LEAF-BLIGHT (*Botrytis galanthina*).—First the leaves and flowers are much distorted and covered with black mold growth; later the bulb may be destroyed.  
Control.—Eradicate diseased plants and grow in new soil.
- Juglans.** LEAF-SPOT (*Gnomonia leptostyla*).—Brown leaf-spot, causing defoliation.  
Control.—Collect and burn fallen leaves. Spray with bordeaux mixture while leaves are young.
- Juniperus.** CEDAR APPLES (*Gymnosporangium spp.*).—Large or small red and woody growth at tips of branches. Gelatinous in wet weather.  
Control.—Prune off affected parts. Keep apples, pears, and hawthorns at a distance.
- Kale.** BLACK-ROT.—See under *Cabbage*.
- Kohlrabi.** CLUB-ROOT.—See under *Cabbage*.
- Laburnum.** LEAF-SPOT (*Peronospora cystisi*).—Leaves become brown-spotted. Seedlings killed.  
Control.—Spray with bordeaux mixture.  
CONTAGIOUS CHLOROSIS.—See under *Abutilon*.
- Larix.** CANKER (*Dasyctypha willkomi*).—Canker of trunk and branches, usually around base of trunk.  
Control.—Eradicate diseased parts, using tree surgery methods.
- Laurus.** WITCHES' BROOM (*Exobasidium lauri*).—Branched out growths, antler-like, 2 or 3 feet in length, springing from the leaves.  
Control.—Prune off affected parts.
- Lemon.** BROWN-ROT (*Pythiacystis citrophthora*).—White mold on surface of fruit.  
Control.—Not destructive in orchard. Add copper sulfate to water when washing lemons to prevent infection of healthy ones.  
LEAF-DISEASES.—Not well understood. Probably controllable by spraying.
- Lespedeza.** MILDEW (*Microsphaera diffusa*).—Powdery mildew of leaves.  
Control.—Dust with sulfur.
- Lettuce.** DROP, or ROT (*Sclerotinia libertiana*).—Base of stems or leaves rots off, allowing leaves to drop.  
Control.—Sterilize soil with steam before planting.  
MILDEW.—See under *Cineraria*.
- Ligustrum.** ANTHRACNOSE (*Glaeosporium cingulatum*).—Affected areas light brown either oblong on one side of the stem or completely girdling it.  
Control.—Destroy by burning affected plants.
- Lilium.** LEAF-SPOT (*Botrytis sp.*).—Orange-brown or buff blotches on leaves, stem and flowers of *L. candidum*. May be same as *Tulipa* Mold, which see.  
Control.—Eradicate diseased plants.
- Lily-of-the-Valley.** STEM-ROT.—See under *Pæonia*.
- Liriodendron.** TWIG BLIGHT (*Myxosporium longisporium*).—Killing twigs.  
Control.—Prune off diseased twigs.
- Lobelia.** CANKER (*Phoma devastatrix*).—Portions of the stems covered with minute black dots.  
Control.—Remove diseased plants. They never bloom.
- Lonicera.** CANKER (*Nectria cinnabarina*).—Rough canker on limbs covered with flesh-colored or red bodies.  
Control.—Prune off or cut out all affected parts and cover wounds with tar.
- Lupinus.**—See under *Pea*.
- Lychnis.** SMUT (*Ustilago violacea*).—Pollen-sacs filled with black dust which escapes and discolors the flower.  
Control.—Destroy the affected plants and use new soil.
- Lycopersicum.**—See under *Tomato*.
- Magnolia.** LEAF-SPOT.—See under *Grapefruit*.
- Malva.** RUST.—See under *Hollyhock*. Same disease.

## CATALOGUE OF DISEASES, continued.

- Mangifera.** BLACK BLIGHT (*Dimerosporium mangiferum*).—Intense black velvety patches on both surfaces of the leaves.  
Control.—Spray with any good spray mixture.
- Matthiola.** CLUB-ROOT.—See under *Cabbage*.
- Mentha.** RUST (*Puccinia menthæ*).—A most destructive rust disease.  
Control.—None given.
- Mignonette.** LEAF-SPOT (*Cercospora resedæ*).—First reddish discoloration of leaves. Later small depressed spots with brownish or yellowish margin.  
Control.—Spraying with bordeaux mixture gives good results.
- Morus.** LEAF-SPOT (*Cercospora moricola*).—Not serious.  
LEAF-BLIGHT (*Pseudomonas mori*).—Wilt and death of leaves. Cankers girdle the twigs.  
Control.—Prune off diseased parts and burn.
- Muscari.** SMUT (*Urocystis colchici*).—Long black powdery streaks on leaves.  
Control.—Destroy affected plants by burning. Use new soil.
- Mushroom.** MOLD (*Mycogone perniciosa*).—Mushrooms develop abnormally as monstrous soft growths. These develop into a moldy mass and rot.  
Control.—Affected beds should be thoroughly cleaned and sprayed with copper sulfate, one pound to fifty gallons of water.
- Muskmelon.** DOWNY MILDEW.—See under *Cucumber*.  
WILT.—See under *Cucurbita*.
- Narcissus.** LEAF-SPOT (*Ramularia narcissi*).—Spots on leaves and stem.  
Control.—Burn diseased parts and spray with bordeaux mixture.
- Nasturtium.** WHITE "RUST." (*Cystopus candidus*).—See under *Horse-Radish*.
- Nectarine.** YELLOWS, etc.—See under *Peach*.
- Nerium.** BLACK MOLD (*Capnodium fædum*).—Black velvety-like growth on leaves.  
Control.—Spray with bordeaux mixture.
- Nicotiana.** ROOT-ROT (*Thielavia basicola*).—Blackening and rotting of the roots of seedling plants.  
Control.—Steam sterilization of seed-beds.
- MOsaic or CALICO DISEASE.**—Enzymic disease. Mottling of leaf. Spread by touch.
- Oak.** ANTHRACNOSE (*Gnomonia veneta*).—Brown spotting on under side of leaves, along veins. Brown pustules on spots. Death of leaves and twigs. See under *Arboriculture, Diseases of Trees*.  
Control.—Collect and burn all diseased twigs and leaves. Spray with bordeaux mixture frequently from time buds swell.
- Oenothera.** LEAF-GALLS (*Synchytrium fulgens*).—Yellow swellings on the leaves.  
Control.—Destroy affected leaves.
- Okra.**—See under *Hibiscus*.
- Olive.** LIMB-GALL, or KNOT (*Pseudomonas oleæ*).—Knots or galls on the twigs and limbs.  
Control.—Remove and burn affected limbs.
- Onion.** MILDEW (*Peronospora schleideniana*).—Causes a wilt or blight of the leaves.  
Control.—Spray with bordeaux mixture, 5-5-50, to which has been added one gallon of resin sal-soda sticker. First application when third leaf has developed, repeating every ten days until harvest time.  
SMUT (*Urocystis cepulæ*).—Black pustules on leaves and bulbs. Seedlings may be killed outright.  
Control.—Grow seed in new soil. Drill in with the seed one hundred pounds of sulfur and fifty pounds of air-slaked lime to the acre.
- Opuntia.** SPOT (*Diplodia opuntia*).—Sometimes a serious pest of cactus.
- Orach.** GALLS (*Urophylctis pulposa*).—Glassy swellings on leaves, stems and flowers of *Chenopodium* and *Atriplex*.  
Control.—Burn affected plants.
- Orange.** BLACK-MOLD (*Capnodium citri*).—Black mold-like growth on leaves and fruit.  
Control.—Spray with any good fungicide.
- Orchids.** LEAF-BLIGHT (*Glomerella cincta*).—Leaf dies back from the tip, turning brown.  
Control.—Burn affected leaves. Spray frequently then with bordeaux mixture.
- Ornithogalum.** WARTS (*Synchytrium niesii*).—Dirty white warts on leaves, bounded by a dark line.  
Control.—Burn diseased leaves.
- Pæonia.** STEM-ROT and WILT (*Sclerotinia pæonia*).—Gradual wilting and dying of leaves caused by decay of stem at or near surface of soil.  
Control.—Spray the stems frequently with a strong fungicide. Burn affected plants.
- Palms.** LEAF-SPOT (*Glaeosporium allescheri*).—May cause ultimate death of leaves.  
Control.—Frequent spraying with bordeaux mixture and eradication of diseased leaves may prove beneficial.

## CATALOGUE OF DISEASES, continued.

- Pandanus.** BLACK CANKER (*Nectria pandani*).—Kills branches and entire plants. Black pustules on bark oozing black tendrils.  
*Control.*—Cut out diseased portions as soon as noticed.
- Pansy.** LEAF-SPOT (*Peronospora viola*).—Discolored spots with pale violet growth on them.  
*Control.*—Spray with bordeaux mixture.
- Papaver.** MILDEW (*Peronospora arborescens*).—Downy mildew of wild and cultivated poppies. Especially injurious to seedlings of garden species.  
*Control.*—Spray with bordeaux mixture.
- Parsley.** LEAF-SCORCH (*Septoria petroselinii*).—Small scattered brown patches, which increase in size until whole leaf is covered.  
*Control.*—Spray early with dilute bordeaux. Pick off and burn affected leaves.
- Parsnip.** LEAF-BLIGHT.—See under *Celery*, *Early Leaf-Blight*.
- Pea.** MILDEW (*Erysiphe polygoni*).—A powdery mildew on pods and leaves.  
*Control.*—Dust sulfur over the plants.
- Peach.** BLIGHT (*Coryneum beyerinkii*).—A spotting, gumming and death of the buds and twigs, particularly in the lower parts of the tree. The fruit drops.  
*Control.*—For California conditions, two applications bordeaux mixture, 5-5-50, or lime-sulfur, 1-10, (1) in November or December, and (2) in February or March.
- LEAF-CURL** (*Eozosus deformans*).—Leaves curl and wrinkle.  
*Control.*—Spray with lime-sulfur, 1-11, before buds swell.
- BROWN-ROT** (*Sclerotinia fructigena*).—Rot on fruit and cankers on limbs.  
*Control.*—Spray with self-boiled lime-sulfur, 8-8-50, adding two pounds arsenate of lead. Spray (1) about time shucks are shedding from young fruit; (2) two or three weeks later; (3) one month before fruit ripens.
- SCAB, or BLACK-SPOT** (*Cladosporium carpophilum*).—Black scab-like spots on fruit.  
*Control.*—Self-boiled lime-sulfur applied as under *Brown-Rot*.
- YELLOW.**—A fatal disease. Red spots in fruit. Tuft-like growth of new shoots and finally yellow foliage.  
*Control.*—Burn affected trees.
- Pear.** BLIGHT (*Bacillus amylovorus*).—Flowers, young fruit, twigs, and leaves turn black and die. Limbs die back and sunken cankers form in bark.  
*Control.*—Eradicate all wild hawthorns, pears and apples. Inspect and remove all blighted parts of tree. Paint wounds with coal-tar.
- SCAB.**—Very similar disease to *Apple Scab*, which see.
- Pecan.** LEAF-BLOTCH (*Mycosphaerella convexula*).—Dark-colored blotches covered with minute black dots on leaves in mid-summer.  
*Control.*—None given.
- Pelargonium.** DROPSY.—Translucent spotting of leaf. Spots finally die.  
*Control.*—Withhold water until absolutely necessary.
- Persimmon.** ANTHRACNOSE (*Glomerella rufomaculans*).—Similar if not identical to *Piper Anthracnose*, which see.
- Petunia.** WILT.—See under *Dahlia*.
- Phlox.** STEM-CANKER (*Pyrenochaeta phloxidis*).—Canker just above the ground on the stem. Plant dies; first turning yellow and then falls over.  
*Control.*—Diseased stems should be removed and burned.
- Physalis.** WILT (*Bacillus solanacearum*).—Pith of stem turns brown, sap-tubes filled with viscid ooze.  
*Control.*—Get rid of insects such as potato beetle and burn all affected plants.
- Picea.** LEAF-SPOT and LEAF-CAST (*Phoma sp.*).—Causes discoloration and dropping of needles. Black dots on affected needles.  
*Control.*—Clean up all fallen needles and burn.
- DROUGHT INJURY.**—Drying up of needles. Water in dry weather.
- Pine.** ROOT-ROT (*Armillaria mellea*).—Tops turn yellow and die, swelling of trunk at surface of ground. Decay of roots with black threads abundantly present. Toadstools around base of tree.  
*Control.*—Dig up and burn and destroy all toadstools near the affected trees.
- Pineapple.** HEART-ROT.—Browning of the axis of the fruit, due to excessive moisture at time of ripening.  
*Control.*—Keep down humidity in greenhouses.
- Piper.** ANTHRACNOSE (*Glосporium piperatum*).—Spots on leaves of plants. Also apple bitter-rot fungus (*Glomerella rufomaculans*) causes similar spots on the fruits.  
*Control.*—Frequent spraying with bordeaux mixture.
- Platanus.** ANTHRACNOSE.—See under *Oak*. Same disease.
- Plum.** BLACK-KNOT (*Plowrightia morbosa*).—Black tumorous swellings from 1 to several inches in length, on limbs and twigs.  
*Control.*—Burn all affected parts in the fall. Burn whole tree if badly affected.
- BROWN-ROT.**—See under *Peach*.
- Polygonum.** TAR-SPOT (*Rhytisma bistortæ*).—Black tar-like spots on leaves.  
*Control.*—Burn affected leaves.
- Pomegranate.** INTERNAL ROT (*Sterigmatocystis castanea*).—Central cavity of fruit occupied by a black sporulating fungus.  
*Control.*—None known.

## CATALOGUE OF DISEASES, continued.

- Pomelo.** WITHER-TIP (*Colletotrichum gloeosporioides*).—Anthracnose cankers of stem, spots on leaves and flowers and general wilting of tips of branches.  
*Control.*—Prune off affected parts and spray with bordeaux mixture.
- Populus.** HEART-ROT (*Polyporus sulphureus*).—Red rot of the wood, which finally breaks up into cubes.  
*Control.*—Surgery methods.
- Potato.** EARLY BLIGHT (*Alternaria solani*).—Circular spots, usually in July and final blighting of whole leaf.  
*Control.*—Spray with bordeaux mixture, every ten days, beginning when plants are 6 to 8 inches high.
- LATE BLIGHT and POTATO-ROT** (*Phytophthora infestans*).—Quick-spreading watery appearing spots in leaves. Mildew on under side. Plants appear as scalded by hot water. Tubers rot in soil or soon after digging.  
*Control.*—Spray with bordeaux mixture, 5-5-50, at least three applications and in wet seasons, six or more may be necessary. Use from forty to one hundred gallons per acre.
- SCAB** (*Oöspora scabies*).—A scabby and pitted roughness of the tubers.  
*Control.*—Keep lime and ashes off the land. Soak uncut seed tubers in a solution of formalin, one pint to thirty gallons of water for two hours. Avoid land that has grown scabby potatoes.
- Potentilla.** LEAF-SPOT.—See under *Strawberry*.
- Primula.** ROT (*Botrytis sp.*).—Similar to rot of *Pæonia*, which see.
- Prune.**—See under *Plum*.
- Prunus.**—See under *Cherry*, *Plum* and *Peach*.
- Pseudotsuga.** BLIGHT (*Sclerotinia fockeliana*).—Gray mold of seedlings and younger shoots of older trees in moist situations.  
*Control.*—Spray with bordeaux mixture.
- Psidium.**—See under *Guava*.
- Pyrus.**—See under *Apple* and *Pear*.
- Quince.** BLIGHT.—See under *Pear*.
- RUST** (*Gymnosporangium globosum*).—Orange rust of fruit.  
*Control.*—Destroy red cedars in the neighborhood, also wild apples and hawthorns. Spray as for *Apple Scab*.
- Radish.** WHITE "RUST" or MILDEW (*Albugo candidus*).—A whitish powdery growth on the leaves and petioles, often causing distortion.  
*Control.*—Steam sterilize the soil before planting.
- CLUB-ROOT.**—See under *Cabbage*.
- BLACK-ROT.**—See under *Cabbage*.
- Ranunculus.** MILDEW (*Plasmopara pygmaea*).—Downy mildew of leaves.  
*Control.*—Spray with bordeaux mixture.
- Raspberry.** ANTHRACNOSE (*Glосporium venetum*).—Circular or elliptical, gray scab-like spots on the canes.  
*Control.*—Remove diseased canes as soon as fruit is picked. Avoid taking young plants from diseased plantings.
- CROWN-GALL.**—See under *Blackberry*.
- RED, or ORANGE RUST** (*Gymnosporangium interstitialis*).—Dense red powdery growth on under side of leaves of black varieties and blackberries.  
*Control.*—Dig up and destroy affected plants.
- LEAF-SPOT.**—See under *Dewberry*. Same disease.
- Retinospora.** GALL (*Gymnosporangium sp.*).—Swellings on limbs and twigs with red-brown pustules covering them.  
*Control.*—Prune off affected parts and keep at a distance from species of *Pomæ*.
- Rhamnus.** RUST (*Puccinia coronata*).—Irregular yellow blotches, with yellow pustules on under side of leaf. Also on fruit and flowers.  
*Control.*—Keep at a distance from "rusted" cereals and other grasses.
- Rheum.** SOFT-ROT.—See under *Carrot*.
- Rhododendron.** GALLS (*Exobasidium rhododendri*).—Galls of the size of a pea or larger, at first pale green, then red and brownish covered with white bloom.  
*Control.*—Leaves bearing galls should be removed and burned.
- Rhubarb.** SOFT-ROT.—See under *Carrot*.
- Rhus.** CANKER and TWIG BLIGHT (*Endothia parasitica*).—See under *Chestnut*. Causes death of twigs.
- Ribes.**—See under *Currant* and *Gooseberry*.
- Richardia.** SOFT-ROT (*Bacillus arbores*).—Soft rotting of corms (bulbs) and leaves.  
*Control.*—Change soil every three or four years. Reject corms which show the disease.
- Robinia.** HEART-ROT (*Trametes robinophila* and *Fomes rimosus*).—Heart-wood converted into punk. Shelf-like bodies grow from wounds.  
*Control.*—Surgery methods.
- Rose.** MILDEW (*Sphaerotheca vannosa*).—A white powdery mildew on new growth.  
*Control.*—In greenhouses, keep steam-pipes painted with a paste of equal parts lime and sulfur mixed in water. Out-of-doors roses should be dusted with sulfur flower or sprayed with potassium sulfid, one ounce to three gallons of water.
- STEM-BLIGHT.**—Similar to *Raspberry Anthracnose*, which see.

## CATALOGUE OF DISEASES, continued.

- Rubus.**—See under *Raspberry*.
- Salix.** RUST.—Numerous species of the rust fungi produce red rust spots on the leaves.  
Control.—Keep at a distance from species of conifers.
- HEART-ROT** (*Trametes suaveolens*).—Enters through wounds.  
Control.—Surgery methods.
- Salsify.** MILDEW (*Albugo tragopogonis*).—Distortion and white blisters on host.  
Control.—Eradicate affected plants and grow on new soil apart from wild and cultivated species of the Compositæ.
- Sambucus.** CANKERS.—See under *Lonicera*.
- Sarracenia.** BLIGHT.—See under *Orchids*.
- Saxifraga.** RUST (*Puccinia pascchkei* and *P. saxifrage*).—Dark brown concentric circles of rust pustules on upper surface of the leaves.  
Control.—Burn affected leaves.
- Scilla.** BULB-ROT (*Sclerotinia bulborum*).—Yellow stripes and blotches on leaves in early summer, with olive-brown mold on them. Rots the bulb later.  
Control.—Destroy affected plants. Spray with potassium sulfid. Use new soil thereafter.
- Sedum.** LEAF-SPOT (*Septoria sedi*).—Dark circular blotches appear on the leaves and defoliation occurs.  
Control.—Destroy affected parts by burning.
- Sempervivum.** RUST (*Endophyllum sempervivi*).—Brown rust pustules rupturing epidermis of leaf.  
Control.—Destroy affected plants as the fungus lives over from year to year in the same plant.
- Senecio.** RUST (*Coleosporium senecionis*).—Orange patches on under surface of leaf.  
Control.—Keep at a distance from species of *Pinus*. Burn affected plants to protect neighboring pines.
- Sequoia.** BLIGHT.—See under *Pseudotsuga*.
- Silene.** SMUT.—See under *Lychnis*.
- Solanum.**—See under *Potato*, *Eggplant*, etc.
- Sorbus.** BLIGHT.—See under *Pear*.
- Spinach.** ANTHRACNOSE (*Colletotrichum spinaceæ*).—Spots on leaves, at first minute and watery, gradually increasing in size and becoming gray and dry.  
Control.—Gather and destroy all diseased leaves.
- MILDEW (*Peronospora effusa*).—Gray, slightly violet, patches of a velvety texture on under side of leaves.  
Control.—As for Anthracnose, which see.
- Spiræa.** RUST (*Triphragmium ulmaricæ*).—Reddish yellow and dark brown rust pustules on leaves.  
Control.—Burn affected parts.
- Squash.** WILT.—See under *Cucurbita*.
- Strawberry.** LEAF-SPOT, or LEAF-BLIGHT (*Mycosphærella fragariæ*).—Small purple or red spots appearing on leaves. Leaf appears blotched.  
Control.—Spray with bordeaux mixture, 4-4-50, soon after growth begins and make three or four additional sprayings during season.
- Sweet Pea.** MILDEW.—See under *Pea*.
- Sweet Potato.** BLACK-ROT (*Ceratocystis fimbriata*).—Black shank and a black rot of tuber.  
Control.—Never use sprouts from affected potatoes. Steam sterilize hotbeds.
- ROTS.—The sweet potato is susceptible to a large number of rots, soft, dry, hard, white, etc.  
Control.—Use soil which has not grown diseased sweet potatoes heretofore.
- Syringa.** MILDEW (*Microsphaera alni*).—White powdery mildew on upper surface of leaves.  
Control.—Dust with sulfur.
- TWIG AND BUD DISEASE (*Phytophthora syringæ*).—Tips of twigs killed.  
Control.—Prune off twigs.
- Thalictrum.** RED-SPOT (*Synchytrium anemones*).—Red eruptions on stem, leaf and flower. Causing at times swelling and crumpling of the organ.  
Control.—Burn affected parts.
- Thuja.** ROOT-ROT (*Polyporus schweinitzii*).—Diseased wood yellowish, cheesy, brittle when dry.
- HEART-ROT (*Fomes carneus*).—Causes pockets in the affected wood.  
Control.—Remove all affected wood, using surgery methods.
- Tilia.** LEAF-SPOT (*Cercospora microsora*).—Causes spotting and defoliation.  
Control.—Two sprayings in Massachusetts resulted in longer retention of the leaves.
- Tomato.** LEAF-SPOT (*Septoria lycopersica*).—At first small spots appear, which spread until the whole leaf is consumed. Fruit may be attacked.  
Control.—Spray with bordeaux mixture, 4-4-50, making the first application two weeks after the plants are set out and repeating every two weeks throughout the season.
- DOWNY MILDEW.—See under *Potato*. Late Blight.
- END-ROT.—Due to lack of sufficient soil moisture.  
Control.—Water soil in dry periods.
- Toxylon** (*Maclura*). RUST (*Physopella ficæ*).—Pale cinnamon-brown rust pustules on under side of leaf.  
Control.—Destroy by burning the affected leaves.

## CATALOGUE OF DISEASES, continued.

- Tropæolum.**—See under *Horse-Radish*.
- Tsuga.** HEART-ROT (*Trametes pini*).—Light brown decay pitted with small oblong cavities, which are white-lined.
- SAP-ROT (*Fomes pinicola*).—Soft decay of sap-wood.  
Control.—Surgery methods.
- Tulipa.** MOLD (*Sclerotinia parasitica*).—Olive-brown, velvety patches formed on leaves, stem, and flowers; also, later, small black lumps at base of stems.  
Control.—Burn affected plants.
- Turnip.** CLUB-ROOT.—See under *Cabbage*. Same disease.
- SOFT-ROT.—See under *Carrot*. Same disease.
- Ulmus.** TAR-SPOT (*Gnomonia ulmea*).—Black spots on upper surface of leaves.  
Control.—Burn old leaves in fall or winter.
- HEART-ROT (*Pleurotus ulmaris*).—Soft rotting of wood.  
Control.—Surgery methods.
- Vaccinium.** LEAF-BLISTER (*Exobasidium vaccinii*).—Large blisters on leaves, petioles and stems, of a red or purple color. White bloom beneath.  
Control.—Remove and burn diseased parts.
- Verbena.** MILDEW (*Erysiphe cichoracearum* and others).—Powdery mildew growths on leaves.  
Control.—Spray with any good fungicide or dust with powdered sulfur.
- Veronica.** LEAF-SPOT (*Septoria veronicæ*).—Well-defined spots on leaves.  
Control.—Pick off and burn affected leaves.
- Vinca.** LEAF-SPOT (*Sphæropsis vincæ*).—Leaves disfigured by spots which occur on the stem at times as well.  
Control.—Destroy diseased parts of plants.
- Violet.** ROOT-ROT (*Thielavia basicola*).—Plants make poor growth; roots rotted off.  
Control.—Start in steam-sterilized soil, and transfer to sterilized beds.
- Vitis.**—See under *Grape*.
- Walnut.** BLIGHT (*Pseudomonas juglandis*).—Black spotting of fruit and black cankers on the stems. Twigs and fruit-spurs killed.  
Control.—None known except such as mentioned under *Pear Blight*. Grow immune varieties.
- ANTHRACNOSE, or LEAF-BLIGHT (*Marsonia juglandis*).—See under *Hickory-Nut*. Same disease.
- Watermelon.** MILDEW.—See under *Cucumber*.
- WILT (*Fusarium vasinfecta*).—Wilting of leaves and plant dries up.  
Control.—None recommended. Resistant varieties should be grown.
- Yucca.** LEAF-BLOTCH.—See under *Agave*.
- Zea.**—See under *Corn*.
- Zinnia.** WILT.—See under *Dahlia*.

DONALD REDDICK.

## Insect enemies of plants.

The animals which constitute the insect world play an important part in most horticultural operations. The busy bee is an indispensable aid in the production of many fruits, but the equally busy jaws of canker-worms or other insects oftentimes seriously interfere with man's plans for profitable crops. Horticulturists should become more intimately acquainted with their little friends and foes in the insect world. Not only from the economic standpoint is this knowledge necessary in the business of growing plants, but the striking peculiarities of form, coloring, structure, habits, and the wonderful transformations of insects afford one of the most interesting fields in nature. The life-stories of many insects, if told in detail, would rival in variety and interest many a famous fairy tale. The science that treats of insects, or entomology, has now reached the stage at which its devotees are no longer looked upon with ridicule in most communities. At the present time more than 350 trained men are officially employed in entomological work in the United States and Canada.

*What they are.*—An insect is an animal which, in the adult stage, has its body divided into three distinct regions: the head, the thorax and the abdomen (Fig. 1293). The head bears one pair of antennæ, and there are always three pairs of legs and usually either one or two pairs of wings attached to the thorax. By these characteristics one can usually readily distinguish an adult insect from any other animal. Among the near relatives of insects in the animal world are the cray-

fish, sow-bugs, and crabs, but these are mostly aquatic animals, breathing by true gills; they have two pairs of antennæ, and at least five pairs of legs. Centipedes, or "hundred-legged worms," and millipedes, or "thousand-legged worms," are also nearly related to insects, but they have the thorax and abdomen forming a continuous region, and with six to 200 segments, each bearing one or two pairs of legs; they have one pair of antennæ.

1293. A beetle, showing the different parts.

*How they are constructed.*—Insects are constructed on an entirely different plan from the higher animals. Their supporting skeleton is outside, it being simply the skin hardened more or less by a horny substance, known as chitin. This firm outer wall, or skeleton, supports and protects the muscles, blood-vessels, nerves, and other organs within. The mouth-parts, antennæ and eyes of an insect are attached to its head, and all are exceedingly useful organs, as will be shown later in discussing the feeling and the other sensations of an insect. An insect's wings and legs are always borne by the thorax. The wings are primarily organs of flight, but are used as musical organs by some of the grasshoppers and crickets. Female canker-worm moths, bed-bugs, and some other insects have practically no wings, and the house-flies, mosquitos, male bark lice, and similar insects have but one pair of wings. Insects use their legs primarily for locomotion; some have their front legs modified for catching other insects for food; others have hind legs fitted for jumping, while the honey-bee has little "pockets" on its hind legs for carrying pollen to feed its young.

The arrangement of the internal organs in insects is interesting and somewhat peculiar. The alimentary or food canal in larvæ is a nearly straight tube, occupying the central portion of the body; in adult insects it is usually much longer than the body and is more or less folded; from the mouth the food passes through a

pharynx, an esophagus, sometimes a crop and a gizzard, a stomach, and a small and large intestine. The nervous system of an insect is similar to that in the higher animals, but it extends along the venter instead of the back. There is a little brain in the upper part of the head, and two nerve cords extend from this around the food-canal to another ganglion or nerve center in the lower part of the head; two nerve cords then extend longitudinally along the venter and connect a series of nerve centers or ganglia, typically one for each segment of the body.

1294.

Head of grasshopper.

Showing the great eye. A detail of a part of the surface of the compound eye is also shown.

From each of these ganglia or little brains nerves arise, which supply the adjacent organs and ramify throughout the body. In insects, all parts of the body cavity that are not occupied by the internal organs are filled with a rich, colorless or slightly greenish blood. There is no system of tubes like our arteries and veins, in which the blood is con-

fined and through which it flows. There is a so-called "heart" above the food-canal, along the middle line of the back; it is a tube consisting of several chambers communicating with each other and with the body cavity by valvular openings. The blood is forced through this heart into the head, where it escapes into the body cavity. It then flows to all parts of the body, even out into the appendages, in regular streams which have definite directions, but which are not confined in tubes. They, like the ocean currents, are definite streams with liquid shores. Insects do not breathe through the mouth, as many suppose, but through a series of holes along the sides of the body. These openings, or spiracles, lead into a system of air-tubes, called tracheæ. These tracheæ branch and finally ramify all through the insect. Insects have no lungs, but the tracheæ sometimes connect with air-sacs or bladders in the body, which help to buoy up the insect when flying. Thus the relation between the circulation of the blood and respiration is not nearly so intimate in insects as in man. In insects the air is carried to all the tissues of the body in the tracheæ and the blood simply bathes these tissues. Just how the blood is purified and how the waste matter is disposed of in insects are not yet clearly understood. Aquatic insects breathe by either carrying down bubbles of air from the surface entangled under their wings, or they may be provided with organs known as tracheal gills; these

1295. Fossil dragon-fly, *Petalia longialata*. ( $\times \frac{1}{4}$ )

are usually plate-like expansions of the body that are abundantly supplied with tracheæ, in which the air is brought practically in contact with the air in water, and may thus be purified. More than 4,000 different muscles have been found in a single caterpillar. Notwithstanding their delicate appearance, these muscles are really very strong and their rapidity of action is wonderful; in certain gnats the muscles move or vibrate the wings 15,000 times a second.

*Their sensations.*—Insects can see, feel, hear, taste and smell, and they may also possess other senses, as a sense of direction. Many insects have two kinds of eyes. On each side of the head the large compound eye is easily recognized (Fig. 1294); each compound eye is composed of many small eyes, from fifty in some ants to many thousands in a butterfly or dragon-fly. Between these compound eyes, from one to four simple eyes are to be found in many adult insects. Caterpillars and other larvæ possess only simple eyes. It is thought that each facet of the compound eye sees a part of an object; thus the whole eye would form a mosaic picture on the insect's brain. The simple eyes doubtless see as our eyes do, and seem to be best adapted for use in dark places and for near vision. Insects do not see the form of objects distinctly, but their eyes are doubtless superior to ours in distinguishing the smallest movements of an object. It is now supposed that no insects can distinctly see objects at a greater distance than 6 feet. It must be a sixth

sense, a sense of direction, which enables the bee to find its way for a mile or more back to its home. Insects are doubtless able to distinguish the color of objects, and some insects seem to prefer certain colors. Blue is said to be the favorite color of the honey-bee, and violet that of ants; ants are also apparently sensitive to the ultra-violet rays of light, which man cannot perceive. It is generally supposed that the shape and high colors of flowers attract insects; but recent experiments seem to show that insects are guided to flowers by the sense of smell rather than by sight. The hard outer

skin of an insect has no nerves distributed in it, hence it is not sensitive; but it is pierced with holes, in which grow hairs that are in connection with nerves at their base. It is by means of these sensory hairs that insects feel, and are sensitive to touch on most parts of the body. Doubtless insects are not deaf, for we know that many of them make sounds, and it must naturally follow that they have ears to hear, for there is every reason to suppose that they make these sounds as love-songs to attract the

of each front leg. Some think that mosquitos have the faculty of the perception of the direction of sound more highly developed than in any other class of animals. Insects undoubtedly possess the sense of taste. When morphine or strychnine was mixed with honey, ants perceived the fraud the moment they began to feed. The substitution of alum for sugar was soon detected by wasps. Bees and wasps seem to have a more delicate

gustatory sense than flies. Taste organs have been found in many insects, and are usually situated either in the mouth or on the organs immediately surrounding it.

Many experiments have shown that the antennæ are the principal organs of smell in insects. Blow-flies and cockroaches which have had their antennæ removed are not attracted by their favorite food, and male insects find their mates with difficulty when deprived of their antennæ. The familiar world which surrounds us may be a totally different place to insects. To them it may be full of music which we cannot hear, of color which we cannot see, of sensations which we cannot perceive. Do insects think or reason? Why not? Their actions are said to be the result of inherited habit or instinct. But some of them have been seen to do things which require the exercise of instinctive powers so acute and so closely akin to reason that one can hardly escape the conclusion that some insects are endowed with reasoning powers.

*Their number, size and age.*—Experts guess that there are from 2,000,000 to 10,000,000 different kinds of insects in the world. Only about 400,000 of these have yet been described and named by man. Between 30,000 and 40,000 are now known in North America. Four-fifths of all the kinds of animals are insects; some single families of insects are said to contain more species than one can see stars in a clear sky at night; and there are as many butterflies as birds in North America. The larger part of the land animals are insects, and it is asserted that the larger proportion of the animal matter existing on the lands of the globe is probably locked up in the forms of insects. Insects vary in size from little beetles, of which it would take 100, placed end to end, to measure an inch, up to tropical species 6 or 8 inches in length, or of equal bulk to a mouse. Insects have a very long, but, as yet, very imperfect pedigree extending through the geological ages to Silurian times. Fossil remains of many different kinds of insects have been found in the rocks (Fig. 1295); even such delicate insects as plant-lice left their impress on the rocks ages ago. In the carboniferous or coal age, the insect world was evidently quite different from that of today, for fossils of veritable insect mammoths have been found; dragon-flies with a wing-expanse of 2 to 3 feet then existed. Insect fossils found in the tertiary rocks

1296. The four stages in an insect's life—egg, larva, pupa, imago.—The codlin-moth. (Egg much enlarged; others  $\times 1\frac{1}{2}$ )

sexes, as a means of communication, or possibly to express their emotions. Some think that bees and ants hear sounds too shrill for our ears. Insects have no true voice, but produce various noises mechanically, either by rapid movements of their wings, which causes the humming of bees and flies, or by friction between roughened surfaces on the body or its appendages, thus producing the rasping sounds or shrill cries of some crickets and grasshoppers. The house-fly hums on F, thus vibrating its wings 335 times in a second, while the wing tone of the honey-bee is A. Usually the males are the musicians of the insect world, but it is the female of the familiar mosquito which does the singing, and the "biting" also. The male mosquito doubtless hears the song of his mate by means of his antennæ, as the song causes the antennal hairs to vibrate rapidly. Organs which are structurally ear-

like have been found in various parts of the body of insects. The common brown grasshoppers of the fields have a large ear on each side of the first segment of the abdomen; one can easily distinguish with the naked eye the membrane or tympanum stretched over a cavity. Many of the long-horned green grasshoppers, katydids and crickets have two similar ears on the tibia

indicate that there were even more kinds of insects than now.

*Their growth and transformations.* Fig. 1296.—Insects begin life as an egg; in some cases the egg stage is passed within the body of the mother, which then gives birth to living young. The eggs of insects exhibit a wonderful variety of forms, sizes, colors and characteristic markings. A single scale insect may lay thousands of eggs, while some plant-lice produce only one. Remarkable instinct is often shown by the mother insect in placing her eggs where her young will find proper food. From their birth the young of some of the lowest or most generalized insects closely resemble their parents, and they undergo no striking change during their life; hence are said to have no metamorphosis. In the case of grasshoppers, stink-bugs, dragon-flies, and many

1300. A maggot. Larva of a dipterous insect.

1301. A grub. Larva of a beetle.

other insects, the young at birth resemble their parents, but have no wings. As they grow, wings gradually develop and often changes in markings occur, until the adult stage is reached. The growth, however, is gradual, and no striking or complete change occurs, and these insects are said to undergo an incomplete metamorphosis. The young insects in all stages are called *nymphs* (Fig. 1297); thus insects with an incomplete metamorphosis pass through three different forms during their life: an *egg*, the young or *nymph* stage, and the *adult*. From the eggs of butterflies, moths, flies, beetles, bees and some other insects, there hatches a worm-like creature, much unlike the parent insect. It is called a *larva* (Fig. 1298); the larvæ of butterflies and moths are often called *caterpillars* (Fig. 1299); *maggots* are the larvæ of flies (Fig. 1300); and the term *grub* is applied to the larvæ of beetles and bees (Fig. 1301).

When these larvæ get their full growth, some of them go into the ground where they form an earthen cell, while others proceed to spin around themselves a silken home or *cocoon* (Figs. 1302–1304). In these retreats the larvæ change to a quiescent or lifeless-appearing creature which has little resemblance to either the larva or the parent insect. It is called a *pupa* (Fig. 1305). The pupæ of butterflies are often called *chrysalids*. Flies change to pupæ in the hardened skin of the maggot. Some pupæ, like those of mosquitos, are very active. Wonderful changes take place within the skin of the pupa. Nearly all the larval tissues break down and the insect is practically made over, from a crawling larva to a beautiful, flying adult insect. When the adult is fully formed, it breaks its pupal shroud and emerges to spend a comparatively brief existence as a winged creature. Such insects are said to undergo a complete metamorphosis, and pass through four strikingly different

1303. Lengthwise section of the *Promethea* cocoon.

Showing at apex the valve-like opening through which the moth escaped.

*How they grow.*—Many persons think that the small house-flies grow to be the large ones. While most insects feed after they become adults, they get little or none of their growth during their adult life. Insects grow mostly while they are larvæ, or nymphs. The maggots from which the little house-flies develop doubtless do not have as luxuriant or favorable feeding-grounds as do those of the larger flies. In thirty days some leaf-feeding caterpillars will increase in size 10,000 times; and a certain flesh-feeding maggot will in twenty-four hours consume two hundred times its own weight, which would be paralleled in the human race if a one-day-old baby ate 1,500 pounds the first day of its existence! The skin of insects is so hard and inelastic that it cannot stretch to accommodate such rapid growth. But nature obviates this difficulty by teaching these creatures how to grow a new suit of clothes or a new skin underneath the old one, and then to shed or molt the latter. The old skin is shed in its entirety, even from all the appendages, and sometimes remains in such a natural position where the insect left it as to easily deceive one into thinking that he is looking at the insect rather than at its cast-off clothes. Some insects are so neat and economical that they devour their old suits or skins soon after molting them. Larvæ, or nymphs, may molt from two or three to ten or more times; the larvæ do not often change strikingly in appear-

ance, but the nymphs gradually acquire the characters and structures of the adult.

*How they eat.*—To the horticulturist, the mouth-parts of an insect are its most important organs or appendages. The mouth-parts are built on two very different plans.

1307. Imago of a tent-caterpillar.

Grasshoppers, beetles, caterpillars and grubs have two pairs of horny jaws, working from side to side, with which they bite or chew off pieces of their food, that then pass into the food-canal for digestion (Fig. 1312). The scale insects (Fig. 1313), plant-lice, true bugs (Fig. 1314), mosquitos and others have these jaws drawn out into thread-like organs, which are worked along a groove in a stiff beak or extended under-lip. Such insects can eat only liquid food, which they suck with their beak-like mouth-parts. The insect places its beak on the surface of the plant, forces the thread-like jaws into the tissues, and then begins a sucking operation, which draws the juices of the plant up along the jaws, and the groove in the beak into the food-canal of the insect. Thus a sucking insect could not partake of particles of poison sprayed on the surface of a plant. Its mouth-parts are not built for such feeding, and as it is impracticable to poison the juice of the plant, one is forced to fight such insects with a deadly gas, or each individual insect must be actually hit with some insecticide. A knowledge of these fundamental facts about the eating habits of insects would have saved much time and money that have been wasted in trying to check the ravages of sucking insects with paris green and similar poisons. Some insects, like the fruit flies, have mouth-parts fitted for lapping up liquids.

1308. A beetle. The adult of a borer larva.

#### Beneficial insects.

The horticulturist has many staunch and true friends among the insects. The honey-bee, the many wild bees, and other insects, as they visit the blossoms to get food for themselves, for their young, and honey for man, leave an insurance policy in the shape of tiny grains of pollen, which often insures a crop of fruit that otherwise might be extremely uncertain. The honey-bee is often accused of biting into ripe fruits, especially grapes. They have not yet been proved guilty, and careful, exhaustive experiments have shown that they will not do it under the most favorable circumstances. Wasps and other strong-jawed insects are responsible for most of this injury, the bees only sipping the juice from the wound. See *Bees*, Vol. I.

1309. One of the weevil beetles. With a long and strong proboscis.

Most of the pretty little beetles known to every child as "lady-bugs" eat nothing but injurious insects; many other beetles are also predaceous. Man is also often deeply indebted to many of the two-winged insects or true flies whose larvæ live as parasites inside the body of insect pests or feed upon them predaceously. Were it not for the ravenous larvæ of the "lady-bugs" and of the syrphus flies, plant-lice of all kinds would soon get beyond control. While man must recognize these little friends as valuable aids in his warfare against the hordes of insect pests, it will rarely be safe

to wait for the pests to be controlled by their enemies. Fig. 1315 shows a tomato worm bearing the cocoons of a parasite. Fig. 1310 shows one of the predaceous beetles destroying a cutworm.

#### Injurious insects.

There are now several thousand different kinds of insects that may be classed as injurious in the United States and Canada. Over 600 kinds were exhibited at the Columbian Exposition in 1893. All of these may not be injurious every year, as most insect pests have periods of subsidence, when certain factors, possibly their enemies or perhaps climate conditions, hold them in check. The outlook for American horticulturists, so far as injurious insects are concerned, is not encouraging. Nowhere else in the world are insects being fought as intelligently, successfully and scientifically as in America, yet we never have exterminated, and it is very doubtful if we ever will, a single insect pest. This means that American horticulturists will never have any fewer kinds of insects to fight. On the contrary, there are many more insect pests now than in our grandfather's early days, and new pests are appearing every year. This alarming state of affairs is largely due to two causes, for both of which man is responsible. Man is continually encroaching upon and thereby disturbing nature's primitive domain and the equilibrium which has there become established between animals and plants. In consequence, insects like the Colorado potato beetle, the apple-tree or the peach-tree borers have been attracted from their original wild food-plants to man's cultivated crops, which often offer practically unlimited feeding-grounds. Most of the new insect pests, however, are now coming to America from foreign shores. American horticulturists are continually importing plants from the ends of the earth, and oftentimes the plants are accompanied by one or more of their insect pests. Some comparatively recent introductions of this kind are the sinuate pear-borer, the pear midge, the gypsy moth, the brown-tail moth, the horn-fly and the elm leaf-beetle; such standard pests as the Hessian fly, the cabbage butterfly, the currant-worm, the codlin-moth (Fig. 1296) came in many years ago. Of the seventy-three insects which rank as first-class pests, each of them almost annually causing a loss of hundreds of thousands of dollars, over

1310. Ground beetle. One of the commonest predaceous insects.

1311. Moths of the peach-tree borer. The lowest one is male.

one-half have been introduced from foreign countries, mostly from Europe. It is a significant fact that usually these imported insects become much more serious pests here than in their native home; this is doubtless largely due to the absence of their native enemies, to more favorable climatic conditions here, and to a less intense system of agriculture in this country. Most of our worst insect pests of the fruits, of the garden crops, of the granary, of the household, of the greenhouse,

1312. Mouth-parts of a biting insect.

and practically all of our most dangerous scale insects, are of foreign origin. Man will continue to encroach on and disturb nature's primitive domain, and commercial operations will never cease, nor is there much hope of ever effectually quarantining our shores against these little foes; hence there seems to be no practicable way to stop this increase of the insect enemies of the horticulturist. The one who is the best fitted by nature, and who best fits himself with a knowledge of these pests and how to fight them, will usually be the one

to survive and reap the reward of profitable crops. No part of a plant, from its roots to the fruit it produces, escapes the tiny jaws or the sucking beaks of insects.

#### *Root-feeding insects.*

—Many of the small fruits and vegetables are often seriously injured by insects feeding on the roots. The grape-vine fidia (the grub of a small beetle) and the grape phylloxera plant-louse live on grape roots. Strawberries often succumb to the attacks of the grubs of several small beetles known as strawberry-root worms, and to the large white grubs of the May beetles. The roots of cabbages, radishes and

1313. San José Scale.

Showing the mature winter scale; also the insect itself, with its thread-like feeding organs.

other cruciferous plants are often devoured by hordes of hungry maggots. These underground root-feeding insects are difficult pests to control, like any other unseen foe. Sometimes they can be reached successfully by injecting a little carbon bisulfide into the soil around the base of the plant. The cabbage maggots can be prevented largely by the use of tarred paper pads placed around the plants, or by pouring a carbolic acid emulsion at the base of the infested plants. The strawberry root-feeders are best controlled by frequent cultivation and a short rotation of crops.

**Borers.**—These are the larvæ of several different kinds of insects, which burrow into and feed upon the inner bark, the solid wood, or the interior pith of the larger roots, trunks, branches, and stems or stalks of many horticultural plants. Nearly every kind of fruit trees is attacked by its special kind of borer, as are

1314. Hemipterous insect. Known to entomologists as a true bug.

also many of the smaller vine and bush-fruits and garden crops. Borers are often the most destructive of insect pests. The two apple-tree borers, the round-headed (Fig. 1316) and the flat-headed species, and the peach-tree borer (Fig. 1311) doubtless cause the death of as many apple and peach trees in America as all other enemies combined. The fruit-bark beetles, or "shot-hole" borers, usually attack only unthrifty or sickly fruit trees, and a tree once infested by them is usually doomed. Two borers, one the grub of a beetle

1315. Tomato worm attacked by parasitic insects.

and the other the caterpillar of a moth, sometimes tunnel down the stems of currants and gooseberries. Raspberries and blackberries (Fig. 1317) also suffer from two or three kinds of borers, one working in the root, one in the stem, and a maggot bores down and kills the new shoots. A caterpillar closely allied to the peach-tree borer lives in squash vines, often ruining the crop. The potato-stalk weevil sometimes does much damage in potato fields. Sometimes one can prevent borers from getting into a fruit tree with a paper bandage closely wrapped around the part liable to be attacked, or by the application of some "wash." Most of the washes recommended will prove ineffectual or dangerous to use. Gas-tar has given good results, but some report injury to peach trees from its use; hence one should first experiment with it on a few trees. No way has been found to keep borers out of the small fruits or garden crops; usually if infested canes, stems or plants are cut out and burned early in the fall or whenever noticed, most of the borers will be killed. When borers once get into fruit trees, the "digging-out" process is usually the only resort, although some report that they readily kill the depredator by simply injecting a little carbon bisulfide into the entrance of his burrow and quickly closing it with putty.

#### *Bud- and leaf-feeding insects.*

—The buds and leaves of horticultural crops often swarm with legions of biting and sucking insects. A mere enumeration of the different kinds of these pests would weary the reader. Some insects, like the rose chafer, work on several different kinds of plants, while many others attack only one or two kinds. In apple orchards, the opening buds are seized upon by the hungry bud-moth and case-bearing caterpillars, by

1316. Burrows of an apple-tree borer.

The holes at a show where the imago or beetle emerged.

the newly hatched canker-worms, and by tent-caterpillars, whose tents or "sign-boards" are familiar objects in many orchards. These pests continue their destructive work on the leaves. The pear slug often needs to be checked in its work of skeletonizing the leaves of

the pear and cherry. The pear psylla, one of the jumping plantlice, is a very serious menace to pear-growing in many localities; the fruit is either dwarfed or drops from badly infested trees, and sometimes so many little pumps sucking out its life finally cause the death of the tree. The little blue grapevine flea-beetle often literally nips the prospective crop of fruit in the bud, or the rose-chafer may swarm over the vines and eat the foliage or blossoms. Currant and gooseberry growers realize that eternal vigilance against the familiar green currant worms is the price of a crop of fruit. The asparagus beetles would soon appropriate every asparagus shoot that appears in many localities. It is a

continual struggle against insect pests to get a paying crop of almost any vegetable. The several kinds of cabbage caterpillars would soon riddle the leaves. The hungry striped cucumber beetles can hardly wait for the melon, squash, or cucumber vines to come up. Two sucking insects, the harlequin cabbage bug and the squash stink-bug, are equally as destructive as their biting relatives. The bud- and leaf-feeding insects are usually readily controlled by spraying some poison on their food, or by hitting them with some oil or soap spray. As the female moths of canker-worms are wingless, a wire trap or sticky bandage placed around the trunk of the tree in the late fall and early spring, to capture the moths as they crawl up the tree to lay their eggs, will greatly help to check these serious pests. The collection and burning of the conspicuous egg-rings of the

tent-caterpillars at any time between August and the following April will greatly reduce the vast numbers of shiftlessness in apple orchards. Hand-picking or collecting is the most successful method of controlling the rose-chafer, harlequin cabbage bug, and

*Fruit-eating insects.*—"Wormy" apples, pears, quinces, plums, peaches, cherries, apricots, grapes, currants and nuts are often the rule rather than the exception. The codlin-moth or apple-worm often ruins from one-third to one-half of the crop each year in many localities; it also infests pears seriously. The apple maggot tunnels its way through and through the flesh of a large percentage of the apples in the northern sections of the country. Most of the wormy plums, peaches, cherries and apricots are the work of the grub of that worst insect enemy of the stone fruits—the plum curculio; the plum gouger, a similar insect, whose grub works in the pit of plums, is equally destructive to this fruit in some states. "Knotty" quinces are largely the work of the adults of the quince curculio, while its grub often ruins the fruit with its disgusting worm-hole. There is also a grape curculio that, with the aid of the caterpillar of a little moth, works havoc in grapes. Currants and gooseberries are often wormy from the work of two or three different kinds of maggots and caterpillars. Two kinds of

fruit flies attack the cherry; infested cherries may show no external signs of the presence of the maggot reveling in the juices within. Various small beetles known as weevils, are responsible for most wormy nuts. Most of the fruit-eating insects are out of the reach of the ordinary insecticides. The codlin-moth is a noted exception, however, for the peculiar habit that the little caterpillar has of usually entering the blossom end of the fruit and feeding therein for a few days, gives the man with a poison spray a very vulnerable point of attack. It is only necessary to spray a bit of poison into the open calyx cup within a few days after the petals fall, and let nature soon close the calices and keep the poison therein until the newly-hatched caterpillar includes it in its first menu. Often 95 per cent of the apples that would otherwise be ruined by the worms are saved by an application of paris green at this critical time.

*Plant-lice.*—Scarcely a plant escapes the little suction pump or beak of some kind of a plant-louse or aphid. More than 300 different kinds of plant-lice have been identified in the United States, and nearly every kind of fruit, flower, farm or garden crop has its special plant-louse enemy, which is often a serious factor in the production of a crop. These little creatures are so small, so variable, so hard to perceive, present so many different forms in the same species, and have such varied and interesting life-stories to tell, that what is known about them is but a mere beginning as compared to what is yet to be learned. It would take a large volume to include the interesting stories which might be told of the lives and of the relations with ants of some of the commonest of these plant-lice. No other group of insects presents so many curious, varied, interesting, and wonderful problems of life as do the aphids. In the aggregate, the damage done by plant-lice is very great.

1317. A beetle borer and its work.

The larva bores in the young wood of raspberry and blackberry canes, causing the swellings seen in the picture.

1318. Grasshopper. (Mounted)

the squash stink-bug in many cases. Prompt action, guided by a knowledge of the insect's habits and life-history, and any intelligent use of materials and apparatus, are essential in any successful effort to control these bud- and leaf-feeding pests of the horticulturist.

1319. A crane fly. (Mounted)

1320. A snapping beetle. (Mounted)

At times hundreds of acres of peas have been ruined by an aphid. Nursery stock often suffers severely and bearing fruit trees are often seriously injured by them. About forty different kinds of aphides live in greenhouses where a perpetual warfare has to be waged against them. In four

years nearly 100 generations of a common aphid have been reared in greenhouses, and there were no indications of any egg-stage or of male forms during this time, so that they may thus breed indefinitely in houses, their young being born alive and no males appearing. The standard remedies for plant-lice are whale-oil soap, kerosene emulsion, and tobacco in various ways (as a decoction, dry as a dust, or in the form of similar extracts), and these are successfully used to kill the aphides in all situations.

**Scale insects.**—Since the advent of San José scale into the eastern United States, scale insects of all kinds have attracted world-wide attention. They are all small insects, and derive their name from the fact that their tender bodies are protected by hard, scale-like coverings secreted by the insects. Thus protected, they are difficult insects to kill, and as they are easily transported on nursery stock, buds or cions, and also multiply rapidly,

1321. A spreading board for drying soft-winged insects.

the scale insects are justly to be considered as among the most dangerous and destructive of injurious insects. A single female San José scale may rear a brood of from 100 to 600 young, and there may be four or five generations a year; and more than 2,000 eggs have been laid by a single *Lecanium* scale. The scale insects, the dreaded San José species included, can be controlled successfully by judicious, intelligent and timely work with sprays of lime-sulfur, crude petroleum, or hydrocyanic acid gas, which should be used in the case of nursery stock. Since 1889 fumigation with hydrocyanic acid gas has been extensively practised in the citrus orchards of California, and now Florida and South African fruit-growers are also using it in their orchards. Large gas-tight tents or boxes are placed over the trees and the gas then generated within. Much nursery stock is now treated with the gas in tight boxes or houses; this is required by law in many states, and it should be practised in other regions. Recently greenhouses, railway coaches, rooms in private houses, and whole flouring mills have been effectively fumigated with this gas.

Insects are preserved in collections by securing them in tight cases by means of a pin inserted through the thorax, or through the right wing if the subject is a beetle. Moths and butterflies are pinned in position on a spreading-board until thoroughly dried. See Figs. 1318-1322. Every horticulturist should make a collection of injurious insects.

**Insect literature for horticulturists.**—Horticulturists should keep in close touch with the experiment stations and state entomologists of their own and of other states, and also with the Department of Agriculture at Washington; for it is from these sources that the best and latest advice regarding injurious insects is now being disseminated free, either by personal correspondence or by means of bulletins. Among the books, one or more of which may well find a place in a horticulturist's library are the following: Weed's "Insects and Insecticides," Lodeman's "The Spraying of Plants," Saunders' "Insects Injurious to Fruits," Sanderson's "Insect Pests of Orchard, Farm and Garden," and Slingerland and Crosby's "Fruit Insects."

C. R. CROSBY†

#### Other invertebrate animals.

**Mites.**—Mites belong to the class of animals known as Arachnida, which are closely related to insects. Spiders and scorpions also belong in this group. Mites are small creatures, usually possessing four pairs of legs when mature, and the body is not divided into three divisions as in the case of insects. The greenhouse red-spider (*Tetranychus bimaculatus*) is one of the most common and injurious species. It occurs on a wide variety of plants grown under glass and also out-of-doors on the foliage of many wild and cultivated plants. It is about  $\frac{1}{16}$  in. long and varies in color from yellow through orange to brown and dark green, often with a darker spot on each side of the body. It spins a very delicate silken web-like nest over its breeding-ground. It can be killed on the foliage of plants grown in the open with soap solution, dusting with sulfur, and hydrated lime, or by using a flour-paste spray. In greenhouses, it is best controlled by repeated spraying with water, using much force and little water to avoid drenching the beds.

The clover mite (*Bryobia pratensis*) is a minute, spider-like, oval, reddish brown mite about  $\frac{1}{100}$  inch in length with long front legs. It attacks the foliage of many fruit and forest trees as well as clover and grasses. The tiny, round, reddish eggs often occur in great numbers on the bark of trees in winter giving the branches a reddish color. It may be controlled by the same treatment as for red-spider. In addition, the eggs may be killed with a lime-sulfur solution while the trees are dormant.

The pear-leaf blister-mite (*Eriophyes pyri*) differs from most other mites in having only two pairs of legs and in its elongate body. The mite is only  $\frac{1}{100}$  inch in length; it burrows in the tissue of the leaf, causing blister-like galls. The eggs are laid within the gall,

1322. A cross-section of spreading board in front of the cleat "d," in Fig. 1321.

and some of the mites when mature leave through a small opening and migrate to new leaves. The mature mites hibernate under the bud-scales. This pest is controlled by applications of lime-sulfur or miscible oils while the trees are dormant.

**Nematodes.**—A species of nematode worm (*Heterodera radiculicola*) lives parasitically in the roots of a wide variety of wild and cultivated plants producing enlarged knots or swellings. This disease is known as

root-knot and is more prevalent in light soils. It is especially troublesome in greenhouses. The adult female worm is flask-shaped, .5 to 1 mm. in length, pearly white in color, and is found within the knots on the roots. Each female lays several hundred eggs. The young worms may continue within the same root or migrate through the soil to others. Nematode root-galls have been found on nearly 500 different species of plants. It is especially destructive to okra, hollyhock, *Amarantus tricolor*, peach, snapdragon, celery, heart-leaved basil, wax gourd, beet, rape, red pepper, balloon vine, melon papaw, catalpa, endive, watermelon, coffee, muskmelon, cucumber, squash, pumpkin, carrot, deutzia, California poppy, fig, soybean, pecan, morning-glory, lettuce, gourd, sweet pea, flax, tomato, tobacco, peony, ginseng, passiflora, petunia, tuberose, cherry, pomegranate, eggplant, potato, salsify, clovers, violet, Old World grape. See page 1023.

This pest may be controlled in greenhouses by the use of live steam to sterilize the soil or by a weak solution of formaldehyde, one part, 36 to 40 per cent formaldehyde, to one hundred parts water, applied at the rate of one to one and one-half gallons to every square yard of soil surface of shallow beds. After the application, the soil should be thoroughly stirred and planting should not be done till at least ten days later. Under field conditions, the problem is more difficult. The most feasible method is a system of crop-rotation in which an immune crop is grown for at least two years between susceptible crops. One of the most resistant crops is the Iron variety of cowpea. Clean cultivation should be practised so as to destroy all susceptible plants.

### Insecticides.

Insecticides are substances used to kill insects, as poisons, washes and gases. Insects are subject to many natural checks, such as wind, rains, sudden changes of temperature, the attacks of parasites and predaceous enemies, and are often destroyed in great numbers by bacterial and fungous diseases. In spite of these natural checks it is, however, usually necessary to resort to a spray or some other artificial insecticide for the protection of our crops.

The essential requirements for a satisfactory insecticide are: efficient killing power, safety to the foliage, cheapness and ease of application. The choice of an insecticide for any particular case will depend upon a number of factors: upon the structure, habits, and life-history of the insect to be killed; and upon the susceptibility of the host plant to injury, its mode of growth and the conditions under which it is cultivated. Some insects, as the plant-lice, are soft-bodied and provided with a thin and delicate integument; others, like the beetles and wireworms, have hard, horny shells impervious to ordinary spray liquids; some insects bite off and swallow portions of the plant, while others merely suck out the sap by means of a slender tube; some are injurious in the larval stage, others as adults; some attack the roots, some the foliage and fruit, while others burrow in the trunk and branches. Plants vary greatly in their susceptibility to injury from the use of insecticides; the peach and Japan plum have especially tender foliage, while the apple is not so easily injured. All these points and many more must be considered in selecting an insecticide which will be adapted to the control of any injurious insect. Our methods of fighting insects are constantly changing as new facts are discovered, new methods devised and new insecticides invented. Our present methods are the results of a more or less unconscious coöperation extending over many years between the practical grower, the student of insect life and the progressive manufacturers of spraying materials and spray machinery.

Insecticides may be classed into those which are eaten with the food and kill by poisoning; those that

kill by contact with the insect's body; and fumes of gases used for fumigation. The poisons are effective against the biting or chewing and lapping (fruit flies) insects; the contact insecticides are used as a rule against sucking insects; and fumes and gases are employed principally in greenhouses and for the fumigation of nursery stock, stored seeds, and citrus trees.

### Poisoning insecticides.

The most widely used substance for the poisoning of insects is arsenic in its various compounds. For this purpose only compounds insoluble in water can be used, as soluble arsenic is very injurious to foliage.

*White arsenic.*—This is the cheapest form in which arsenic can be obtained. It is a white powder, soluble in water and very injurious to foliage. A cheap and efficient insecticide may be prepared from it as follows:

*For use with bordeaux mixture only.* Sal-soda, two pounds; water, one gallon; arsenic, one pound. Mix the white arsenic into a paste and then add the sal-soda and water, and boil until dissolved. Add water to replace any that has boiled away, so that one gallon of stock solution is the result. Use one quart of this stock solution to fifty gallons of bordeaux mixture for fruit trees. Make sure that there is enough lime in the mixture to prevent the caustic action of the arsenic.

*For use without bordeaux mixture.* Sal-soda, one pound; water, one gallon; white arsenic, one pound; quicklime, two pounds. Dissolve the white arsenic with the water and sal-soda as above, and use this solution while hot to slake the two pounds of lime. Add enough water to make two gallons. Use two quarts of this stock solution in fifty gallons of water.

As there is always some danger of foliage injury from the use of these home-made arsenic compounds, and as they cannot be safely combined with the dilute lime-sulfur when used as a summer spray, they are now rarely employed in commercial orchard spraying.

*Paris green.*—Paris green is composed of copper oxid, acetic acid and arsenious oxid chemically combined as copper-aceto-arsenite. By the National Insecticide Law of 1910, paris green must contain at least 50 per cent arsenious oxid and must not contain arsenic in water-soluble form equivalent to more than 3½ per cent arsenious oxid. For many years paris green has been the standard insecticide for orchard use, but is now largely replaced by the safer and more adhesive arsenate of lead. In spraying apples, paris green is used at the rate of one-half pound to one hundred gallons of water or bordeaux mixture. When used with water, lime twice the bulk of the paris green should be added to lessen the danger of foliage injury. Paris green cannot safely be used with either the dilute lime-sulfur as used for summer spraying or with the self-boiled lime-sulfur.

*London purple.*—London purple is an arsenite of lime and is a by-product in the manufacture of aniline dyes. Its composition is variable, the arsenic content varying from 30 to 50 per cent. Owing to the presence of much soluble arsenic it is likely to cause foliage injury, and it is now little used in commercial spraying.

*Arsenate of lead.*—Arsenate of lead was first used as an insecticide in 1893, in Massachusetts. It has now almost entirely replaced paris green for orchard work throughout the country. It adheres better to the leaves, may be used at considerably greater strength without injuring the foliage and may be combined with a dilute lime-sulfur solution or with the self-boiled lime-sulfur. Chemically, arsenate of lead may be either triplumbic arsenate or plumbic-hydrogen arsenate. The commercial product usually consists of a mixture of these two forms, the proportion depending on the method of manufacture employed. It is usually sold in the form of a thick paste, but for some purposes the powdered form is preferred. Under the National Insecticide Law of 1910, arsenate of lead paste must not contain more than 50 per cent water and must contain the arsenic equivalent of at least 12½ per cent arsenious oxid. The water-soluble arsenic must not exceed an equivalent of three-fourths of 1 per cent of arsenic oxid. In the best grades of arsenate of lead paste the chemical is in a finely divided condition, and thus when diluted for use remains in suspension for a considerable time. Arsenate of lead is used at various strengths, depending upon the insect to be killed and on the susceptibility of the foliage to injury. Four pounds in one hundred gallons can be used on the peach if combined with the self-boiled lime-sulfur; on apple, four or five pounds in one hundred gallons is usually sufficient; on grapes for killing the grape root-worm beetles and the rose-chaffer, eight to ten pounds in one hundred gallons have been found necessary. The poison is more readily eaten by these beetles if sweetened by two gallons of molasses in one hundred gallons, but, unfortunately, the addition of molasses greatly decreases the adhesiveness of the poison. Some species of fruit flies may be controlled by the use of sweetened arsenate of lead sprayed on the foliage of the plants at the first appearance of the flies. They lap up the poison with their fleshy tongue-like mouth-parts and succumb before ovipositing.

*Arsenite of zinc.*—Arsenite of zinc is a light fluffy powder and contains the equivalent of about 40 per cent arsenious oxid. It has been used extensively on the Pacific slope as a substitute for arsenate of lead. It kills somewhat more quickly and is fairly safe on apple foliage when used with bordeaux mixture or with lime. When sweetened with molasses, it is injurious to foliage. One pound of zinc arsenite is equivalent to about three pounds of arsenate of lead. In orchard experiments, as a rule, it has not shown that it is superior to the latter.

**Hellebore.**—Hellebore is a light brown powder made from the roots of the white hellebore plant (*Veratrum album*), one of the lily family. It is applied both dry and in water. In the dry state, it is usually applied without dilution, although the addition of a little flour will render it more adhesive. In water, four ounces of the poison is mixed with two or three gallons, and an ounce of glue, or thin flour paste, is sometimes added to make it adhere. A decoction is made by using boiling water in the same proportions. Hellebore soon loses its strength, and a fresh article should always be demanded. It is much less poisonous than the arsenicals, and should be used in place of them upon ripening fruit. It is used for various leaf-eating insects, particularly for the currant-worm and rose-slug.

### Contact insecticides.

The most important contact insecticides are soaps, sulfur, sulfur compound, and oily or resinous emulsions.

**Soaps.**—The most commonly used soap solution is that prepared from fish-oil soap. The commercial brands of this soap are usually by-products and contain many impurities; further, many of them contain an excess of free or uncombined alkali and are thus likely to injure young and tender foliage. A good fish-oil soap may be prepared by the following formula: Caustic soda, six pounds; water, one-half gallon; fish-oil, twenty-two pounds. Dissolve the caustic soda in the water and then add the fish-oil gradually under constant and vigorous stirring. The combination occurs readily at ordinary summer temperatures, and boiling is unnecessary. Stir briskly for about twenty minutes after the last of the oil has been added. There is now on the market a good brand of insecticide soap prepared from cotton-seed oil soap stock or from an impure grade known as pancoline.

**Sulfur.**—Sulfur may be obtained in two forms,—flowers of sulfur and flour of sulfur. In the form of a powder or dust, sulfur is especially valuable against red-spider. In California, flowers of sulfur mixed with equal parts of hydrated lime is blown on the trees for the control of red-spider and mite. It may also be used for the same purpose mixed with water at the rate of one pound in three gallons of water, to which has been added a little soap to keep the sulfur in suspension. The mixture should be agitated constantly during spraying. The sulfur remains longer in suspension if it is first made into a paste with water containing one-half of 1 per cent of glue. Page 1028.

**Lime-sulfur solution.**—A solution of lime-sulfur was first used as an insecticide in California in 1886. It is now the standard remedy for blister mite, San José scale and similar scales, as well as an efficient fungicide. The lime-sulfur solution may be purchased in the concentrated form or may be prepared as follows: Lump lime (95 per cent calcium oxide), thirty-eight pounds; lump lime (90 per cent calcium oxide), forty pounds; sulfur, eighty pounds; water, fifty gallons. Make a paste of the sulfur with about ten gallons of hot water. Add the lime. As the lime slakes, add hot water as necessary to prevent caking. When the lime has slaked, add hot water to make fifty gallons and boil one hour, stirring constantly. Water should be added from time to time to keep the liquid up to fifty gallons. Store in air-tight hardwood barrels. Test the strength of the solution with a Baumé hydrometer and dilute for use according to the following table (see also p. 1029):

DILUTIONS FOR DORMANT AND SUMMER SPRAYING WITH LIME-SULFUR MIXTURES

Reading on hydrometer	Amount of dilution. Number of gallons of water to one gallon of lime-sulfur solution.		
	For San José scale	For blister mite	For summer spraying of apples

**Emulsions.**—Emulsions are oily or resinous sprays in which these substances are suspended in water in the form of minute globules, a condition brought about by the addition of soap. They form an important class of contact insecticides, useful particularly against scale insects and plant-lice.

**Kerosene emulsion.**—Kerosene emulsion is the oldest of our contact insecticides. It is especially valuable for use against plant-lice and other small, soft-bodied insects. It is prepared by the following formula: Soap, one-half pound; water, one gallon; kerosene, two gallons. Dissolve the soap in hot water; remove from the fire and, while still hot, add the kerosene. Pump the liquid back into itself for five or ten minutes or until it becomes a creamy mass. If properly made, the oil will not separate on cooling. For use on dormant trees, dilute with five to seven parts of water. For killing plant-lice on foliage, dilute with ten to fifteen parts of water.—Crude-oil emulsion is made in the same way by substituting crude oil in place of kerosene. The strength of oil emulsions is frequently indicated by the percentage of oil in the diluted liquid: for a 10 per cent emulsion, add seventeen gallons of water to three gallons of stock emulsion; for a 15 per cent emulsion, add ten and one-half gallons of water to three gallons of stock emulsion; for a 20 per cent emulsion, add seven gallons of water to three gallons of stock emulsion; for a 25 per cent emulsion, add five gallons of water to three gallons of stock emulsion.

**Distillate emulsion.**—Distillate emulsion is widely used in California. Distillate (28° Baumé), twenty gallons; whale-oil soap, thirty pounds; water, twelve gallons. Dissolve the whale-oil soap in the water which should be heated to the boiling point, add the distillate and agitate thoroughly while the solution is hot. For use, add twenty gallons of water to each gallon of the stock solution.

**Carbolic acid emulsion.**—This spray is used in California for mealy-bugs, plant-lice, and the soft brown scale: Whale-oil soap, forty pounds; crude carbolic acid, five gallons; water, forty gallons. Dissolve the soap completely in hot water, add the carbolic acid, and heat to the boiling point for twenty minutes. For use, add twenty gallons of water to each gallon of stock solution.

**Miscible oils.**—There are now on the market a number of concentrated oil emulsions, known as soluble or miscible oils, intended primarily for use against the San José scale. For this purpose they are fairly effective when diluted with not more than fifteen parts of water. To lessen danger of injury to the trees, applications should not be made when the temperature is below freezing, nor when the trees are wet with snow or rain. Methods have been devised for preparing these concentrated emulsions at home, but as there is considerable danger attending the process, it is better to buy them ready-made.

**Tobacco.**—Tobacco is one of our most useful insecticides. The poisonous principle in tobacco is an alkaloid nicotine, which in the pure state is a colorless fluid, slightly heavier than water, of little smell when cold and with an exceedingly acrid burning taste even when largely diluted. It is soluble in water and entirely volatile. It is one of the most virulent poisons known; a single drop is sufficient to kill a dog. Commercial tobacco preparations have been on the market for many years. The most important of these are black leaf, "black leaf 40," and nicofume.

**Black Leaf.**—Black leaf was formerly the most widely used tobacco extract. It contains only 2.7 per cent nicotine and has now been replaced by the more concentrated extracts. It is used for plant-lice at the rate of one gallon to sixty-five gallons of water.

**"Black leaf 40."**—"Black leaf 40" is a concentrated tobacco extract containing 40 per cent nicotine sulfate. Its specific gravity is about 1.25. In this preparation the nicotine is in a non-volatile form, it having been treated with sulfuric acid to form the sulfate. "Black leaf 40" is used at strengths varying from one part in 800 parts of water to one part in 1,600 parts. It can be satisfactorily combined with other sprays, as for example, lime-sulfur solution, arsenate of lead, and the various soap solutions. When used with water, about four pounds of soap should be added to make the mixture spread and stick better.

**Nicofume** is a tobacco extract containing 40 per cent of nicotine in the volatile form. It is intended primarily for use in greenhouses. Strips of paper soaked in this preparation are smudged in greenhouses to destroy aphids.

Tobacco is also used in the form of dust for the same purpose. It is especially valuable against roof-lice on asters and other plants. Tobacco extracts can be made at home by steeping tobacco stems in water, but as they vary greatly in nicotine content and are sometimes likely to injure tender foliage, it is better to buy the standardized extracts.

**Pyrethrum.**—A very fine, light brown powder, made from the flower-heads of species of pyrethrum. It is scarcely injurious to man. Three brands are on the market:

**Persian insect-powder,** made from the heads of *Pyrethrum roseum*, a species also cultivated as an ornamental plant. The plant is native to the Caucasus region.

**Dalmation insect-powder,** made from *Pyrethrum cinerariæ-folium*.

**Buhach,** made in California from cultivated plants of *Pyrethrum cinerariæ-folium*.

When fresh and pure, all these brands appear to be equally valuable, but the home-grown product is usually considered most reliable. Pyrethrum soon loses its value when exposed to the air. It is used in various ways:

(1) In solution in water, one ounce to three gallons. Should be mixed up twenty-four hours before using.

(2) Dry, without dilution. In this form it is excellent for thrips and lice on roses and other bushes. Apply when the bush is wet. Useful for aphids on house plants.

(3) Dry, diluted with flour or any light and fine powder. The poison may be used in the proportion of one part to from six to thirty of the diluent.

(4) In fumigation. It may be scattered directly upon coals, or made into small balls by wetting and molding with the hands and

then set upon coals. This is a desirable way of dealing with mosquitos and flies.

(5) In alcohol. (a) Put a part of pyrethrum (buhach) and four parts alcohol, by weight, in any tight vessel. Shake occasionally, and after eight days filter. Apply with an atomizer. Excellent for greenhouse pests. For some plants it needs to be diluted a little. (b) Dissolve about four ounces of powder in one gill of alcohol, and add twelve gallons of water.

(6) Decoction. Whole flower-heads are treated to boiling water, and the liquid is covered to prevent evaporation. Boiling the liquid destroys its value.

Good insect-powder can be made from *Pyrethrum roseum*, and probably also from *P. cinerariaefolium*, grown in the home garden.

1323. Device for discharging the cyanide into the acid.

**Bait, vegetable bait.**—Spray a patch of clover or some other plant that the insects will eat with paris green or some other arsenical; mow it close to the ground, and while fresh place it in small piles round the infested plants. To avoid wilting of the bait, cover the heaps with a shingle or piece of board.

**Bran-arsenic mash.**—White arsenic, one-half pound, or paris green, one pound; bran, fifty pounds. Mix thoroughly and then add enough water to make a wet mash. Sugar or molasses may be added, but is unnecessary. Poisoned baits are used against cutworms and grasshoppers.

**Kansas grasshopper bait.**—This bait is the most efficient means of controlling grasshoppers yet devised. It is prepared as follows: Bran, twenty pounds; paris green, one pound; syrup, two quarts; oranges or lemons, three fruits; water, three and one-half gallons. Mix the bran and paris green thoroughly in a wash-tub while dry. Squeeze the juice of the oranges or lemons into the water; chop the pulp and peel fine and add them also. Dissolve the syrup in the water and wet the bran and poison with the mixture, stirring at the same time so as to dampen the mash thoroughly. Sow the bait broadcast in the infested area early in the morning.

**Criddle mixture.**—Mix one pound of paris green with one-half barrel of horse droppings, and add one pound of salt if the material is not fresh. For use against grasshoppers.

**Gas tar** is used extensively for painting wounds to keep out the moisture and prevent the entrance of insects. It is also sometimes used on peach trees to keep out the borers. In this case it should be applied in the spring only, as there is danger of injuring the trees in the fall.

**Asphalt.**—Certain grades of asphalt have been used successfully on peach in California to keep out the Pacific peach tree-borer. Experiments in the eastern states indicate that it may be used to advantage against the common peach tree-borer.

**Hot-water.**—Submerge affected plants or branches in water at a temperature of about 125°. For aphids. It will also kill rose-bugs at a temperature of 125° to 135°.

**Gasolene torch.**—The gasolene torch has been successfully used for the control of scale insects on date palms in Arizona. The trees are first pruned closely, drenched with gasolene and fired. They are then scorched with a gasolene blast torch.

**Flour paste.**—Mix a cheap grade of wheat flour with cold water, making a thin batter, without lumps; or wash the flour through a wire screen with a stream of cold water. Dilute until there is one pound of flour in each gallon of mixture. Cook until a paste is formed, stirring constantly to prevent caking or burning. Add sufficient water to make up for evaporation. For use, add eight gallons of this stock solution to one hundred gallons of water. Used for red spider in California.

#### General practices.

**Cleanliness.**—Much can be done to check the ravages of insects by destroying their breeding-places and hiding-places. Weeds, rubbish, and refuse should be eliminated.

**Hand-picking** is often still the best means of destroying insects despite all the perfection of machinery and of materials. This is, particularly true about the home grounds and in the garden. The cultivator should not scorn this method.

**Promoting growth.**—Any course that tends to promote vigor will be helpful in enabling plants to withstand the attacks of plant-lice and other insects.

**Burning.**—Larvæ which live or feed in webs, like the tent-caterpillar and fall web-worm may be burned with a torch. The lamp or torch used in campaign parades finds its most efficient use here.

**Banding.**—To prevent the ascent of canker-worm moths and gypsy-moth caterpillars, various forms of sticky bands are in use. For this purpose there is no better substance than "tree tanglefoot." It may be applied directly to the tree-trunk, but when so used leaves an unsightly mark and requires more material than when the following method is used: First place a strip of cotton batting 3 inches wide around the trunk; cover this with a strip of tarred paper 5 inches wide; draw the paper tight and fasten at the lap only with three or four tacks. Spread the tanglefoot on the upper two-thirds of the paper, and comb it from time to time to keep the surface sticky. Burlap bands are made by tying or tacking a strip of burlap around the trunk and letting the edges hang down. The larvæ will hide under the loose edge, where they may be killed. Banding is now little used for codlin-moth, since spraying with poison has been found so much more effective.

#### Fumigation.

Poisonous gases are widely used in killing insects under certain conditions. Hydrocyanic acid gas is employed in the fumigation of greenhouses and citrus trees. It is a most deadly and effective material. In Europe, fumigation with this gas is known as cyaniding and cyanization. Nicotine preparations are used extensively in greenhouse fumigation. Carbon bisulfid is employed almost exclusively for the treatment of stored grains and seeds.

**Hydrocyanic acid gas.**—This gas is generated by adding potassium or sodium cyanide to dilute sulfuric acid. The gas is a deadly poison, and great care should be taken not to inhale it. One breath is fatal!

Potassium cyanide is a white amorphous salt that readily absorbs moisture when exposed to the air. Pure potassium cyanide contains 40 per cent of cyanogen (CN) by weight. When potassium cyanide (KCN) is placed in dilute sulfuric acid the cyanogen (CN) unites with the hydrogen (H) of the acid ( $H_2SO_4$ ) to form hydrocyanic acid gas (HCN). In the preparation of this gas for fumigation purposes use a potassium cyanide which is at least 98 per cent pure. The chemicals should always be combined in the following proportions: Potassium cyanide, one ounce; sulfuric acid, one fluid ounce; water, three fluid ounces.

Always use an earthen dish, *pour in the water first*, and add the sulfuric acid. When all is ready, drop in the proper quantity of potassium cyanide and retire

1324. Shed for the fumigation of nursery stock.

immediately, before the gas arises. Fig. 1323 shows a device used abroad (from the "Gardening World") for dumping the cyanide (at 4) into the acid by means of a cord that extends outside the house.

*White-fly.*—The quantity of chemicals used for a given space will depend on the nature of the insects to be killed and the susceptibility of the plants to injury. This quantity is usually indicated by amount of potassium cyanide required for each 100 cubic feet of space. For treating white-fly on tomatoes in green-houses, use one ounce to 3,000 cubic feet, letting the fumigation continue all night. The same treatment applies for cucumber. Fumigate on dry, dark nights when there is no wind. The house should be as dry as practicable and the temperature not above 60° F.

**Greenhouses.**—No one formula can be given for fumigating with hydrocyanic acid gas the different kinds of plants grown in greenhouses, as the species and varieties differ greatly in their ability to withstand the effects of the gas. For the general run of greenhouse subjects, the practice is to use one ounce of potassium cyanide, one ounce of sulfuric acid, two ounces water, to each 2,000 cubic feet of space. The cyanide should be 98 per cent pure. Fumigate at night when there is no wind and when the plants are dry and the house cool; leave the house closed till morning, and open it up and let it air out before entering it. This applies to chrysanthemums, cinerarias, azaleas, bulbs, carnations and other common plants.

Ferns and roses are very susceptible to injury, and fumigation, if attempted at all, should be performed with great care. In cases of doubt, or when there is reason to suspect that the plants are particularly susceptible, and when one does not have definite instructions, it is well to fumigate with the weakest strength in use, and increase it in subsequent fumigations if the insects are not killed and if the plants are not injured.

Violets are very susceptible to injury from tobacco fumigation, and commercial growers therefore regularly use hydrocyanic acid gas for the control of "green-fly" and "black-fly," two species of plant-lice. The latter is much more difficult to kill. For over-night fumigation from one-fourth to one-half ounce potassium cyanide to each 1,000 cubic feet is generally used. Sometimes one ounce potassium cyanide to each 1,000 cubic feet is used, the fumigation continuing only from twenty-five to thirty-five minutes. This treatment is more likely to injure the plants. Violets may be injured severely by the gas without the leaves being burned. This injury consists in a weakening of the plants which defers blooming for several weeks.

*Dormant nursery stock* may be fumigated with hydrocyanic acid gas in a tight box or fumigating-house made especially for the purpose. Fumigating-houses are built

of two thicknesses of matched boards with building-paper between, and are provided with a tight-fitting floor and ventilators. The stock should be reasonably dry to avoid injury, and should be piled loosely in the house to permit a free circulation of the gas. Use one ounce of potassium cyanide for each 100 cubic feet of space, and let the fumigation continue forty minutes to one hour.

A fumigating-house is shown in Fig. 1324 (from a bulletin on "The San José Scale," by A. E. Stene, of the Rhode Island State Board of Agriculture and College of Agriculture). It is a house or box as nearly airtight as possible. The floor should have a movable slat grating on which the plants may be laid, some distance from the ground, to allow of circulation of the gas. The house shown in the cut is 8 feet high in front and 6 feet in rear, and the larger room contains 980 cubic feet, requiring approximately ten ounces of cyanide. The other rooms allow of smaller quantities to be fumigated. The doors opening from the outside provide quick discharge of the air when fumigation is completed.

*Fumigation of citrus trees.*—In this case, the tree to be fumigated with the hydrocyanic acid gas is covered with an octagonal sheet tent (Fig. 1325) made of six and one-half ounce special drill or eight-ounce special army duck, and the gas is generated in the ordinary way beneath it. The tent is so marked that when in position it is an easy matter to determine the distance over the tent and the circumference at the ground. When these figures are known, the proper dosage may be obtained from the following chart, which has been prepared for a strength of one ounce of cyanide for each 100 cubic feet of space:

DISTANCE OVER, IN FEET.

Dosage chart for fumigating citrus trees with high-grade sodium cyanide (Bureau of Entomology, United States Department of Agriculture).

The top line of numbers, beginning at 16 and continuing to 68, represents the distance in feet around the bottom of the tent. The outer vertical columns of larger numbers running from 10 to 49 represent the distance in feet over the top of the tent. The number of ounces of cyanide to use for a tree of known dimensions is found in that square where the vertical column

headed by the distance around the tree intersects the horizontal line of figures corresponding to the distance over. For certain insects it is not advisable to use the full dosage schedule.

Sodium cyanide (NaCN) is coming into use as a substitute for potassium cyanide. When pure, this compound contains 53 per cent of cyanogen; that is, about 33 per cent more of cyanogen than is present in potassium cyanide. It is customary to indicate the strength of sodium cyanide in terms of potassium cyanide; that is, pure sodium cyanide is said to be 133 per cent pure. This means that 100 pounds of sodium cyanide will yield as much cyanogen as 133 pounds of potassium cyanide. For fumigation purposes, sodium cyanide should be at least 124 per cent pure and should not contain more than 1 per cent of common salt.

Because of the greater content of cyanogen of sodium cyanide, a smaller quantity is required. The chemicals should be combined in the following proportions: Sodium cyanide, one ounce; sulfuric acid, one and one-half fluid ounces; water, two ounces.

The following dosage schedule corresponds to the one given above for potassium cyanide:

1325. A fumigating tent (Morrill system).

often. It is always well to smoke through two consecutive days, for the insects which persist through the first treatment, being weak, will be killed by the second.

If the plants are wet, the smoke is more likely to scorch them. The smudge often injures flowers, as those of roses and chrysanthemums. In order to avoid this injury, the flowers should be covered with paper bags. Violet plants are very liable to injury.

Tobacco fumes can be more conveniently generated by burning strips of prepared nicotine paper, or by vaporizing a concentrated aqueous solution of nicotine over alcohol or special kerosene lamps.

Bisulfid of carbon is a thin liquid that volatilizes at a very low temperature, the vapor being very destructive to animal life. It is exceedingly inflammable, and should never be used near a lamp or fire. It is sometimes used for the control of certain root insects. It is poured into holes made around the infested plants, and these are then immediately

closed up causing the fumes to permeate the soil in all directions.

Against weevils infesting stored grain and seeds, carbon bisulfid is effective at the rate of five to eight pounds for each 1,000 cubic feet, provided the application is made while the temperature is not below 65° F. Make the bins as tight as possible. If bins are only single sheathed with common flooring use twenty to twenty-five pounds carbon bisulfid. Let the fumigation continue for at least twenty-four hours. Care should be taken not to apply carbon bisulfid when there is indication of heating in the grain.

C. R. CROSBY.  
ROBERT MATHESON.

Dosage chart for fumigating citrus trees with potassium cyanide (Bureau of Entomology, United States Department of Agriculture).

*Nicotine preparations.*—Tobacco is used in various ways in fumigating greenhouses. For smoking or smudging greenhouses, tobacco-stems are burned slowly. Best results are secured when a sheet-iron vessel made for the purpose is used, having holes in the bottom to supply draft. A quart of live coals is placed in the bottom of the vessel, and about a painful of tobacco-stems is laid on them. The stems should not blaze, but burn with a slow smudge. If they are slightly damp, better results are obtained. Some plants are injured by a very heavy smoke, and in order to avoid this injury, and also more effectually to destroy the insects, it is better to smoke rather lightly and

## Catalogue of insects.

**Abutilon.** **ABUTILON MOTH** (*Cosmophila erosa*).—A pale pea-green caterpillar striped with lemon-yellow often defoliates the plants in the southern states.

*Treatment.*—The young caterpillar may be killed by spraying with "Black Leaf 40" tobacco extract, one part in 650 parts water, adding soap to make the liquid spread and stick better.

**Acacia.** **COTTONY CUSHION SCALE.**—See *Citrus*.

**OLEANDER SCALE.**—See *Hedera*.

**RED SCALE.**—See *Citrus*.

**Acer.** **BOX-ELDER BUG** (*Leptocoris trivittatus*) is about  $\frac{1}{2}$  inch in length, dark gray in color marked with red. They congregate about box elder in great numbers, on the sap of which they feed. The young nymphs may be killed by spraying with ordinary contact insecticides.

**COTTONY MAPLE SCALE** (*Pulvinaria vitis*) is a brown, soft-bodied, scale insect,  $\frac{1}{2}$  inch in length. The eggs are laid beneath a conspicuous cottony mass which protrudes from under the scale. The eggs hatch during June and July, and the fertilized females hibernate on the smaller branches. There is one generation annually.

*Treatment.*—A stiff stream of water will dislodge many of the mature scales in June or July. The young scales may be killed with tobacco extract. The most effective treatment on maples is 15 per cent kerosene emulsion applied during the dormant season to kill the hibernating females.

**GREEN-STRIPED MAPLE WORM** (*Anisota rubicunda*) is a large, pale yellowish green caterpillar, striped with dark green, that occasionally defoliates the maple.

*Treatment.*—The young caterpillars may be controlled by spraying with arsenate of lead, four to eight pounds to one hundred gallons of water.

**PIGEON TREMEX** (*Tremex columba*) is a large four-winged fly having a wing expanse of  $2\frac{1}{2}$  inches. The abdomen ends in a prominent ovipositor. The larva, over 2 inches long when full-grown, burrows in the wood, seriously injuring the tree when abundant. Vigorous trees usually overcome the attack.

**PLANT-LICE.**—Several species are occasionally injurious.

*Treatment.*—"Black Leaf 40" tobacco extract, three-fourths of a pint to one hundred gallons of water, adding four pounds of soap, is an efficient remedy.

**SUGAR-MAPLE BORER** (*Plagionotus speciosus*) is very destructive to hard maples. The parent beetle is about an inch long, black, brilliantly marked and banded with yellow. The larva is a large borer about 2 inches in length when mature. They burrow mostly in the sapwood, several often girdling and killing a tree. It is a difficult matter to prevent this injury.

*Treatment.*—Digging out the borers is the only remedy known.

**WOOLLY MAPLE-LEAF SCALE** (*Phenacoccus acericola*) is a soft-bodied woolly-covered insect about  $\frac{1}{4}$  inch long, found on the under side of the leaves. There are two or three generations a year. They hibernate as young on the bark of the trunk and branches.

*Treatment.*—Winter applications of whale-oil soap, one pound in one gallon of water, have given the best results.

**Æsculus.** **TUSsock-MOTH.**—See *Apple*.

**Agave.** **OLEANDER SCALE.**—See *Hedera*.

**RED SCALE.**—See *Citrus*.

**Alder.** **ALDER BLIGHT APHIS** (*Pemphigus tessellata*) occurs in colonies on the branches and appears as conspicuous white, woolly masses.

*Treatment.*—They may be dislodged by a stiff stream of water or may be killed by spraying with kerosene emulsion.

**SAW-FLY LEAF-MINER** (*Kaliopsisphinga dohrnii*) feeds between the upper and lower layers of the leaves, causing large blotch mines.

No remedy known.

**Allamanda.** **CITRUS WHITE FLY.**—See *Citrus*.

**Almond.** **BLACK SCALE.**—See *Citrus*.

**CLOVER MITE.**—See *Peach*.

**COTTONY CUSHION SCALE.**—See *Citrus*.

**PEAR THRIPS.**—See *Pear*.

**SAN JOSÉ SCALE.**—See *Apple*.

**Aloe.** **OLEANDER SCALE.**—See *Hedera*.

**Amaryllis.** **NARCISSE BULB-FLY.**—See *Narcissus*.

**Ampelopsis.** **MYRON SPHINX** (*Ampelophaga myron*).—Large, green or brown, smooth caterpillars occasionally defoliate the vines.

*Treatment.*—Hand-picking.

**Annona.** **FLORIDA WAX SCALE.**—See *Citrus*.

**Anthurium.** **FLORIDA WAX SCALE.**—See *Citrus*.

**Apple.** **APHIDS OR PLANT-LICE.**—There are three species which commonly attack the opening buds and leaves of apple,—the leaf aphid (*Aphis pomi*), rosy aphid (*Aphis sorbi*) and bud aphid (*Siphocoryne avenae*).

*Treatment.*—These small, soft-bodied insects may be controlled by thorough spraying with "Black Leaf 40" tobacco extract, three-fourths of a pint, in one-hundred gallons of water, adding four pounds of soap. Make the application before the leaves curl.

**APPLE-CURCULIO** (*Anthonomus quadrigibbus*).—A soft, white grub, about  $\frac{1}{2}$  inch long, living in the fruit.

*Treatment.*—Clean cultivation. Rake the small apples that drop early out into the sun where they will dry up.

## CATALOGUE OF INSECTS, continued.

**APPLE FLEA-BEETLE** (*Graptodera foliacea*).—Brassy, green beetle,  $\frac{1}{2}$  inch or less long, feeding upon leaves.

*Treatment.*—Arsenicals. Lime-sulfur or bordeaux mixture as a repellent.

**APPLE LEAF-HOPPER** (*Empoasca mali*).—A slender pale yellowish green bug; the nymphs are pale greenish and usually found on the under side of the leaves. The winter eggs are laid in blisters under the bark of the smaller branches; summer eggs, in the leaf veins and petioles. Four generations annually. The insect feeds by extracting the juices from the leaves, causing them to turn pale and curl. It is most injurious to nursery stock.

*Treatment.*—The young nymphs may be killed by spraying with "Black Leaf 40" tobacco extract, three-fourths of a pint in one hundred gallons of water, adding three to four pounds of soap. Nurserymen often catch the adults by the use of sticky shields.

**APPLE LEAF-ROLLER** (*Archips argyrospila*).—A green caterpillar with a black head, 1 inch or less in length when mature, attacks the opening buds rolling and webbing together the leaves, flowers and young fruit into a nest. Holes are eaten in the young apples, deforming them. Eggs are laid in June in small, flat masses on the bark and are covered with a smooth varnish-like coating. They do not hatch till the following spring.

*Treatment.*—To kill eggs spray with miscible oil, one gallon in fifteen gallons of water, making the application as late as possible before the buds open. If the eggs have been neglected, recourse must be had to arsenate of lead, six pounds in one hundred gallons of water. Apply before the blossoms open.

**APPLE MAGGOT** (*Rhagoletis pomonella*).—A white maggot that tunnels apples through and through, causing decay and falling of the fruit. The parent flies appear the latter part of June and early July and insert the eggs under the skin of the fruit. Hibernation takes place in small puparia just below the surface of the soil. Sweet and subacid varieties are most susceptible, but others are sometimes attacked.

*Treatment.*—Clean cultivation. Spray when flies appear with arsenate of lead, four pounds in one hundred gallons of water. The addition of two or three gallons of molasses is supposed to render the poison more attractive to the flies.

**BROWN-TAIL MOTH** (*Euproctis chrysorrhæa*).—This highly destructive European insect was introduced near Boston a number of years ago, and is now rapidly spreading over New England. The snow-white moths, with a large tuft of brown hairs at the tip of the abdomen, appear in July and deposit eggs on the leaves in elongate masses covered with brown hairs from the body of the female. The caterpillars become only partly grown the first season, and hibernate in conspicuous nests, 3 or 4 inches long, at the tips of the branches. The black-bodied caterpillars, clothed with rather long, brownish, stinging hairs, complete their growth the next spring, feeding ravenously on the tender foliage and causing great damage in orchards, parks, and forests.

*Treatment.*—Cut out and burn all winter nests before the buds start. In the spring, spray with arsenate of lead, as recommended for the gipsy-moth. Prevent the ascent of caterpillars from other trees by banding the trunks with tanglefoot. Keep the bands fresh by combing the surface every few days.

**BUD-MOTH** (*Tmetocera ocellana*).—The small brown caterpillars with black heads burrow into the buds, feeding on the opening leaves and flowers and web them together.

*Treatment.*—Spray with arsenate of lead, four pounds in one hundred gallons of water, just as the blossoms show pink, and again as the last of the petals are falling.

**CANKER-WORM, FALL** (*Alsophila pometaria*).—Wingless female moths usually emerge from the ground in late autumn, crawl up the trees and deposit their eggs on the smaller branches. The eggs hatch in April or May and the blackish yellow-striped, looping caterpillars defoliate the trees.

*Treatment.*—Band tree trunks in the fall with tanglefoot or cotton batting to prevent ascent of moths. The young canker-worms may be killed by spraying with arsenate of lead, six pounds to one hundred gallons of water.

**CANKER-WORM, SPRING** (*Paleacrita vernata*).—Habits similar to the fall canker-worm, but the moths emerge in March and April. Caterpillars are distinguished by having only two pairs of prolegs.

*Treatment.*—Same as for fall canker-worm except the bands should be applied in early spring.

**CASE-BEARERS.**—The pistol-case-bearer (*Coleophora malivorella*) and the cigar-case-bearer (*C. fletcherella*).—The small caterpillars live in pistol or cigar-shaped cases, about  $\frac{1}{4}$  inch long, that they carry around with them. They appear in spring on the opening buds at the same time as the bud-moth, and may be controlled by the same means.

**CODLIN-MOTH** (*Carpocapsa pomonella*).—This is the pinkish caterpillar which causes a large proportion of wormy apples. The eggs are laid by a small moth on the leaves and the skin of the fruit. Most of the caterpillars enter the apple at the blossom end. When the petals fall, the calyx is open, and this is the time to spray. The calyx soon closes, and keeps the poison inside ready for the young caterpillars' first meal. After the calyx has closed, it is too late to spray effectively. The caterpillars become full-grown in July and August, leave the fruit, crawl down on the trunk, and there most of them spin cocoons under the loose bark. In most parts of the country there are two broods annually.

## CATALOGUE OF INSECTS, continued.

**Treatment.**—As the last of the petals are falling, spray with four pounds arsenate of lead in one hundred gallons of water, using a stiff spray to force it into the blossom end of the apple. Repeat the application three weeks later.

**FALL WEB-WORM** (*Hyphantria cunea*).—Hairy larva, about an inch long, varying from gray to pale yellow or bluish black, feeding upon the leaves of many trees, in tents or webs.

**Treatment.**—Destroy by burning the webs, or removing them and crushing the larvæ. Spray with arsenicals.

**FLAT-HEADED BORER** (*Chrysobothris femorata*).—Larva about an inch long, flesh-colored, the second segment ("head") greatly enlarged; boring under the bark and sometimes into the wood. They are readily located in late summer or fall by the dead and sunken patches of bark.

**Preventive.**—Soap and carbolic acid washes applied from May to July. Keep trees vigorous.

**GREEN FRUIT-WORMS** (*Xylina* sp.).—Yellowish or apple-green caterpillars, striped with cream-color, 1 to 1½ inches in length when mature, attack the opening leaves and blossoms and eat holes in the developing fruit. The parent moths emerge from hibernation in early spring and lay their eggs on the smaller branches. One brood annually.

**Treatment.**—Thorough and repeated spraying with arsenate of lead, six pounds in one hundred gallons of water, will kill many of the young caterpillars. Make the application when blossom clusters appear.

**GYPSEY MOTH** (*Porthetria dispar*).—The full-grown caterpillar is about 2 inches long, dark gray in ground-color with eleven pairs of prominent tubercles on the back, the first five pairs blue, the last six dark red. They become full-grown about the first of July. They pupate in slight cocoons. The moths emerge in seven to seventeen days. The male has a light brown body, wings yellowish brown, and each front wing is crossed by four wavy dark brown lines. In the female the body is light buff and the wings grayish white. The dark markings on the front wings are similar to those of the male. The females do not fly, but each lays its eggs in a mass about an inch in length covered with hairs from its body. Hibernation takes place in the egg stage. The eggs hatch just as the buds are bursting.

**Treatment.**—Kill the eggs by saturating the masses with crude coal-tar creosote, to which a little lamp-black has been added as a marker. When the young caterpillars hatch, spray the trees with arsenate of lead, ten pounds in one hundred gallons of water. When the caterpillars are half-grown, use thirteen to fifteen pounds of lead arsenate. Full-grown caterpillars are very resistant to poisons. Band the tree trunks with tanglefoot to prevent the ascent of wandering caterpillars.

**LEAF-BLISTER MITE.**—See *Pear*.

**LEAF-CRUMPLER** (*Mineola indigenella*).—Reddish brown caterpillars that live in slender, horn-shaped cases and feed on the tender leaves. They hibernate as partly grown larvæ and attack the opening buds the following spring. They usually live in a nest of several leaves fastened together with silk.

**Treatment.**—Gather the nests and burn them. Arsenicals when the buds open.

**LESSER APPLE-WORM** (*Ecnarmonia prunivora*).—Similar to the codlin-moth, but larvæ often feed just under the skin of the fruit, causing blotched areas.

**Treatment.**—As for codlin-moth.

**OYSTER-SHELL SCALE** (*Lepidosaphes ulmi*).—This is an elongate scale (sometimes called bark-louse), ½ inch in length, resembling an oyster-shell in shape and often incrusting the bark. It hibernates as minute white eggs under the old scales. The eggs hatch during the latter part of May or in June, the date depending on the season. After they hatch, the young may be seen as tiny whitish lice crawling about on the bark. When these young appear, spray with kerosene emulsion, diluted with six parts of water, or whale-oil, or any good soap, one pound in four or five gallons of water. Where trees are regularly sprayed with lime-sulfur, as for the San José scale or blister mite, the oyster-shell scale is usually controlled.

**PALMER WORM** (*Ypsolophus pometellus*).—The brownish green, white-striped caterpillars, ½ inch in length when mature, skeletonize the tender foliage in June and eat holes in the young apples. There is only one brood a year.

**Treatment.**—Spray with arsenate of lead, four pounds in one hundred gallons of water when the caterpillars first appear.

**PLUM-CURCULIO** (*Conotrachelus nenuphar*).—A snout-beetle that deforms the fruit by its characteristic feeding and egg-laying punctures. The grubs develop in the fruit and cause it to fall.

**Treatment.**—Spraying with arsenate of lead, as for codlin-moth, whenever it can be applied with a fungicide so as not to increase expense, will help to control the trouble. Thorough superficial tillage of the surface of soil during July and August will kill many of the pupæ, and is recommended. For treatment on plum, see under *Plum*.

**RED BUGS** (*Heloroodylus malinus* and *Lygidea mendax*).—The winter is passed as eggs inserted in the smaller branches. The brilliant red nymphs appear as the buds open and feed on the foliage for a time. Then they puncture the newly set apples causing one of three things: some drop, some dry up and remain on trees till next spring, and others mature as knotty, misshapen, worthless fruit. One generation a year.

**Treatment.**—The young nymphs may be killed by thorough spraying with "Black Leaf 40" tobacco extract, one pint in one hundred gallons water, adding four pounds of soap, (1) when blossoms show pink, (2) when the last of the petals are falling.

## CATALOGUE OF INSECTS, continued.

**RED-HUMPED APPLE CATERPILLAR** (*Schizeura concinna*).—These red-headed, black-and-yellow-striped caterpillars with a red hump on the fourth segment often attract attention in August and September by feeding in colonies on the ends of the branches.

**Treatment.**—Spray for the young caterpillars with arsenate of lead, four pounds in one hundred gallons of water. As they are most troublesome on newly planted trees the older caterpillars may be shaken to the ground and crushed under foot.

**RIBBED COCOON-MAKER** (*Bucculatrix pomifoliella*).—A minute yellow or green larva feeding upon the upper surface of the leaves, causing the lower surface to turn brown. The cocoons are white and slender, and are laid side by side upon the under side of twigs, where they are conspicuous in winter.

**Treatment.**—Lime-sulfur while tree is dormant. Arsenicals for the larvæ in summer.

**ROSE-CHAFER.**—See *Grape*.

**ROUND-HEADED BORER** (*Saperda candida*).—A yellowish white grub with dark brown head, about 1 inch long when mature. It is said to remain in the larval state three years. The parent beetle is silvery white on the head and beneath; the thorax and wing-covers are light brown; two silvery white stripes extend from the head to the tip of the wing-covers. The eggs are laid in slits in the bark, mostly in June.

**Preventive.**—Keep the beetles from laying eggs by spraying the trunks several times during the spring and summer with kerosene emulsion or by coating them with an alkaline wash made from soap, caustic potash, and carbolic acid. Tared paper tree-protectors well tied at the top, or wire mosquito-netting protectors closed at the top and encircling the trunk so loosely that the beetles cannot reach the bark, are effective in preventing egg-laying. Practise clean cultivation, and do not let water sprouts or other rank vegetation encircle the base of the tree.

**Remedial.**—Dig out the borers whenever they can be located by discolored bark or by the sawdust thrown out of the burrow.

**SAN JOSÉ SCALE** (*Aspidiotus perniciosus*).—This scale is nearly circular in outline and about the size of a pinhead. When abundant it forms a crust on the branches, and causes small red spots on the fruit. It multiplies with marvelous rapidity, there being three or four broods annually, and each mother scale may give birth to several hundred young. The young are born alive, and breeding continues until late autumn, when all stages are killed by the cold weather, except the tiny, half-grown, black scales, many of which hibernate safely.

**Treatment.**—Spray thoroughly in the fall after the leaves drop, or early in the spring before growth begins, with lime-sulfur wash, one gallon in eight gallons of water, or miscible oil, one gallon in fifteen gallons of water. When badly infested, make two applications, one in the fall and another in the spring. In case of large, old trees, 25 per cent crude-oil emulsion should be applied just as the buds are swelling.

**SCURFY SCALE** (*Chionaspis furfurus*).—This whitish, pear-shaped scale, about ½ inch in length, often incrusts the bark, giving it a scurfy appearance. It hibernates as purplish eggs under the old scales.

**Treatment.**—Spray as recommended for oyster-shell scale.

**TENT-CATERPILLARS** (*Malacosoma americana* and *M. dissimilis*).—Larvæ nearly 2 inches long, spotted and striped with yellow, white, and black; feeding upon the leaves. They congregate in tents or in clusters on the bark at night and in cool weather, and forage out upon the branches during the day.

**Treatment.**—Arsenicals, as for codlin-moth. Burn out nests with torch, or cut them out and crush the larvæ. Pick off egg masses from twigs during winter and spring.

**TUSsock-MOTH** (*Hemerocampa leucostigma*).—A handsome, red-headed, yellow and black tufted caterpillar, about an inch long, which devours the leaves and sometimes eats into the fruit.

**Remedial.**—Collect the frothy egg-masses in fall and winter and band the trees to prevent a reinfestation by migrating caterpillars. Spray with arsenicals as for codlin-moth, taking care to cover the under side of the leaves.

**TWIG-BORER** (*Schistoceros hamatus*).—Beetle, ¾ inch long, cylindrical and dark brown, boring into twigs of apple, pear, and other trees. The beetle enters just above a bud.

**Treatment.**—Burn the twigs. The early stages are passed in dying wood, such as prunings, diseased canes, and in upturned roots. Burn such rubbish, and thus destroy their breeding-places. This is also a grape pest.

**TWIG-GIRDLER** (*Oncideres cingulatus*).—Small branches are often girdled by a handsome ash-sprinkled reddish brown beetle, about ½ inch in length. The girdled twigs soon fall and the grubs develop in the fallen branches.

**Treatment.**—Collect and burn all fallen branches.

**WOOLLY APHIS** (*Schizoneura lanigera*).—Small reddish brown plant-lice covered with a conspicuous mass of white, waxy fibers, found on the branches, sprouts, trunks and roots.

**Treatment.**—For the form above ground drench the infested parts with 15 per cent kerosene emulsion; for the underground form remove the earth beneath the tree to a depth of 3 inches, and apply 10 per cent kerosene emulsion liberally, and replace the earth. In the case of nursery stock the emulsion may be applied in a shallow furrow close to the row. Do not set infested trees.

**YELLOW-NECKED APPLE CATERPILLARS** (*Datana ministra*).—Apple branches are often defoliated in late summer by colonies of black- and yellow-striped caterpillars about 2 inches in length when mature.

**Treatment.**—Same as for Red-humped Caterpillar, which see.

## CATALOGUE OF INSECTS, continued.

**Apricot.** BARK BEETLE.—See *Peach*.

BLACK SCALE.—See *Citrus*.

CANKER-WORMS.—See *Apple*.

CLOVER MITE.—See *Peach*.

COTTONY CUSHION SCALE.—See *Citrus*.

EUROPEAN FRUIT LECANIUM.—See *Plum*.

FROSTED SCALE (*Eulecanium prunosum*).—A large soft-bodied scale,  $\frac{1}{2}$  inch in length, hemispherical in shape with a frost-like covering of wax.

*Treatment*.—Kerosene or distillate emulsion while the trees are dormant.

PEACH TREE-BORERS.—See *Peach*.

PEAR THRIPS.—See *Pear*.

PLUM-CURCULIO.—See *Plum*.

**Aquilegia.** COLUMBINE BORER (*Papaipema purpurifascia*).—The full-grown caterpillar measures  $1\frac{1}{4}$  inches in length, salmon-pink in color with three narrow stripes visible from above, the two lateral ones broadly interrupted in the middle. It bores in the stems near the base.

*Treatment*.—Dig out and destroy caterpillars.

**Artichoke.** STEM MAGGOT (*Straussia longipennis*).—A small yellowish maggot boring in the pith of the stems. The adult are two-winged yellowish flies with banded wings.

*Treatment*.—Encourage growth; vigorous plants outlive injury.

**Asparagus.** COMMON ASPARAGUS-BEETLE (*Crioceris asparagi*).—Beetle, less than  $\frac{1}{4}$  inch in length, yellow, red, and shining black, with conspicuous ornamentation, feeding upon the tender shoots. Larva feeds upon the leaves and tender bark.

*Treatment*.—Freshly slaked lime dusted on before the dew has disappeared in the morning. Poultry. Cut down all plants in early spring to force the beetles to deposit their eggs upon the new shoots, which are then cut every few days before the eggs hatch; or leave a row or so around the field as a lure for the beetles where they may be killed with arsenicals.

TWELVE-SPOTTED ASPARAGUS-BEETLE (*Crioceris 12-punctata*).—Similar to the last, but with twelve spots on the wing-covers.

*Treatment*.—Similar to that used above, except that the grubs cannot be destroyed by lime, since they live within the berry.

ASPARGUS MINER (*Agromyza simplex*).—A maggot mining under the skin near the base of the plant.

*Treatment*.—Leave a few volunteer plants as a trap in which the fly will deposit her eggs. Pull and burn these plants in late June and early July. The flies may be killed before ovipositing with sweetened arsenate of lead.

**Aspidistra.** FLORIDA RED SCALE.—See *Citrus*.

**Aster.** BLISTER BEETLES.—Large, black, grayish or striped beetles that feed on the flowers. The larvæ in general feed on grass-hopper eggs.

*Treatment*.—Hand-picking.

TARNISHED PLANT-BUG (*Lygus pratensis*).—An active bronzy brown sucking bug  $\frac{1}{2}$  inch long, mottled with various shades of yellowish, that stunts the terminal buds by its feeding punctures and also injures the flower-buds so that they either do not open or produce imperfect flowers. Injured plants are dwarfed and stunted.

*Treatment*.—No satisfactory control measures are known. Plants grown in shade are less liable to injury.

ROOT-LOUSE (*Aphis maidiradicis*).—Small bluish green plant-lice infesting the roots, causing the plants to turn yellow and sickly.

*Treatment*.—Mix tobacco dust into the soil around the plants when transplanting.

WHITE GRUBS.—See *Corn*.

**Aucuba.** THE YELLOW SCALE.—See *Citrus*.

**Avocado.** LEAF-ROLLER (*Amorbia emigratella*).—A yellowish green caterpillar striped with pinkish brown, about 1 inch long when mature, rolls the leaves and eats small holes in the fruit, rendering it unfit for sale.

*Treatment*.—Arsenate of lead when the caterpillars appear.

MEALY-BUG (*Dactylopius nipæ*).—A small unarmored scale with white mealy covering.

*Treatment*.—Kerosene emulsion, one part to ten parts water.

**Bamboo.** COTTONY BAMBOO SCALE (*Antonina crawi*).—Small purplish red scales  $\frac{1}{2}$  to  $\frac{1}{4}$  inch in length, covered with a dense cottony coating; often  $\frac{1}{2}$  inch in diameter. They collect in large numbers in the crotches and leaf-axils.

*Treatment*.—Repeated applications of kerosene emulsion.

PLANT LOUSE (*Myzocallis arundincolens*).—Small yellowish lice which collect in large numbers on the under surface of the leaves.

*Treatment*.—Contact sprays.

**Banana.** BANANA WEEVIL (*Sphenophorus sordidus*).—A small grub boring in the stems.

FLORIDA RED SCALE.—See *Citrus*.

MEALY-BUG (*Ceropota yuccæ*).—Soft scales closely resembling the common mealy-bug (*Pseudococcus*).

*Treatment*.—Kerosene emulsion.

**Bean.** BEAN LADY-BIRD (*Epilachna corrupta*).—A light yellowish brown lady-bird beetle, with four black spots on each wing-cover, attacks and devours all parts of the bean plant. The larva, which is yellow and covered with stout branched spines, also feeds on the bean.

*Treatment*.—Arsenate of lead or kerosene emulsion.

## CATALOGUE OF INSECTS, continued.

**BEAN LEAF-BEETLE** (*Cerotoma trifurcata*).—A pale yellow beetle  $\frac{1}{2}$  inch in length, with black markings on the wing-covers, often eats round holes in the leaves. The larvæ feed on the roots and main stems of the plants.

*Treatment*.—Arsenate of lead as soon as the beetles appear.

**BEAN-WEEVIL** (*Bruchus obtectus*).—Closely resembles the pea-weevil, which see for description and remedies. Holding over the seed will be of no value with this insect.

**CORN-EAR WORM**.—See *Corn*.

**CUTWORM**.—See *Corn*.

**PEA APHIS**.—See *Pea*.

**SEED-CORN MAGGOT** (*Pegomya fusciceps*).—A maggot attacking germinating seeds and roots of young plants.

*Treatment*.—Avoid stable manure; practise crop-rotation. In the garden, use sand moistened with kerosene around the plants to keep the flies from laying the eggs.

**Beet.** BEET APHIS (*Pemphigus betæ*).—A root-infesting plant-louse locally abundant in certain western states.

*Treatment*.—Rotation of crops.

**BEET LEAF-HOPPER** (*Eutettix tenella*).—A small, pale yellowish green leaf-hopper punctures the leaves, causing the disease, curly top. Present in the western states.

*Treatment*.—No satisfactory treatment known.

**BLISTER BEETLES**.—See *Aster*.

**CUTWORMS**.—See *Corn*.

**FALSE CHINCH BUG** (*Nysius angustatus* var. *minutus*).—Small grayish brown bugs,  $\frac{1}{8}$  inch in length. Destructive to sugar beets grown for seed.

*Control*.—Contact insecticides; clean cultivation.

**GRASSHOPPERS**.—See *Corn*.

**LEAF-MINER**.—See *Spinach*.

**LARGER BEET LEAF-BEETLE** (*Monoxia puncticollis*).—A dull brown beetle with striped wing-covers. Both larvæ and adults feed on the sugar beet, often in immense numbers.

*Treatment*.—Same as for *Flea-Beetles*. See *Potato*.

**FLEA-BEETLE**.—See *Potato*.

**WESTERN BEET BEETLE** (*Monoxia consputa*).—A beetle closely allied to the larger beet leaf-beetle, feeding on the leaves, leaving only the veins.

*Treatment*.—Same as for *Flea-Beetles*. See *Potato*.

**BEET ARMY WORM** (*Laphygma exiqua*).—A large caterpillar about  $1\frac{1}{4}$  inches long when mature, olivaceous to greenish in color, broadly striped with lighter green; defoliates the plants.

*Treatment*.—See *Army Worm, Corn*.

**BEET WEB-WORM** (*Loxostege sticticalis*).—Pale yellowish green caterpillars striped with lighter green, about  $\frac{1}{4}$  inch long, frequently defoliate the plants in certain regions.

*Treatment*.—Destroy all weeds. Spray with arsenate of lead.

**Begonia.** GREENHOUSE THRIPS.—See *Citrus*.

GREENHOUSE WHITE-FLY.—See *Tomato*.

MEALY-BUGS.—See *Citrus*.

WHITE-FLY.—See *Citrus*.

**Berberis.** BARBERRY PLANT-LOUSE (*Rhopalosiphium berberidis*).—Small, greenish yellow lice attacking the leaves and young growth.

*Treatment*.—Tobacco extract or kerosene emulsion.

**Betula.** BIRCH APHIS (*Callipterus betulecoleus*).—A small, yellowish plant-louse occasionally abundant on the under side of birch foliage (cut-leaf varieties).

*Treatment*.—'Black Leaf 40' tobacco extract three-fourths of a pint to one hundred gallons of water.

**BIRCH LEAF BUCCULATRIX** (*Bucculatrix canadensisella*).—Small, whitish larvæ skeletonizing the leaves.

*Treatment*.—Arsenate of lead, six pounds in one hundred gallons water.

**BRONZE BIRCH BORER** (*Agrilus anxius*).—Slender, flattened yellowish white grubs,  $\frac{3}{4}$  inch long when full-grown, burrow under the bark on all parts of the tree. The top branch usually dies first and is the first indication that the tree is infested.

*Treatment*.—Cut down and burn all infested trees immediately to prevent spread to other trees.

**FROSTED SCALE**.—See *Apricot*. Occurs in California on birch.

**OYSTER-SHELL SCALE**.—See *Apple*.

**Bignonia.** HEMISPHERICAL SCALE.—See *Citrus*.

MEALY-BUGS.—See *Citrus*.

**Billbergia.** PINEAPPLE SCALE.—See *Pineapple*.

**Blackberry.**—See *Bramble Fruits*.

**Bramble Fruits.** BLACKBERRY LEAF-MINER (*Metellus rubi*).—A greenish white larva with brown markings,  $\frac{1}{2}$  inch in length when full-grown, causing blotch mines in the leaves.

*Treatment*.—No satisfactory treatment known.

**CANE-BORER** (*Obera bimaculata*).—Beetle, black, small, and slim; making two girdles about an inch apart near the tip of the cane, in June, and laying an egg just above the lower girdle; the larva, attaining the length of nearly an inch, bores down the cane. Also in blackberry.

*Remedy*.—As soon as the tip of the cane wilts, cut it off below the lower girdle and burn it.

**RASPBERRY BEETLE** (*Bythorus unicolor*).—A light brown beetle one-seventh inch long feeds on the opening leaves and blossoms. The small white grub feeds between the berry and receptacle of red raspberries.

**RASPBERRY CANE MAGGOT** (*Phorbia rubivora*).—Small, white maggot which burrows in the new canes and girdles the shoot. The eggs are laid by a fly in April or May.

## CATALOGUE OF INSECTS, continued.

*Treatment*.—Pull up or cut off canes several inches below the girdle and burn them.

**RASPBERRY HORNTAIL** (*Hartigia abdominalis*).—A whitish larva, about 1 inch in length when mature; when young it burrows under the bark, girdling the tip. It then tunnels out the pith.

*Treatment*.—Cut off infested canes when wilting is observed.

**RASPBERRY ROOT-BORER** (*Bembecia marginata*).—Larva about 1 inch long, boring in the roots and the lower parts of the cane, remaining in the root over winter.

*Remedy*.—Dig out the borers. Destroy wild berry bushes.

**RASPBERRY SAW-FLY** (*Monophadnus rubi*).—Larva about  $\frac{3}{4}$  inch long, green, feeding upon the leaves.

*Remedies*.—Hellebore; arsenicals, after fruiting.

**RED-NECKED CANE-BORER** (*Agrilus ruficollis*).—A yellowish white flattened grub,  $\frac{3}{4}$  inch in length when mature, burrows in the canes causing swellings or galls characterized by the splitting of the bark. The parent beetle is  $\frac{1}{2}$  inch in length, black, with thorax or "neck" reddish.

*Treatment*.—Cut out and burn all infested canes.

**RED-SPIDER**.—See *Peach*. Do not use lime-sulfur on raspberry foliage.

**TREE-CHICKET** (*Ecanthus nigricornis*).—Small and whitish cricket-like insect, puncturing canes for 2 or 3 inches, and depositing eggs in the punctures.

*Remedy*.—Burn all infested canes in winter or very early spring.

**Brassica**.—See *Cabbage*.

**Brussels Sprouts**.—See *Cabbage*.

**Buxus**. **OLEANDER SCALE**.—See *Hedera*.

**Cabbage**. **CABBAGE APHIS** (*Aphis brassicæ*).—These small, mealy plant-lice are especially troublesome during cool, dry seasons, when their natural enemies are less active.

*Treatment*.—Thorough spraying with "Black Leaf 40" tobacco extract, three-fourths of a pint in one hundred gallons water, adding four or five pounds of soap.

**CABBAGE-LOOPER** (*Antographa brassicæ*).—A pale green looping caterpillar, striped with lighter lines, over 1 inch in length when mature. Especially destructive to late cauliflower.

*Treatment*.—Very difficult to poison. Some growers dust the plants with pure paris green, using a blower.

**CABBAGE MAGGOT** (*Pegomya brassicæ*).—A small white maggot, the larva of a small fly, eating into the crown and roots of young cabbage, cauliflower, radish, and turnip plants.

*Treatment*.—Carbolic acid emulsion diluted with thirty parts of water, applied the day following the transplanting of the cabbage plants, and repeated once a week for several applications. Remove a little earth from about the plants, and spray on the emulsion forcibly. Better results may be secured by using tightly fitting cards cut from tarred paper. In seed-beds, protect the plants by surrounding the bed with boards 1 foot wide placed on edge, across which a tight cover of cheese cloth is stretched.

**CABBAGE-WORM** or **CABBAGE-BUTTERFLY** (*Pontia rapæ*).—The green caterpillars hatch from eggs laid by the common white butterfly. There are several broods every season.

*Treatment*.—If plants are not heading, spray with kerosene emulsion or with paris green to which the sticker has been added. If heading, apply hellebore.

**CUTWORMS**.—See *Corn*.

**DIAMOND-BACK MOTH** (*Plutella maculipennis*).—A pale green, active caterpillar, about  $\frac{1}{2}$  inch in length when mature, feeds on the under sides of the leaves. Pupates in an open-work silken cocoon on the leaves. Destructive to late cauliflower.

*Treatment*.—Same as for cabbage looper.

**FLEA-BEETLES**.—See *Potato*.

**HARLEQUIN CABBAGE-BUG** (*Murgantia histrionica*).—Bug about  $\frac{1}{2}$  inch long, gaudily colored with orange dots and stripes over a blue-black ground, feeding upon cabbage; two to six broods.

*Treatment*.—Hand-picking. Place blocks about the patch, and the bugs will collect under them. In the fall make small piles of the rubbish in the patch, and burn them at the approach of winter. Practice clean culture. Destroy all cabbage stalks and other cruciferous plants in fall. Early in the spring, plant a trap crop of mustard, radish, rape, or kale. When the overwintering bugs congregate on these plants, destroy them with pure kerosene or by hand.

**Cactus**. **MEALY-BUGS**.—See *Citrus*.

**Cactus**. *Chelinidea vittiger*.—A yellowish bug resembling the common squash stink bug (*Anasa tristis*), feeding on the joints of opuntia, causing small circular discolored areas and destruction of the plants.

*Treatment*.—Destroy young with gasoline torch. In winter, burn trash in which adults are hibernating.

**COTTONY COCHINEAL INSECT** (*Dactylopius confusus*).—A scale insect covered with large flocculent masses of pure white wax.

*Control*.—Usually kept in check by its predaceous enemies. *Melittara juncotinella*.—Large indigo-blue (young), or conspicuously banded (last stage) larvae living within the joints of opuntia, causing tumor-like swellings.

*Control*.—Burn injured joints with gasoline torch.

*Mimorista flavidissimilis*.—Yellowish caterpillars burrowing in the young joints, thus destroying new growth. Their presence is indicated by exuding sap.

*Treatment*.—Powdered arsenate of lead dusted on the young growth early in the season.

*Narnia pallidicornis*.—Brownish yellow bugs about  $\frac{3}{4}$  inch in length injuring the fruit.

## CATALOGUE OF INSECTS, continued.

*Control*.—Destroy the gregarious bugs with the gasoline torch.

*Opuntia longicornis* (*Moneilema* sp.).—Shining, black, wingless beetles  $\frac{3}{4}$  to 1 inch in length. The larvae burrow in the main stems and older joints of the prickly pear.

*Control*.—Hand-picking the beetles; burning infested stems; spraying with arsenate of lead.

**Carnation**. **CARNATION MITE** (*Pediculopsis graminum*).—A minute mite found in the buds and instrumental in transmitting the bud-rot disease.

*Treatment*.—Gather and burn all infested buds.

**GREEN PLANT-LOUSE** (*Myzus persicæ*).—Small greenish plant-lice infesting the terminal branches.

*Treatment*.—Fumigation with hydrocyanic acid gas or tobacco.

**Carrot**. **CARROT BEETLE** (*Ligyrus gibbosus*).—A reddish brown beetle  $\frac{1}{2}$  inch or more long, which attacks the young plants. The larva lives in the ground, where it feeds on humus.

*Preventive*.—Crop-rotation and other remedies for white grub. See under *Corn*.

**CARROT RUST FLY**.—See *Celery*.

**PARSNIP LEAF-MINER**.—See *Parsnip*.

**PARSNIP PLANT-LOUSE**.—See *Parsnip*.

**PARSNIP WEB-WORM**.—See *Parsnip*.

**Carya**.—See *Hickory*.

**Castanea**.—See *Chestnut*.

**Catalpa**. **CATALPA-MIDGE** (*Cecidomyia catalpæ*).—Small yellowish-maggots, scarcely  $\frac{1}{2}$  inch in length when mature, attacking the seeds, terminal buds, ends of branches and leaves, deforming them.

*Treatment*.—Plow in early fall or late spring to destroy pupæ in nurseries.

**CATALPA SPHINX** (*Sphinx catalpæ*).—A sulfur-yellow caterpillar with black head and a broad black stripe down the back, about 2  $\frac{1}{2}$  inches in length when mature, defoliates the trees. Several broods a season.

*Treatment*.—Arsenate of lead when the caterpillars are small. Hand-picking later.

**Cauliflower**.—See *Cabbage*.

**Ceanothus**. **CITRUS MEALY-BUG**.—See *Citrus*.

**MEALY-BUG**.—See *Banana*.

**OYSTER-SHELL SCALE**.—See *Apple*.

**Celery**. **CARROT RUST-FLY** (*Psila rosæ*).—Minute whitish yellow maggots infesting the roots and stunting the plants.

*Preventive*.—Late sowing and rotation of crops. Celery or carrots should not follow each other.

**CELERY CATERPILLAR** (*Papilio polyxenes*).—A large green caterpillar, ringed with black and spotted with yellow, which feeds on the leaves.

*Treatment*.—Hand-picking as soon as observed.

**CELERY LEAF-TYER** (*Phlyctantia ferrugalis*).—A greenish caterpillar, feeding on the under side of the leaves.

*Treatment*.—Spray with arsenicals while the larvae are still young.

**CELERY LOOPER** (*Antographa falcigera*).—A greenish looping caterpillar with white stripes, about 1  $\frac{1}{2}$  inches long when mature; feeds on the tender leaves.

*Treatment*.—No satisfactory treatment known.

**LITTLE NEGRO BUG** (*Corimelana pulcra*).—Glossy black bugs,  $\frac{1}{2}$  inch in length, that collect in clusters in the axils of the leaflets and cause the plants to wilt.

*Treatment*.—Kerosene emulsion or tobacco extract.

**PARSNIP PLANT-LOUSE**.—See *Parsnip*.

**Chard**.—See *Beet*.

**Cherry**. **APHIS** (*Myzus cerasi*).—Blackish plant-lice infesting the leaves and tips of new growth.

*Treatment*.—Spray as soon as the first lice appear with whale-oil soap or tobacco extract.

**CANKER WORM**.—See *Apple*.

**CHERRY FRUIT FLIES** (*Rhagoletis cingulata* and *R. fausta*).—Small maggots infesting ripening fruit. Adults are flies with banded wings and insert their eggs under the skin of the fruit.

*Treatment*.—Spray with arsenate of lead, five pounds in one hundred gallons sweetened with three gallons molasses to kill flies before egg-laying. Should be done when flies first appear,—last of June in New York.

**CHERRY SCALE** (*Aspidiotus forbesi*).—Resembles the San José scale.

*Treatment*.—Same as for *San José Scale*. See *Apple*.

**PLUM-CURCULIO**.—See *Plum*.

**ROSE-CHAFER**.—See *Grape*.

**SLUG** (*Eriocampoides limacina*).—Larva,  $\frac{1}{2}$  inch long, blackish and slimy, feeding upon the leaves; two broods.

*Treatment*.—Arsenicals, hellebore, tobacco extract.

**CHERRY TREE TORTRIX** (*Archips cerasivorana*).—Tips of branches are frequently webbed into nests by colonies of lemon-yellow caterpillars.

*Treatment*.—Wipe out nests and destroy the caterpillars.

**PEACH TREE BORER**.—See *Peach*.

**FRUIT TREE BARK BEETLE**.—See *Peach*.

**Chestnut**. **CHESTNUT WEEVILS** (*Balaninus proboscideus* and *B. rectus*).—Brownish beetles with extremely long, slender snouts with which they bore holes into the nuts for deposition of eggs. The grubs feed on the kernel, producing wormy nuts.

*Treatment*.—No satisfactory control measures known.

## CATALOGUE OF INSECTS, continued.

- TWO-LINED CHESTNUT BORER** (*Agilus bilineatus*).—Slender, flattened grubs,  $\frac{3}{4}$  inch long when mature, burrowing under the bark and girdling the trees.  
*Treatment*.—Cut and burn infested trees to prevent spread.
- EUROPEAN FRUIT LECANIUM**.—See *Plum*.
- CHRYSANTHEMUM GREEN APHIS** (*Aphis rufomaculata*).—Small, green lice attacking the terminal shoots.  
*Treatment*.—Fumigation.
- BLACK APHIS** (*Macrosiphum sanborni*).—Small, black lice attacking the terminal shoots.  
*Treatment*.—Fumigation.
- TARNISHED PLANT-BUG**.—See *Aster*.
- CHRYSANTHEMUM LEAF-MINER** (*Oscinis* sp.).—Works in the leaves.  
*Treatment*.—Hand-picking.
- CINERARIA LEAF-TYER**.—See *Celery*.
- CITRUS BARNACLE SCALE** (*Ceroplastes cirripediformis*).—A large, dark brown scale covered with a waxy secretion  $\frac{1}{2}$  inch in length. Surface of scale sculptured like a miniature barnacle.  
*Control*.—Resin wash or kerosene emulsion before the waxy covering is secreted.
- BLACK CITRUS LOUSE** (*Toxoptera aurantiae*).—Small, dull black lice, curling the leaves and killing the new growth.  
*Control*.—Contact sprays before the leaves curl.
- BLACK SCALE** (*Saissetia oleae*).—A black, oval scale  $\frac{1}{4}$  inch in diameter with an "H"-shaped mark on the back of the female. The young are light yellow to brown, unmarked. The scales secrete honey dew in which a fungus grows smutting the fruit.  
*Treatment*.—Fumigation. On citrus, use a half to three-fourths of regular dosage between September and January. On deciduous fruits and olive, water distillate, caustic soda mechanical mixtures or distillate emulsion may be used to kill scales less than one-half grown.
- CITRUS RED-SPIDER** (*Tetranychus mytilaspidis*).—Bright red, minute mite, frequently abundant on fruit and foliage.  
*Treatment*.—Dusting with sulphur or commercial lime-sulphur solution diluted 1-35 or 50 of water.
- CITRUS THRIPS** (*Euthrips citri*).—Slender, minute, orange-yellow insects, less than one-thirtieth inch in length, scarring the fruit and injuring the foliage.  
*Treatment*.—Lime-sulphur solution one part in eighty parts water (likely to cause slight injury to foliage) or "Black Leaf 40" tobacco extract, one part in 1,300 parts water. Make four applications: (1) As the last of petals are falling; (2) ten to fifteen days later; (3) three to four weeks after the second; (4) during the months of August or September (for California). In greenhouses, fumigate with hydrocyanic acid gas.
- COTTONY CUSHION SCALE** (*Icerya purchasi*).—Red or yellowish scale insects with large, white, fluted, cottony masses which cover the eggs from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch in length.  
*Control*.—Natural enemies, principally by the common Vedalia.
- FLORIDA RED SCALE** (*Chrysomphalus anidum*).—Circular flat, brown scales,  $\frac{1}{8}$  to  $\frac{1}{4}$  inch in diameter.  
*Treatment*.—Fumigation with full dosage schedule.
- FLORIDA WAX SCALE** (*Ceroplastes floridensis*).—Oval convex, white or pinkish, waxy scales with the upper surface evenly lobed, 1-12 to  $\frac{1}{2}$  inch in diameter.  
*Control*.—Resin wash or kerosene emulsion applied to the young scales before the waxy covering is formed.
- FULLER'S ROSE BEETLE**.—See *Strawberry*.
- GLOVER'S SCALE** (*Lepidosaphes gloveri*).—Closely resembles the purple scale, but is longer and narrower.  
*Control*.—Same as for Purple Scale, which see.
- GREENHOUSE THRIPS** (*Heliothrips hamorrhoidalis*).—A slender, minute, yellowish brown insect destroying the blossoms and russeting the fruit.  
*Treatment*.—Same as for Citrus Thrips, which see.
- HEMISPHERICAL SCALE** (*Saissetia hemispherica*).—A smooth, oval, convex soft scale without markings. Common in greenhouses.  
*Treatment*.—Same as for Black Scale, which see.
- MEALY-BUG** (*Pseudococcus citri*).—Small, soft-bodied scale insects,  $\frac{1}{4}$  to  $\frac{3}{8}$  inch long, covered with a white waxy secretion.  
*Control*.—A thorough application of carbolic acid emulsion; spray under heavy pressure.
- MELON APHIS**.—See *Muskmelon*.
- MEDITERRANEAN FRUIT FLY** (*Ceratitis capitata*).—Small white maggots burrowing in a great variety of soft, juicy fruits. The parent fly is about the size of the house fly, yellowish marked with black, and with faintly banded wings. Widely distributed in the tropical and subtropical regions of the world and a most serious horticultural pest wherever it occurs. Rigid quarantine regulations have prevented its introduction into the United States.  
*Treatment*.—Sweetened arsenate of lead to kill the flies before oviposition.
- ORANGE CHIONASPIS** (*Chionaspis citri*).—Elongate, blackish brown scale with a gray margin and dark yellow exuvia.  
*Treatment*.—Fumigation; kerosene emulsion, one part in five parts of water; three applications at three-week intervals.
- ORANGE MAGGOT** (*Trypeta ludens*).—Dirty white maggots, about  $\frac{1}{2}$  inch in length when mature, burrowing in the pulp. From four to twenty maggots may occur in a single orange. The adult two-winged fly is straw-yellow in color with brownish markings and bands on the wings. A serious pest to oranges in Mexico.  
*Control*.—Pick up and destroy all infested fruit.

## CATALOGUE OF INSECTS, continued.

- ORANGE TORTRIX** (*Tortrix citrana*).—Greenish white to dark, irregularly striped caterpillars,  $\frac{1}{2}$  inch long when mature, that burrow into the rind and induce decay.  
*Control*.—Destroy all infested fruit.
- PURPLE SCALE** (*Lepidosaphes beckii*).—Reddish brown to rich purple oyster-shell-shaped scales  $\frac{1}{8}$  to  $\frac{1}{4}$  inch in length.  
*Control*.—Fumigate with full dosage schedule.
- RED SCALE** (*Chrysomphalus aurantii*).—Circular, flat, reddish scales,  $\frac{1}{8}$  to  $\frac{1}{4}$  inch in diameter.  
*Control*.—Fumigation with full dosage schedule. On deciduous trees lime-sulphur solution, one part in nine parts of water; or distillate emulsion.
- SILVER MITE** (*Eriophyes oleivorus*).—A minute, elongate four-legged yellow mite causing russeting of the orange and silvering of the lemon.  
*Control*.—Same as for Citrus Red Spider, which see.
- SOFT BROWN SCALE** (*Coccus hesperidum*).—Oval, yellowish brown, flat, soft scale, sometimes with darker markings,  $\frac{1}{4}$  inch in length.  
*Control*.—Same as for Black Scale, which see.
- WHITE-FLY** (*Aleyrodes citri* and *A. nubilifera*).—The immature stages are found on the under side of the leaves and are scale-like in form. The adults are minute white-winged flies.  
*Treatment*.—Fumigation. Fungous parasites.
- YELLOW SCALE** (*Chrysomphalus citrinus*).—Similar to the red scale but yellowish in color.  
*Control*.—Same as for Red Scale, which see.
- CLEMATIS RED SPIDER**.—See *Peach*.
- SOFT BROWN SCALE**.—See *Citrus*.
- COCONUT COCONUT SCALE** (*Aspidiotus destructor*).—Whitish to creamy transparent scales often abundant on under side of leaves and fruit.  
*Treatment*.—When occurring on young trees spray with whale-oil soap; on older trees it is advisable to remove and burn badly infested leaves.
- COCONUT BEETLE** (*Strategus anachoreta*).—Large black beetles attacking young trees near the "collar." One beetle will destroy a tree if not removed in time.  
*Treatment*.—Dig out and destroy.
- COCONUT WHITE-FLY** (*Aleyrodes cocois*).—Similar to the citrus white fly.  
*Control*.—Contact insecticides. Destroy wild food plants.
- FLORIDA RED SCALE**.—See *Citrus*.
- PALM WEEVIL** (*Rhynchophorus palmarum*).—Shining black snout beetles, the larvae of which live in young palm trees reducing the interior tissues to a mass of pulp.  
*Treatment*.—Dress all wounds with tar or similar preparations. Avoid all unnecessary pruning. Destroy all felled trees and stumps not used as traps. The beetles may be attracted by the use of injured palm cabbages and trapped under rubbish.
- RHINOCEROS BEETLE** (*Oryctes rhinoceros*).—A large beetle about 1  $\frac{1}{2}$  inches long, attacking and burrowing through the crown and stem.  
*Treatment*.—Destroy all breeding-places, such as old coconut trees, stump, and cocoa pods.
- COCOS**.—See *Coconut*.
- CODIÆUM GREENHOUSE THRIPS**.—See *Citrus*.
- MEALY-BUGS**.—See *Citrus*.
- PURPLE SCALE**.—See *Citrus*.
- COFFEE BLACK CITRUS LOUSE**.—See *Citrus*.
- COFFEE LEAF-MINER** (*Cemistoma coffeella*).—A small caterpillar about  $\frac{1}{2}$  inch long, mines in the leaves producing small brownish areas. Badly infested leaves drop.  
*Treatment*.—No satisfactory treatment known.
- HEMISPHERICAL SCALE**.—See *Citrus*.
- MEALY-BUG**.—See *Citrus*.
- COLEUS MEALY-BUG**.—See *Citrus*.
- Orthesia insignis**.—Ocherous to dark green scale insect covered with a white waxy secretion extending posteriorly into a broad plate.  
*Treatment*.—Contact insecticides.
- WHITE-FLY**.—See *Tomato*.
- CORN ARMY-WORM** (*Leucania unipuncta*).—A cut-worm-like caterpillar, which normally feeds on grass. When this food-supply is exhausted, they migrate in numbers to other fields and attack corn, wheat, and similar crops.  
*Preventive*.—To stop the advance of the "army," plow deep furrows so the dirt is thrown toward the colony; in the bottom of the furrows dig post-holes into which the caterpillars will fall and where they may be killed with kerosene.
- CHINCH-BUG** (*Blissus leucopterus*).—A red or white and black sucking bug, three-twentieths of an inch long. Attacks wheat and corn in great numbers.  
*Preventives*.—Clean farming to destroy suitable hibernating shelter. Stop the migration of the bugs from the wheat-fields into corn by maintaining along the field a dust strip 10 feet wide in which a furrow and post-hole barrier has been constructed. This may be supplemented by a coal-tar barrier.
- ANGOUMOIS GRAIN MOTH** (*Sitotroga cerealella*).—A small caterpillar living in the grains. The adult is a small grayish brown moth. Most destructive in storage.  
*Treatment*.—Fumigate with carbon bisulphid, five pounds to 1,000 cubic feet. Make bins perfectly tight and sprinkle over grain, covering with gas-proof tarpaulin. Fumigate at least twenty-four hours. This should be done when the temperature is not below 65° F. In steam-heated mills, the most practicable method of destroying grain-infesting insects is by holding temperature from 118° to 122° for several hours.

## CATALOGUE OF INSECTS, continued.

**CORN EAR-WORM** (*Heliothis armiger*).—A green or brownish striped caterpillar feeding on the corn beneath the husk. Three to six generations yearly.

*Preventives*.—Plant as early as possible, and still avoid a "set-back" to the crop.

**CORN-ROOT APHIS** (*Aphis maidiradicis*).—A bluish green aphid infesting the roots.

*Preventives*.—A short rotation period in corn, especially in dry years. Deep and thorough and repeated stirring of old corn ground in fall and spring as a preparation for corn-planting. Maintenance and increase of the fertility of the soil.

**CUTWORMS** (*Agrotis*, *Hadena*, etc.).—Soft-bodied caterpillars eating and cutting off the young plants.

*Preventives*.—Early fall plowing of grass lands intended for corn; pasturing by pigs of grass or clover land intended for corn; distributing a line of poisoned bran by means of a seed-drill. To prevent the caterpillars entering from a neighboring grass field, destroy them with a line of poisoned vegetable bait.

**GRASSHOPPERS** (*Acrididae*).—Poison them with the following mixture: Bran, twenty pounds; paris green, one pound; syrup, two quarts; oranges or lemons, three fruits; water, three and one-half gallons. Mix the bran and paris green thoroughly in a wash-tub while dry. Squeeze the juice of oranges or lemons into the water and add pulp and peel cut into small pieces. Dissolve the syrup in the water and moisten the bran mixture with it, mixing thoroughly. Sow broadcast in infested areas early in the morning.

**NORTHERN CORN ROOT-WORM** (*Diabrotica longicornis*).—A whitish grub  $\frac{1}{2}$  inch long, which burrows in the roots.

*Preventive*.—Crop-rotation; corn should not follow corn.

**SOD WEB-WORMS** (*Crambus* sp.).—Gray or brownish caterpillars about  $\frac{1}{2}$  inch long, living in silk-lined burrows in the soil at base of plant. They thrive in grass land.

*Preventive*.—Early fall plowing of grass land intended for corn, or else plow as late as possible the next spring.

**WHITE GRUBS** (*Lechnosterna* sp.).—The large white curved larvæ of the common June beetle.

*Preventives*.—Rotation of crops; do not let corn follow sod, but let a crop of clover or clover and oats intervene. To help clear sod land of grubs, pasture to hogs any time between April and October. To prevent laying of eggs in corn-field, keep the ground free from weeds during May and June. Thorough cultivation and heavy fertilization.

**WIRE-WORMS** (*Elatride*).—Hard, yellowish, or reddish, cylindrical larvæ feeding on the roots.

*Preventives*.—Crop-rotation; let clover intervene between sod and corn, planting the corn late the second or third year. Early fall plowing.

**Cornus**. **OYSTER-SHELL SCALE**.—See *Apple*.

**SAN JOSE SCALE**.—See *Apple*.

**Corylus**. **HAZELNUT WEEVIL** (*Balaninus obtusus*).—Small whitish grubs living in the kernels. The adult is a yellowish brown beetle with a long, slender snout.

*Control*.—No efficient treatment known.

**Cosmos**. **ROOT APHIS** (*Aphis middletont*).—Small bluish lice on the roots.

*Treatment*.—Tobacco dust mixed in the soil.

**Cotoneaster**. **PEAR LEAF-BLISTER MITE**.—See *Pear*.

**Cranberry**. **CRANBERRY FULGORID** (*Phylloscelis atra*).—Small, broad-bodied, black jumping insect punctures the vines, causing the leaves to turn brown and the fruit to shrivel.

*Treatment*.—"Black Leaf 40" tobacco extract, one pint to one hundred gallons of water, adding four to five pounds soap to kill young nymphs.

**CRANBERRY-GIRDLER** (*Crambus hortuellus*).—Small caterpillars, feeding on the stems just beneath the surface of the sand.

*Preventive*.—Reflow just after picking, for a week or ten days, or reflow for a day or two about June 10.

**FALSE ARMY-WORM** (*Calocampa nupera*).—Green to blackish caterpillars devouring the leaves and buds.

*Treatment*.—Reflow for from twenty-four to thirty-six hours soon after the middle of May. It may be necessary to reflow a second time. Destroy all caterpillars washed ashore while the water is on. In dry bogs, spray early in May with arsenate of lead.

**FIRE-WORM**, **CRANBERRY WORM**, or **BLACK-HEADED CRANBERRY WORM** (*Eudemis vacciniana*).—Small larva, green, black-headed, feeding upon the shoots and young leaves, drawing them together by silken threads; two broods.

*Treatment*.—Flooding for two or three days when the worms come down to pupate. Arsenicals.

**FRUIT-WORM** (*Mineola vaccinii*).—Small caterpillar working in the fruits, eating out the insides.

*Preventives*.—For bogs with abundant water, reflow for ten days immediately after picking. Let the foliage ripen, and then turn on water for winter. Draw off water early in April, and every third or fourth year hold it on until the middle of May. For dry bogs spray three times with arsenate of lead during July. Bury all screenings.

**YELLOW-HEADED CRANBERRY-WORM** (*Acleris minuta*).—Stout, yellowish green, small caterpillar, with a yellow head, webbing up the leaves as it works.

*Treatment*.—Hold the water late on the bog in spring to prevent egg-laying. Arsenicals from the middle of May till July 1.

## CATALOGUE OF INSECTS, continued.

**Cratægus**. **PLANT-LICE**.—See *Apple*.

**OYSTER-SHELL SCALE**.—See *Apple*.

**RED-HUMPED CATERPILLAR**.—See *Apple*.

**SAN JOSE SCALE**.—See *Apple*.

**SCURFY SCALE**.—See *Apple*.

**WOOLLY APHIS**.—See *Apple*.

**Cucumber**. **FLEA-BEETLES**.—See *Potato*.

**MELON-WORM**.—See *Muskmelon*.

**PICKLE-WORM** (*Diaphania nitidalis*).—Larva, about an inch long, yellowish white, tinged with green, boring into cucumbers; two broods.

*Preventives*.—Clean farming, fall plowing, and rotation of crops.

*Remedies*.—Kill the caterpillars before they enter the fruit by spraying with arsenate of lead about the time the buds begin to form, and repeat in two weeks.

**RED-SPIDER**.—See *Peach*.

**SPOTTED CUCUMBER BEETLE** (*Diabrotica 12-punctata*).—Beetle, yellowish and black spotted, about  $\frac{1}{4}$  inch long, feeding upon the leaves and fruit. Sometimes attacks fruit trees, and the larva may injure roots of corn.

*Treatment*.—Same as for *Striped Cucumber Beetle*, which see.

**STEM-BORER**.—See *Squash*.

**STRIPED CUCUMBER BEETLE** (*Diabrotica vittata*).—Beetle,  $\frac{1}{4}$  inch long, yellow with black stripes, feeding on leaves. Larva  $\frac{1}{2}$  inch long and size of a pin, feeding on roots; two broods.

*Preventive*.—Cheap boxes covered with thin muslin or screens of mosquito netting, placed over young plants.

*Remedies*.—Arsenicals in flour; arsenate of lead; ashes, lime, plaster, or fine road dust sprinkled on the plants every two or three days when they are wet; air-slaked lime; plaster and kerosene; tobacco powder, applied liberally. Apply remedies when dew is on, and see that it strikes the under side of the leaves.

**WHITE-FLY**.—See *Tomato*.

**Cucurbita**.—See *Squash*.

**Currant**. **BORER** (*Sesia tipuliformis*).—A whitish larva, boring in the canes of currants, and sometimes of gooseberries. The larva remains in the cane over winter.

*Treatment*.—In fall and early spring cut and burn all affected canes. These canes may be distinguished by a lack of vigor and by limberness.

**CURRANT APHIS** (*Myzus ribis*).—Small yellowish green lice attacking the under side of the leaves, distorting the leaves and causing them to turn red.

*Treatment*.—Contact insecticides when leaves first appear.

**CURRANT MEASURING- or SPAN-WORM** (*Cymatophora ribearia*).—Larva somewhat over an inch long, with stripes and dotted with yellow or black, feeding upon the leaves.

*Treatment*.—Hellebore, applied stronger than for currant-worm. Arsenicals; hand-picking.

**CURRANT-WORM**, or **CURRANT or GOOSEBERRY SAW-FLY** (*Pteronix ribesii*).—Larva, about  $\frac{3}{4}$  inch long, yellowish green, feeding on leaves of red and white varieties; two to four broods.

*Treatment*.—Hellebore, applied early; arsenicals for the early brood. Treatment should begin while the larvæ are on the lowermost leaves of the bushes. Before the leaves are fully grown, the holes made by the worms may be seen. The second brood is best destroyed by killing the first brood.

**FOUR-STRIPED PLANT-BUG** (*Pæcilocapsus lineatus*).—A bright yellow, black-striped bug about  $\frac{1}{2}$  inch long, puncturing the young leaves and shoots of many plants.

*Treatment*.—Jarring into a dish of kerosene. Kerosene emulsion when the nymphs are young. Cut off the tips of the shoots in early spring to destroy the eggs.

**OYSTER-SHELL SCALE**.—See *Apple*.

**SAN JOSE SCALE**.—See *Apple*.

**Cycas**. **HEMISPHERICAL SCALE**.—See *Citrus*.

**MEALY-BUG**.—See *Citrus*.

**OLEANDER SCALE**.—See *Hedera*.

**RED SCALE**.—See *Citrus*.

**SOFT BROWN SCALE**.—See *Citrus*.

**WHITE PEACH SCALE**.—See *Peach*.

**Dahlia**. **GREENHOUSE THRIPS**.—See *Citrus*.

**TARNISHED PLANT-BUG**.—See *Aster*.

**Date**. **DATE PALM SCALE** (*Parlatoria blanchardii*).—Small elongate gray or black scales with white edges. Male scales are white.

*Treatment*.—Crop close, burn over trunks, after saturating with gasoline and use blast torch.

**MARLATT SCALE** (*Phanicooccus marlatti*).—A soft-bodied, oval, wine-red insect, one twenty-fifth inch in length, partially covered with white wax, found in large colonies at base of leaves.

*Treatment*.—Carbolic acid emulsion poured in large quantities at base of leaves.

**OLEANDER SCALE**.—See *Hedera*.

**RED SCALE**.—See *Citrus*.

**RHINOCEROS BEETLE**.—See *Coconut*.

**Dewberry**.—See *Bramble Fruits*.

**Diospyros**. **WHITE FLY**.—See *Citrus*.

**WHITE PEACH SCALE**.—See *Peach*.

**Dracæna**. **LONG-TAILED MEALY-BUG** (*Pseudococcus longispinus*).—Similar to the common mealy-bug, but has two long white anal appendages.

*Treatment*.—Same as for mealy-bug.

## CATALOGUE OF INSECTS, continued.

- Echinocactus.**—See *Cactus*.  
**Echinocereus.**—See *Cactus*.  
**Echinopsis.**—See *Cactus*.  
**Eggplant.**—See article on *Eggplant*.  
**Elm.**—See *Ulmus*.  
**Eucalyptus.** BLACK SCALE.—See *Citrus*.  
 OLEANDER SCALE.—See *Hedera*.  
 RED SCALE.—See *Citrus*.  
**Eupatorium.** BARNACLE SCALE.—See *Citrus*.  
**Evonymus.** EVONYMOUS SCALE (*Chionaspis evonymi*).—Dark brown, convex scales, about one-twelfth inch in diameter with yellow exuviae. Male scales pure white parallel sides and strongly tricarinated.  
*Treatment.*—Spray with kerosene emulsion every two weeks during the hatching periods until the scale has disappeared.  
 RED SCALE.—See *Citrus*.  
**Ferns.** FLORIDA WAX SCALE.—See *Citrus*.  
 GREENHOUSE THIRPS.—See *Citrus*.  
 HEMISPHERICAL SCALE.—See *Citrus*.  
 MEALY-BUGS.—See *Citrus*.  
 OLEANDER SCALE.—See *Hedera*.  
 SOUTHERN FERN-CUTWORM (*Callopietria floridensis*).—Velvety black or apple-green caterpillars, 1½ inches in length when mature, feeding on the fronds.  
*Treatment.*—Try poisoned baits.  
**Ficus.** COTTONY CUSHION SCALE; GREENHOUSE THIRPS; MEALY-BUG; PURPLE SCALE; RED SCALE; SOFT BROWN SCALE.—See *Citrus*.  
**Fuchsia.** GREENHOUSE THIRPS.—See *Citrus*.  
 MEALY-BUGS.—See *Citrus*.  
 RED-SPIDER.—See *Peach*.  
 WHITE FLY.—See *Tomato*.  
**Gardenia.** CITRUS WHITE FLY.—See *Citrus*.  
 JAPANESE WAX SCALE (*Ceroplastes ceriferus*).—White to creamy waxy masses, ¼ to ¾ inch in diameter.  
*Control.*—Young scales may be killed with kerosene emulsion before the waxy covering is formed.  
 ORTHEZIA.—See *Coleus*.  
**Genista.** GENISTA CATERPILLAR (*Mecyna reversalis*).—Pale yellowish brown caterpillars marked with numerous black spots and setae, feeding on the foliage.  
*Treatment.*—Arsenicals.  
**Geranium.** MEALY-BUGS.—See *Citrus*.  
 RED-SPIDER.—See *Peach*.  
 WHITE-FLY.—See *Tomato*.  
**Gooseberry.** CURRANT-BORER; CURRANT MEASURING- or SPAN-WORM; FOUR-STRIPED PLANT-BUG; GOOSEBERRY- or CURRANT-WORM.—See *Currant*.  
 GOOSEBERRY PLANT-WORM (*Dakruma convolutella*).—Larva about ¾ inch long, greenish or yellowish, feeding in the berry, causing it to ripen prematurely.  
*Treatment.*—Destroy affected berries. Clean cultivation. Poultry.  
**Grape.** GRAPE-CURCULIO (*Craonius inaequalis*).—Larva small, white, with a brownish head. Infests the grape in June and July, causing a little black hole in the skin and a discoloration of the berry immediately around it. The adult is a grayish brown snout-beetle, about one-tenth inch long.  
*Treatment.*—Spray with arsenate of lead while the beetles are feeding on the leaves. The beetles may be jarred down on sheets, as with the plum-curculio. Bag the clusters.  
 GRAPE ROOT-WORM (*Pidia viticida*).—The small white grubs feed upon the roots, often killing the vines in a few years. The adults are small grayish brown beetles that eat peculiar chain-like holes in the leaves during July and August.  
*Treatment.*—Cultivate thoroughly in June, especially close around the vines to kill the pupae in the soil. At the first appearance of the beetles, spray the plants with arsenate of lead at the rate of eight or ten pounds in one hundred gallons of water, to which should be added one gallon of molasses.  
 GRAPE-SLUG or SAW-FLY (*Selandria vitis*).—Larva, about ½ inch long, yellowish green with black points, feeding upon the leaves; two broods.  
*Remedies.*—Arsenicals; hellebore.  
 GRAPEBERRY-WORM (*Polychoris viteana*).—Larva, about ¼ inch long, feeding on the berry, often securing three or four together by a web; two broods.  
*Remedy.*—Spray with arsenate of lead before blossoms open. Repeat after blooming and again in early July. Destroy wormy berries in August.  
 GRASSHOPPERS.—See *Corn*.  
 GRAPE-VINE FLEA-BEETLE (*Graptoidea chalybea*).—Beetle, of a blue metallic color, about ¾ inch long, feeding upon the buds and tender shoots in early spring.  
*Treatment.*—Arsenicals to kill the grubs on leaves during May and June. The beetle can be caught by jarring on bright days.  
 GRAPE-VINE ROOT-BORER (*Memytus polistiformis*).—Larva 1½ inches or less long, working in the roots.  
*Preventive.*—Thorough cultivation during June and July.  
*Treatment.*—Dig out the borers.  
 GRAPE-VINE SPHINX (*Ampelophaga myron*).—A large larva, 2 inches long when mature, green with yellow spots and stripes, bearing a horn at the posterior extremity, feeding upon the leaves, and nipping off the young clusters of grapes; two broods.

## CATALOGUE OF INSECTS, continued.

- Treatment.*—Hand-picking. Arsenicals early in the season. There are other large sphinx caterpillars which feed upon the foliage of the vine and which are readily kept in check by hand-picking and spraying.  
**LEAF-HOPPER** (*Typhlocyba comes*).—These small yellowish leaf-hoppers, erroneously called "thrips," suck the sap from the under side of the leaves, causing them to turn brown and dry up.  
*Treatment.*—Spray the under side of the leaves very thoroughly with one gallon "Black Leaf 40" in 1,000 gallons of water about July 1, to kill the young leaf-hoppers. When using tobacco extract, add about two pounds soap to each fifty gallons to make it spread and stick better. Repeat the application in a week or ten days. In houses, tobacco smoke, pyrethrum poured upon coals held under the vines, syringing with tobacco-water or soapsuds.  
**PHYLLOXERA** (*Phylloxera vastatrix*).—A minute insect preying upon the roots, and in one form causing galls upon the leaves.  
*Preventive.*—As a rule, this insect is not destructive to American species of vines. Grafting upon resistant stocks is the most reliable method of dealing with the insect yet known. This precaution is taken to a large extent in European countries and in California, as the European vine is particularly subject to attack.  
*Remedies.*—There is no reliable and widely practicable remedy known.  
**ROSE-CHAFER** (*Macrodactylus subspinosus*).—The ungainly, long-legged grayish beetles occur in sandy regions, and often swarm into vineyards and destroy the blossoms and foliage.  
*Treatment.*—At the first appearance of the beetles, spray with arsenate of lead at the rate of eight or ten pounds in one hundred gallons of water, to which should be added one gallon of molasses.  
**TREE CRICKET.**—See *Bramble Fruits*.  
**Grapefruit.**—See *Citrus*.  
**Guava.** BLACK SCALE.—See *Citrus*.  
 GUAVA MEALY-BUG (*Pseudococcus nipa*).—Closely resembles the ordinary mealy-bug.  
*Treatment.*—Carbolic acid emulsion.  
 HEMISPHERICAL SCALE.—See *Citrus*.  
 MEDITERRANEAN FRUIT FLY.—See *Citrus*.  
**Hedera.** BLACK SCALE; FLORIDA RED SCALE; HEMISPHERICAL SCALE; MEALY-BUGS.—See *Citrus*.  
 OLEANDER APHIS (*Aphis nerii*).—Deep yellowish plant-lice, marked with black, cluster on the young shoots and buds.  
*Treatment.*—Contact insecticides.  
 OLEANDER SCALE (*Aspidiotus hederae*).—Flat, circular, gray scales, ½ inch in diameter.  
*Treatment.*—Same as for *San José Scale* (apple), which see.  
 SOFT BROWN SCALE.—See *Citrus*.  
**Helianthus.** STEM MAGGOT.—See *Artichoke*.  
**Heliotropium.** RED-SPIDER.—See *Peach*.  
**Hibiscus.** MELON APHIS.—See *Muskmelon*.  
**Hickory.** GALL APHIS (*Phylloxera* sp.).—Yellowish green plant-lice causing hollow galls on the leaves, petioles and small twigs.  
*Treatment.*—Spray with contact insecticides just as the buds are opening.  
 HICKORY BARK BEETLE (*Eccoptogaster quadrispinosa*).—Small brown beetle burrowing into twigs, buds and green nuts in June and July. Early in August the females penetrate the bark of living trees forming longitudinal burrows along the sides of which eggs are deposited. The grubs burrow transversely in the sap-wood, soon killing the trees.  
*Treatment.*—Cut and burn all infested trees before May of each year.  
 NUT WEEVIL.—See *Pecan*.  
 TWIG-GIRDLER.—See *Apple*.  
**Hollyhock.** HOLLYHOCK BUG (*Orthotylus delicatus*).—A small green bug attacking the hollyhock with much damage.  
*Treatment.*—Kerosene emulsion; tobacco extracts.  
 MELON APHIS.—See *Muskmelon*.  
**Horse-Radish.** CABBAGE-WORM.—See *Cabbage*.  
 FLEA BEETLES.—See *Potato*.  
 HARLEQUIN CABBAGE-BUG.—See *Cabbage*.  
**Ipomoea.** SOFT BROWN SCALE.—See *Citrus*.  
**Iris.** WHITE-FLY.—See *Citrus*.  
**Jasminum.** CITRUS WHITE-FLY.—See *Citrus*.  
 SOFT BROWN SCALE.—See *Citrus*.  
**Juglans.**—See *Hickory*.  
**Juniper.** BAGWORM (*Thyridopteryx ephemeraeformis*).—Small caterpillars in curious bag-like shelters defoliating the trees in early summer.  
*Treatment.*—Arsenate of lead, two pounds to one hundred gallons of water.  
 JUNIPER SCALE (*Diaspis carueli*).—Snow-white, circular scales with yellow central exuviae.  
*Treatment.*—Nothing known.  
 JUNIPER WEB-WORM (*Phalonia rutilana*).—Small flesh-colored caterpillar that webs the leaves together.  
*Treatment.*—Arsenicals.  
**Kale.**—See *Cabbage*.  
**Kohlrabi.**—See *Cabbage*.  
**Kumquat.**—See *Citrus*.

## CATALOGUE OF INSECTS, continued.

**Lantana.** GREENHOUSE WHITE-FLY.—See *Tomato*.

MEALY-BUGS.—See *Citrus*.

ORTHEZIA.—See *Coleus*.

**Larix.** CASE-BEARER (*Coleophora laricella*).—A small reddish brown caterpillar mining the leaves when young. In September it constructs a case and feeds on the surrounding leaves for a time, migrates to the branches and there hibernates.

*Treatment*.—Spray with lime-sulfur before the buds open to destroy the hibernating caterpillars.

**LARCH SAW-FLY** (*Lygeonematus erichsonii*).—Grayish green larvæ with black heads feeding on the foliage.

*Treatment*.—Spray with arsenicals.

**Laurus.** BLACK SCALE.—See *Citrus*.

FROSTED SCALE.—See *Apricot*.

SOFT BROWN SCALE, and THRIPS.—See *Citrus*.

WHITE PEACH SCALE.—See *Peach*.

**Lemon.**—See *Citrus*.

**Lespedeza.** SMOKY CRANE-FLY (*Tipula infusata*).—Dirty yellowish maggots,  $\frac{1}{2}$  inch long, feeding on the roots, often in great abundance.

*Treatment*.—Short crop-rotation.

**Lettuce.** APHIS, or GREEN-FLY (*Macrosiphum lactuæ*).—A plant-louse on forced lettuce.

*Preventive*.—Tobacco-dust applied on the soil and plants as soon as the aphid makes its appearance, or even before. Renew every two or three weeks if necessary. Fumigating with tobacco is the surest remedy.

**CABBAGE-LOOPER** (*Autographa brassiæ*).—Larva somewhat over an inch long, pale green, with stripes of a lighter color, feeding on leaves of many plants, as cabbage, celery, and endive.

*Remedies*.—Pyrethrum diluted with not more than three times its bulk with flour; kerosene emulsion; hot water.

GREENHOUSE WHITE-FLY.—See *Tomato*.

**ROOT-LOUSE** (*Rhizobius lactuce*).—Small dull-whitish lice, about one-tenth inch in length, feeding on the roots.

*Treatment*.—Crop-rotation and tobacco dust placed in the soil about the plants.

**Liriodendron.** TULIP TREE SCALE (*Toumeyella liriodendri*).—Large, nearly hemispherical scales clustered in masses on the under side of branches.

*Treatment*.—Scrape badly infested branches. Spray with kerosene emulsion or soap solution.

**Lupine.** LUPINE APHID (*Macrosiphum albigrons*).—Large, green lice covered with fine white powder, infesting the plants.

*Treatment*.—Contact insecticides.

**Lycopersicum.**—See *Tomato*.

**Magnolia.** BLACK SCALE; CITRUS WHITE FLY; GLOVERS' SCALE.—See *Citrus*.

MAGNOLIA SCALE (*Neolecanium cornuparvum*).—Large, convex scales, pinkish in color, and covered with fine powdered wax.

*Treatment*.—Kerosene emulsion or tobacco extract to kill the young scales.

**Maclura.** Treated under *Toxylon*.

**Mangifera.** CITRUS MEALY-BUG.—See *Citrus*.

**FRUIT FLY** (*Anastrepha acidusa*).—Small yellowish maggots infesting the ripening fruit.

*Treatment*.—Try sweetened arsenate of lead to kill the flies.

GREENHOUSE WHITE-FLY.—See *Citrus*.

**MANGO WEEVIL** (*Cryptorhynchus mangiferæ*).—Brown weevils about  $\frac{1}{4}$  inch long, the grubs living within the seeds.

*Treatment*.—Gather and destroy all fallen fruit.

**Mimulus.** *Ceropeto yuccæ*.—Closely resembles the common mealy-bug.

*Treatment*.—As for mealy-bugs.

**Monstera.** SCALE (*Hemichionaspis aspidistra*).—Brownish, oyster-shell-shaped scales, attacking the foliage.

*Treatment*.—Wash the leaves with soapsuds and tobacco extract.

**Mushroom.** MAGGOTS (*Sciara* sp.).—Small whitish or yellowish white maggots with black heads.

*Treatment*.—Exclude flies from house or cellar with fine screens. Sterilize manure by heating to 150° F. Fumigate with tobacco.

**MUSHROOM MITÉ** (*Tyroglyphus lintneri*).—A minute mite preventing growth of spawn by eating the mycelium.

*Control*.—In infested houses remove all compost and disinfect by drenching cellar with boiling water. Use sterilized manure.

**SPRINGTAILS** (*Achoreutes* sp.).—Small black or brown jumping insects which sometimes swarm in on the beds.

*Treatment*.—Fumigate with potassium cyanide, three to six ounces to each 1,000 cubic foot of air-space. Sterilize all manure with heat before using.

**SOWBUGS** (*Armadillidium* sp. and *Porcellio* sp.).—Oval, grayish or slate-colored creatures bearing seven pairs of legs; frequently injure mushrooms. These are commonly known as sowbugs and pillbugs.

*Treatment*.—Mix one quart of cornmeal with sufficient brown sugar to sweeten, then add two tablespoonfuls of paris green. Moisten with water and scatter in places frequented by these sowbugs.

**Muskmelon.** MELON APHIS (*Aphis gossypii*).—Small, dark green, sluggish lice found abundantly on melon vines, causing curling of the leaves and death of the plant.

## CATALOGUE OF INSECTS, continued.

*Treatment*.—Fumigate with tobacco preparations under cloth-covered frames placed over the plants. Cloth should be treated with linseed oil before using, to make gas-proof. In large fields, spray with "Black Leaf 40" tobacco extract, three-fourths pint to one hundred gallons of water, adding four pounds of soap.

**MELON CATERPILLAR** (*Diaphania hyalinata*).—Pale, greenish yellow caterpillar about  $\frac{1}{2}$  inch in length when mature, feeding on the foliage early in the season; later boring in the fruits.

*Treatment*.—Use arsenicals early in the season.

**PICKLE-WORM.**—See *Cucumber*.

STEM-BORER.—See *Squash*.

**Narcissus.** GREEN APHIS.—Tobacco extract, soap solution or fumigation.

**NARCISSUS BULB FLY** (*Merodon equestris*).—Grayish maggots,  $\frac{1}{2}$  to  $\frac{3}{4}$  inch in length when mature, feeding in the bulb. The adult is a large hairy fly.

*Control*.—Examine bulbs and discard infested ones, burning them. If bulbs are placed in water for from two to eight days the maggots will usually leave them.

**Nasturtium.** APHIS. A dark-colored plant-louse.

*Treatment*.—Spray the plants with tobacco extract or soap solution.

**Nectarine.**—See *Peach*.

**Nelumbo.** PLANT-LICE.—Use tobacco preparations for controlling these pests.

**Nepenthes.** MEALY-BUGS.—See *Citrus*.

**Nerium.** OLEANDER SCALE.—See *Hedera*.

**Oak.** BROWN-TAIL MOTH.—See *Apple*.

GIPSY MOTH.—See *Apple*.

**PIT-MAKING OAK-SCALE** (*Asterolecanium variolosum*).—Circular greenish yellow scales with a glassy appearance. Especially destructive to golden oak.

*Treatment*.—Kerosene emulsion or soap solution.

**TENT CATERPILLARS;** TUSsock Moth; TWIG-PRUNER.—See *Apple*.

**Okra.** MELON APHIS.—See *Muskmelon*.

**Olive.** BLACK SCALE.—See *Citrus*.

BLACK CITRUS LOUSE.—See *Citrus*.

**Chrysomphalus rossi**.—Circular or oblong, reddish to dark brown scale with a central black spot.

*Treatment*.—Same as for *Red Scale*.—See *Citrus*.

OLEANDER SCALE.—See *Hedera*.

PINEAPPLE SCALE.—See *Pineapple*.

PURPLE SCALE; RED SCALE; THRIPS.—See *Citrus*.

**Onion.** BLACK ONION FLY (*Tritoza flexa*).—Whitish maggots attacking the bulbs of onions.

*Treatment*.—Same as for cabbage maggot.

**ONION MAGGOT** (*Phorbia cepetorum*).—Small maggot feeding on the bulb and roots; several generations.

*Treatment*.—Use lime, tobacco dust or hellebore as repellents to prevent oviposition. Some of the maggots may be killed by applying carbolic acid emulsion or hellebore decoction to the soil about the plants.

CUTWORMS.—See *Corn*.

**ONION THRIPS** (*Thrips tabaci*).—Minute, elongate, pale yellow insects attack the leaves, causing them to wilt.

*Treatment*.—Tobacco sprays. Spray with paris green one pound in one hundred gallons water sweetened with twenty pounds brown sugar when thrips first appear.

**Orange.**—See *Citrus*.

**Orchids.** HEMISPHERICAL SCALE.—See *Citrus*.

**ORCHIDS ISOSOMA** (*Isosoma orchidearum*).—Small, white larvæ infesting the buds causing them to become unduly enlarged.

*Treatment*.—Cut off and destroy infested buds.

**SCALE INSECTS.**—Several species.

*Treatment*.—Wash plants with nicotine solutions and soapsuds.

**Papaver.** PLANT-LOUSE (*Aphis rumicis*).—Shining black plant-louse that clusters on leaves and stems.

*Treatment*.—Contact insecticides.

**Parsnip.** PARSLEY-WORM (*Papilio asterias*).—Larva,  $1\frac{1}{2}$  inches long, light yellow or greenish yellow with lines and spots; feeds upon leaves of parsley, celery, carrot, and related plants. When the worm is disturbed it ejects from the anterior end two yellow horns, with an offensive odor.

*Remedies*.—Hand-picking. Poultry are said to eat them sometimes. Upon parsnips, arsenicals.

**PARSNIP-LOUSE** (*Hyadaphis pastinacæ*).—Greenish plant-lice.

*Treatment*.—Contact insecticides.

**PARSNIP WEB-WORM** (*Depressaria heracliana*).—Larva, about  $\frac{1}{2}$  inch long, feeding in the flower-cluster and causing it to become contorted.

*Treatment*.—Arsenicals, applied as soon as the young worms appear, and before the cluster becomes distorted. Burn the distorted umbels. Destroy all wild carrots.

**PARSNIP LEAF-MINER** (*Acidia fratria*).—Small, whitish maggots mining the leaves.

*Treatment*.—Hand-pick infested leaves.

**Passiflora.** MEALY-BUGS.—See *Citrus*.

**Pea.** CUT-WORMS.—See *Corn*.

**PEA-WEEVIL, or PEA-BUG** (*Bruchus pisi*).—A small brown-black beetle, living in peas over winter. The beetle escapes in fall and spring, and lays its eggs in young pea-pods, and the grubs live in the growing peas.

## CATALOGUE OF INSECTS, continued.

*Treatment.*—Hold over infested seed one year before planting. Late planting in some localities. Fumigation with carbon bisulfid.

**PEA APHIS** (*Macrosiphum pisi*).—A rather large green plant-louse, often attacking peas in great numbers and causing enormous losses.

*Treatment.*—Rotation of crops, early planting. When peas are grown in rows, the brush-and-cultivator method may be used. The plant-lice are brushed from the plants with pine boughs, and a cultivator follows stirring the soil. This operation should be performed while the sun is hot and the ground dry. Most of the lice will be killed before they can crawl back to the plants. Repeat every three to seven days.

**Peach. BLACK APHIS** (*Aphis persicae-niger*).—A small black or brown plant-louse, which attacks the tops and roots of peach trees. When upon the roots it is a very serious enemy, stunting the tree and perhaps killing it. Thrives in sandy lands.

*Treatment.* Kerosene emulsion; tobacco decoction and extracts.

**CLOVER MITE** (*Bryobia pratensis*).—Small reddish mites attacking the leaves, causing them to turn yellow.

*Treatment.*—Lime-sulfur while trees are dormant. In summer, use self-boiled lime-sulfur, as a dust, or sulfur paste.

**FLAT-HEADED BORER.—See *Apple*.**

**FRUIT TREE BLACK BEETLE** (*Scolytus rugulosus*).—A small beetle similar to the peach tree bark-beetle.

*Treatment.*—Same as for *Peach Tree Bark-Beetle*, which see.

**KATYDID.—This insect is often troublesome to the peach in the southern states in the early spring, eating the leaves and girdling young stems.**

*Remedy.*—Poisoned baits placed about the tree.

**GREEN PEACH-LOUSE or APHIS** (*Myzus persicae*).—A small insect feeding upon the young leaves, causing them to curl and die.

*Treatment.*—Lime-sulfur, kerosene emulsion, or tobacco extract. After the buds open, either the last two.

**PEACH TREE BARK-BEETLE** (*Phloeotribus liminaris*).—A dark brown beetle one-tenth inch in length burrowing under the bark.

*Treatment.*—Burn all brush and worthless trees as soon as the infestation is observed. Keep the trees in healthy condition by thorough cultivation and the use of fertilizers. Apply a thick whitewash to the trunk and branches three times a season: (1) the last week of March, (2) second week in July, (3) first week in October.

**PEACH TREE-BORER** (*Sanninoidea exitiosa*).—A whitish larva, about  $\frac{3}{4}$  inch long when mature, boring into the crown and upper roots of the peach, causing gum to exude.

*Remedies.*—Dig out the borers in June and mound up the trees. At the same time apply gas-tar or coal-tar to the trunk from the roots up to a foot or more above the surface of the ground.

**PEACH TWIG-MOTH** (*Anarsia lineatella*).—The larva of a moth,  $\frac{1}{4}$  inch long, boring in the ends of the shoots, and later in the season attacking the fruit. Several broods.

*Remedy.*—Spray with lime-sulfur just after the buds swell. Spray trunks and larger branches in late spring to kill first brood pupæ in the curls of bark.

**PLUM-CURCULIO** (*Conotrachelus nenuphar*).—This insect may be successfully controlled on peach by spraying with arsenate of lead, four pounds to one hundred gallons of self-boiled lime-sulfur. Spray, first, when the "husks" drop from the fruit; second, ten days or two weeks later. It is unsafe to spray peaches more than twice with arsenate of lead.

**RED-SPIDER, or MITE** (*Tetranychus bimaculatus*).—A small mite infesting many plants, both in the greenhouse and out-of-doors. It flourishes in dry atmospheres, occurring on the under sides of the leaves. In some forms it is reddish, but usually light-colored and two-spotted. Common.

*Remedies.*—Persistent syringing with water will generally destroy them, if the spray is applied to the under surface. Use lots of force and little water to avoid drenching the beds. Sulfur and water. Dry sulfur. On orchard trees, flour paste.

**ROUND-HEADED APPLE TREE BORER.—See *Apple*.**

**WHITE PEACH SCALE** (*Diaspis pentagona*).—Circular gray scales with the exuviae, at one side of the center.

*Remedy.*—Same as for *San José Scale*. See *Apple*.

**Pear. APPLE TREE-BORER; BUD-MOTH; CODLIN-MOTH; FLAT-HEADED BORER.—See *Apple*.**

**MIDGE** (*Diplosis pyripora*).—A minute mosquito-like fly; lays eggs in flower-buds when they begin to show white. These hatch into minute grubs which distort and discolor the fruit. New York and eastward. Prefers the Lawrence. Introduced in 1877 from France.

*Remedies.*—Destroy the infested pears. Cultivate and plow in late summer and fall to destroy the pupæ then in the ground.

**PEAR-LEAF BLISTER-MITE** (*Eriophyes pyri*).—A minute mite which causes black blisters to appear upon the leaves. The mites collect under the bud-scales in winter.

*Remedy.*—Lime-sulfur or miscible oil as a dormant spray.

**PEAR PSYLLA** (*Psylla pyricola*).—These minute, yellowish, flat-bodied, sucking insects are often found working in the axils of the leaves and fruit early in the season. They develop into minute, cicada-like jumping-lice. The young psyllas secrete a large quantity of honey-dew, in which a peculiar black fungus grows, giving the bark a characteristic sooty appearance. There may be four broods annually, and the trees are often seriously injured.

## CATALOGUE OF INSECTS, continued.

*Treatment.*—Clean culture; remove rough bark from trunks and larger branches to discourage adults from hibernating; spray with "Black Leaf 40" tobacco extract, one pint in one hundred gallons of water, adding four pounds soap, on warm days in November or April to kill hibernating adults. Spray with lime-sulfur, winter strength, when the blossom clusters appear, to destroy eggs.

*Summer treatment.*—Spray with "Black Leaf 40" tobacco extract just as the last of the petals are falling to kill young. Repeat if necessary.

**PEAR THRIPS** (*Euthrips pyri*).—Minute insects one-twentieth inch in length, dark brown when adult, white with red eyes when young, that attack the opening buds and young fruits in early spring. They suck the sap from the tender growth, and the females lay eggs in the fruit-stems, causing a loss of the crop. The nymphs hibernate in the ground a few inches from the surface. A serious pest in California and recently introduced into New York.

*Treatment.*—Thorough cultivation during October, November, and December (in California). Make two applications of "Black Leaf" tobacco extract, one gallon in sixty gallons of 2 per cent distillate oil emulsion, the first just as the fruit-buds begin to open, the second just after the petals fall. In the East it may be controlled by timely applications of tobacco extract and whale-oil soap.

**PEAR-TWIG BEETLE** (*Xyleborus pyri*).—Brownish or black beetle, one-tenth inch long, boring in twigs, producing effect much like pear blight, and hence often known as "pear-blight beetle." It escapes from a minute perforation at base of bud; probably two broods.

*Treatment.*—Burn twigs before the beetle escapes.

**PECAN. BUD-MOTH** (*Proteopteryx deludana*).—A brownish caterpillar about  $\frac{1}{2}$  inch in length, feeding on the opening buds in early spring and on the under side of the leaves in summer.

*Treatment.*—Arsenate of lead in summer to kill larvæ of second brood. Lime-sulfur and arsenate of lead in dormant season just before buds open, to destroy hibernating larvæ.

**CASE-BEARER** (*Acrobasis nebulella*).—A small caterpillar living inside a case which it carries with it. It attacks the opening buds.

*Treatment.*—Arsenate of lead as soon as the buds begin to open. Repeat if necessary.

**BORER** (*Sesia scitula*).—A wood-boring caterpillar working in the sap-wood.

*Treatment.*—Digging out.

**PECAN WEEVIL** (*Calaminius caryæ*).—A dull, dark brown beetle with a long and slender snout with which it punctures the husk and shell of the maturing nuts for oviposition. The grubs live within the nut feeding on the kernel.

*Treatment.*—Destroy all infested nuts. This should be as soon as they fall.

**ROSE-CHAFER.—See *Grape*.**

**ROUND-HEADED BORER.—See *Apple*.**

**SLUG.—See *Cherry*.**

**TWIG-GIRDLER** (*Oncideres cingulatus*).—A brownish gray beetle, about  $\frac{1}{2}$  inch long, which girdles twigs in August and September. The female lays eggs above the girdle. The twigs soon fall.

*Remedy.*—Burn the twigs, either cutting them off or gathering them when they fall.

**TWIG-PRUNER.—See *Apple*.**

**Persimmon. TWIG-GIRDLE.—See *Pecan*.**

**WHITE PEACH-SCALE** (*Diaspis pentagona*).

*Remedy.*—Lime-sulfur when the trees are thoroughly dormant.

**Picea. SPRUCE BUD-WORM** (*Tortrix fumiferana*).—Small caterpillar feeding on the young foliage, causing the tips of the twigs to turn reddish, due to the dying of the foliage. Frequently serious in forests.

**SPRUCE GALL APHID** (*Chermes abietis*).—Plant-lice causing cone-shaped, many-celled galls at the bases of young shoots.

*Treatment.*—Spray with whale-oil soap, one pound in two gallons of water, in early spring. Cut off all galls and burn before the lice leave them.

**Pine. PINE LEAF-SCALE** (*Chionaspis pinifoliae*).—Small white scales frequently abundant on the foliage.

*Treatment.*—Kerosene emulsion or tobacco extracts when the young are hatching.

**PINE WEEVIL** (*Pissodes strobi*).—Small grub working in the terminal branch, which is killed, causing distorted trees.

*Treatment.*—Cut out and burn infested branches.

**Pineapple. KATYDID** (*Acanthacara similis*).—A large katydid which attacks, among other plants, the leaves of the pineapple.

*Remedy.*—Arsenicals, before the plants are mature.

**MEALY-BUGS** (several species).—These mealy white insects attack the plant at the base of the leaves, usually underground.

*Treatment.*—Set only clean plants, or dip them in resin wash or kerosene emulsion. In the field apply tobacco dust freely in the bud before the bloom begins to appear, or spray with kerosene emulsion.

**PINEAPPLE SCALE** (*Diaspis bromeliæ*).—Circular, thin, pure white scales with yellow exuviae infesting leaves and fruit.

*Treatment.*—Kerosene emulsion and resin wash.

**RED-SPIDER** (*Stigmaeus floridanus*).—Minute mites occurring in great number at the base of the leaf, where they induce rot.

*Treatment.*—Tobacco dust applied to bud.

## CATALOGUE OF INSECTS, continued.

- Plum. CANKER-WORM.**—See *Apple*.  
**CURCULIO** (*Conotrachelus nenuphar*).—Larva, a whitish grub, feeding in the fruit.  
*Remedies.*—Arsenate of lead, six pounds to one hundred gallons of water; apply as soon as the calyx falls, and repeat two or three times at intervals of about ten days. Jarring the beetles on sheets very early in the morning, beginning when trees are in flower, and continuing from four to six weeks, is probably the most certain procedure. There are various styles of sheets or receptacles for catching the insects as they fall from the tree. Clean culture.  
**FLAT-HEADED BORER.**—See *Apple*.  
**PEAR-TWIG BEETLE.**—See *Pear*.  
**PLUM-GOUGER** (*Coccotorus prunicida*).—A small larva, feeding upon the kernel of the plum. The beetle bores a round hole in the plum instead of making a crescent mark like the curculio.  
*Remedy.*—Catch the beetles in a curculio-catcher.  
**SAN JOSÉ SCALE.**—See *Apple*.  
**EUROPEAN FRUIT SCALE** (*Lecanium corni*).—A large circular scale occurring on plum; occasionally very destructive.  
*Remedy.*—Thorough spraying with kerosene emulsion, one part to five of water, in the winter. More dilute emulsion or tobacco extracts in midsummer, when the young insects are on the leaves and young shoots. Miscible oils when trees are dormant.  
**SLUG.**—See *Cherry*.  
**TENT CATERPILLARS.**—See *Apple*.  
**TWIG-PRUNER.**—See *Apple*.  
**Poinsettia. MEALY-BUGS.**—See *Citrus*.  
**Pomegranate. BLACK SCALE; CITRUS THRIPS; FLORIDA WAX SCALE.**—See *Citrus*.  
**OLEANDER SCALE.**—See *Hedera*.  
**WHITE-FLY.**—See *Citrus*.  
**Pomelo.**—See *Citrus*.  
**Populus. BLACK SCALE.**—See *Citrus*.  
**COTTONWOOD LEAF-BEETLE** (*Lina scripta*).—A striped beetle feeding on the leaves and shoots of poplars and willows.  
*Remedy.*—Arsenicals.  
**OYSTER-SHELL SCALE.**—See *Apple*.  
**POPLAR BORER** (*Cryptorhynchus lapathi*).—A whitish grub burrowing in the wood.  
*Treatment.*—In nurseries, spray thoroughly about the middle of July with arsenate of lead to kill the parent beetles.  
**Potato. COLORADO POTATO-BEETLE** (*Leptinotarsa decemlineata*).—Beetle and larva feed upon the leaves.  
*Remedies.*—Arsenicals, either dry or in spray, about a third stronger than for fruits. Hand-picking the beetle.  
**FLEA-BEETLE** (*Halticini*).—Small, dark-colored jumping beetles that riddle the leaves with holes.  
*Preventive.*—Bordeaux mixture as applied for potato blight acts as a repellent.  
**POTATO TUBER-WORM** (*Phthorimæa operculella*).—A small caterpillar burrowing in the stems and tubers both in the field and in storage.  
*Preventives.*—Clean cultivation, sheep and hogs to destroy the small potatoes left in the field after digging. Crop-rotation over a considerable area. On digging, remove the potatoes at once to an uninfested storeroom. Do not leave them on the field over night.  
**STALK-WEEVIL** (*Trichobaris trinitata*).—A grub boring in the stalk of the potato near or just below the ground. Serious in the West and in some places eastward.  
*Remedy.*—Pull all infested vines as soon as they wilt, and spread them in the sun where the insects will be killed. Burn the vines as soon as the crop is harvested. Destroy all solanaceous weeds.  
**WIRE-WORMS.**—See *Corn*.  
**Primula. WHITE-FLY.**—See *Citrus*.  
**Privet or Prim. PRIVET WEB-WORM** (*Diaphania quadrastigmatis*).—Small larva feeding in webs on the young shoots of the privet, appearing early in the season; two to four broods.  
*Remedies.*—Trim the hedge as soon as the worms appear, and burn the trimmings. Probably the arsenicals will prove useful.  
**Prune.**—See *Plum*.  
**Prunus.**—See *Plum*.  
**Pseudotsuga. SEED CHALCIS** (*Megastigmus spermatrophus*).—Small whitish grub devours the kernel of the seed, often destroying the whole crop.  
 No known remedy.  
**Pyrus.**—See *Apple*.  
**Quince. GREEN APHIS.**—See *Apple*.  
**QUINCE CURCULIO** (*Conotrachelus crataegi*).—This curculio is somewhat larger than that infesting the plum, and differs in its life-history. The grubs leave the fruits in the fall, and enter the ground, where they hibernate and transform to adults the next May, June or July, depending on the season.  
*Treatment.*—When the adults appear, jar them from the tree onto sheets or curculio-catchers and destroy them. To determine when they appear, jar a few trees daily, beginning the latter part of May. Arsenicals. Pick and burn all infested fruits a month before harvest.  
**ROUND-HEADED BORERS.**—See *Apple*.  
**SLUG.**—See *Cherry*.  
**Radish. MAGGOT** (*Pegomya brassicæ*).—Treated the same as the Cabbage Maggot, which see.

## CATALOGUE OF INSECTS, continued.

- Raspberry.**—See *Bramble Fruits*.  
**Rhododendron. BORER** (*Sesia rhododendri*).—Whitish caterpillars burrowing in the trunk and larger branches which are often killed.  
*Treatment.*—Dig out borers or cut out infested branches and burn.  
**LACE BUG** (*Leptobrysa explanata*).—Small, lace-winged bugs on the under side of the leaves, causing them to turn brown and die.  
*Treatment.*—Spray with soap solution.  
**Rhubarb. RHUBARB-CURCULIO** (*Lixus concavus*).—A grub  $\frac{3}{4}$  inch long, boring into the crown and roots. It also attacks wild docks.  
*Remedy.*—Burn all infested plants and keep down the docks. Hand-picking.  
**Rhus. AF. LE TREE-BORER.**—See *Apple*.  
**JUMPING SUMAC-BEETLE** (*Blepharida rhois*).—Larva,  $\frac{1}{2}$  inch long, dull greenish yellow, feeding on leaves; two broods.  
*Remedy.*—Arsenicals.  
**Ribes.**—See *Currant*.  
**Robinia. LEAF-MINER** (*Odontota dorsalis*).—A black and yellowish white grub about  $\frac{3}{4}$  inch in length, mining the leaves, causing blister-like spots.  
*Treatment.*—Arsenate of lead the last of July to first of August.  
**LOCUST-BORER** (*Cyrtene robinia*).—Large, brownish yellow grub burrowing in the trunk, causing large ugly scars. The beetle is black prettily marked with yellow stripes and bands.  
*Remedy.*—None known.  
**Rose. MEALY-BUG.**—Tobacco extracts; syringe the plants in the morning, and two hours later syringe again with clean water.  
**ROSE APHIS** (*Macrosiphum rosæ* and *Myzus rosarum*).—Greenish plant-lice, attacking leaves and buds.  
*Treatment.*—Tobacco extracts and soap solutions.  
**ROSE-CHAFER, ROSE-BEETLE, or "ROSE-BUG."**—See *Grape*.  
**ROSE LEAF-HOPPER** (*Typhlocyba rosæ*).—A very small hopper, white, often mistaken for thrips, living on the leaves of roses.  
*Remedies.*—Whale-oil soap; kerosene; kerosene emulsion; dry pyrethrum blown on bushes when leaves are wet; tobacco extracts.  
**ROSE MIDGE** (*Neocerata rhabdophaga*).—Small maggots, distorting leaf and flower-buds.  
*Treatment.*—No satisfactory treatment known.  
**ROSE SCALE** (*Aulacaspis rosæ*).—Small, whitish circular scales.  
*Treatment.*—Soap solutions or tobacco extracts when young are hatching.  
**WHITE-FLY.**—See *Tomato*.  
**Rubus.**—See *Bramble Fruits*.  
**Salix. COTTONWOOD LEAF-BEETLE.**—See *Populus*.  
**OYSTER-SHELL SCALE.**—See *Apple*.  
**POPLAR-BORER.**—See *Populus*.  
**WILLOW-WORM** (*Euvanesa antiopa*).—Larva nearly 2 inches long, black, feeding upon leaves of willow, elm, and poplar; two broods.  
*Remedy.*—Arsenicals.  
**Salvia. ORTHEZIA.**—See *Coleus*.  
**WHITE FLY.**—See *Tomato*.  
**Scilla. NARCISSUS BULB FLY.**—See *Narcissus*.  
**Smilax. CITRUS WHITE FLY.**—See *Citrus*.  
**Solanum.**—See *Potato*.  
**Sorbus. SAN JOSÉ SCALE; SCURFY SCALE.**—See *Apple*.  
**Spinach. FLEA-BEETLE.**—See *Potato*.  
**LEAF-MINER** (*Pegomya vicina*).—Small maggot mining the leaves.  
*Treatment.*—Clean cultivation to destroy its wild food plant (lamb's quarters). Destroy all infested leaves. By raising spinach as an early or late crop, much of the damage can be avoided.  
**SPINACH APHIS** (*Myzus persicæ*).—Same as green peach aphis.  
*Treatment.*—Spray at first appearance of lice with "Black Leaf 40" tobacco extract, three-fourths pint to one hundred gallons of water, adding four pounds of soap.  
**Squash. CUCUMBER BEETLES.**—See *Cucumber*.  
**MELON APHIS.**—See *Muskmelon*.  
**SQUASH APHIS** (*Nectarophora cucurbitæ*).—Large, light green plant-lice attacking the leaves.  
*Treatment.*—Same as for melon aphis.  
**SQUASH LADY-BIRD.**—See *Cucumber*.  
**SQUASH STINK-BUG** (*Anasa tristis*).—Large, dark brown bug hibernates as adult under rubbish. Female lays large brown eggs in patches on the leaves. The young are greenish, feed in colonies on under side of leaves, causing them to wilt and die.  
*Treatment.*—Trap adults in spring under boards laid on the ground. Destroy eggs by hands. Young can be killed with "Black Leaf 40" tobacco extract, one pint in one hundred gallons of water, adding four to five pounds of soap.  
**STEM-BORER** (*Melittia satyriniiformis*).—Soft, white, grub-like larva which bores inside the stem and causes rot to develop, killing the vine.  
*Preventives.*—Plant early squashes as traps. As soon as the early crop is gathered, burn the vines to destroy eggs and larvae of the borer. Fall harrowing of infested fields will help to expose the pupæ to the elements. Cut out borers whenever found. After the vines have grown to some length, cover some of the joints with earth, so that a new root-system will develop to sustain the plant in case the main root is injured.

## CATALOGUE OF INSECTS, continued.

- Strawberry.** CROWN-BORER (*Tyloclerum fragariae*).—White grub,  $\frac{1}{2}$  inch long, boring into the crown of the plant in midsummer. The mature insect is a curculio or weevil.  
**Preventives.**—Rotation of crops. Isolation of new beds from infested beds. Plant uninfested plants.
- FULLER'S ROSE-BEETLE** (*Aramigus fulleri*).—White grub,  $\frac{1}{2}$  inch long, feeding in the crown. The adult is a grayish brown snout-beetle with a whitish bar on each wing-cover.  
**Treatment.**—Short rotation. Plant on uninfested land.
- LEAF-ROLLER** (*Ancylis comptana*).—Larva less than  $\frac{1}{2}$  inch long, feeding on the leaves, and rolling them up in threads of silk; two broods.  
**Treatment.**—Turn under in the fall all old beds that have become worthless. Spray with arsenate of lead, four pounds in one hundred gallons of water, after the eggs are laid but before the leaves are folded—the first half of May in the latitude of New Jersey.
- ROOT-BORER** (*Anarsia* sp.).—Larva about  $\frac{1}{2}$  inch long, whitish, boring into the crown of the plant late in the season, and remaining in it over winter.  
**Remedy.**—Burn the plant.
- ROOT-BORER** (*Typophorus canellus*).—A whitish grub  $\frac{1}{2}$  inch in length feeding on the roots. The parent beetle is brownish, and appears in great numbers in May.  
**Treatment.**—Arsenicals to kill the beetles. Plant new beds at a distance from old ones.
- ROOT-LOUSE** (*Aphis forbesii*).—From July to the close of the season the lice appear in great numbers on the crowns and on the roots of the plants.  
**Remedies.**—Rotation in planting. Disinfect plants coming from infested patches by dipping the crowns and roots in kerosene emulsion, or tobacco extract. Fumigation.
- SAW-FLY** (*Empyga maculatus*).—Larva nearly  $\frac{3}{4}$  inch long, greenish, feeding upon the leaves; two broods.  
**Remedies.**—Hellebore; arsenicals for second brood.
- WEEVIL** (*Anthonomus signatus*).—Beetle  $\frac{1}{8}$  inch long, reddish black, feeding on flower-buds, particularly those of the polleniferous varieties.  
**Preventives.**—Plant principally profusely flowering varieties. Clean culture. Destroy all wild blackberry and raspberry vines in the vicinity.
- WHITE GRUBS.**—See Corn.
- Sweet Pea.** TARNISHED PLANT-BUG.—See Aster. (They puncture and kill the flower-stems.)
- Sweet Potato.** CUTWORMS.—Poisoned bait; late planting; keep the land free from weeds the previous fall.
- FLEA-BEETLE** (*Chatoceoma confinis*).—Small, dark-colored beetles, which attack the plant as soon after they are reset.  
**Treatment.**—Dip the plant in a strong solution of arsenate of lead before resetting, spray once or twice later with the same. Rotation of crops. Destroy all bindweed and wild morning-glory plants.
- ROOT-BORER** (*Cylas formicarius*).—A whitish grub  $\frac{1}{4}$  inch in length, burrowing through the tubers.  
**Preventive.**—Burn infested tubers and the vines.
- SAW-FLY** (*Schizocerus obnub* and *S. privatus*).—Small larva about  $\frac{1}{4}$  inch long, working upon the leaves. The fly is about the size of a house-fly.  
**Remedies.**—Hellebore and arsenicals.
- TORTOISE BEETLES** (*Cassidini*).—Beetles of brilliant colors and their slug-like larvæ which eat holes in the leaves of newly reset plants.  
**Treatment.**—Same as for next.
- Tamarix.** CANE-BORER (*Schistocerus hamatus*).—Whitish grub,  $\frac{1}{2}$  inch in length, burrowing in the twigs.  
**Treatment.**—Cut and burn all infested branches.
- Theobroma.** CACAO BEETLE (*Steirastoma depressum*).—Large grubs,  $1\frac{1}{2}$  inches long, burrowing under the bark.  
**Control.**—Dig out or kill with a wire.
- CACAO FRUIT FLY** (*Ceratitis punctata*).—A small maggot attacking the pods.  
**Treatment.**—Spray when flies appear with sweetened arsenate of lead, four pounds to one hundred gallons of water.
- CACAO THRIPS** (*Heliothrips rubrocineta*).—Small active insects attacking leaves and pods. In the young the abdomen is banded with red.  
**Treatment.**—Careful cultivation to produce vigorous growth.
- Thuya.** BAGWORM.—See Juniper.
- Tomato.** FLEA-BEETLES.—Dip the young plants in a strong solution of arsenate of lead. Bordeaux mixture acts as a repellent.
- FRUIT-WORM** (*Heliothis obsoleta*).—Larva 1 inch in length, pale green or dark brown, faintly striped, feeding upon the fruit. Also on corn and cotton.  
**Treatment.**—Hand-picking. Avoid planting close to corn or cotton, or after either of these crops or after peas or beans. Practise fall or winter plowing.
- TOMATO-WORM** (*Phlegthontius sexta* and *P. quinquemaculata*).—A very large green worm feeding upon the stems and leaves of the tomato and husk tomato. Seldom abundant enough to be very serious; kept in check by parasites.  
**Remedies.**—Hand-picking; rotation of crops; clean culture; turkeys.
- WHITE-FLY** (*Aleyrodes vaporariorum*).—Tomatoes grown under glass are often badly infested with white flies, the young of which are scale-like and occur on the under side of the leaves.  
**Treatment.**—Fumigation.
- Toxylon.** BAGWORM.—See Juniper.
- SAN JOSÉ SCALE.**—See Apple.

## CATALOGUE OF INSECTS, continued.

- Tropæolum.**—See *Nasturtium*.
- Tsuga.** BAGWORM.—See Juniper.
- Turnip.**—See Cabbage.
- Ulmus.** CANKER-WORM.—See Apple.
- ELM LEAF-BEETLE** (*Galerucella luteola*).—A small beetle, imported from Europe, which causes great devastation in some of the eastern states by eating the green matter from elm leaves, causing the tree to appear as if scorched.  
**Remedy.**—Arsenate of lead, six pounds to one hundred gallons, just as the eggs are hatching.
- ELM SAW-FLY LEAF-MINER** (*Kahlosysphinga ulmi*).—A greenish white larva feeding between the two layers of the leaf, causing large blotches; when abundant, the leaf dies and falls. They sometimes kill the trees in two or three years.  
**Treatment.**—While the blotches are small, spray with "Black Leaf 40," tobacco extract, one gallon in 800 gallons of water, adding four pounds of whale-oil soap to each hundred gallons.
- LEOPARD MOTH** (*Zeuzera pyrina*).—White to pinkish caterpillars boring at first in the smaller twigs and branches. Later the nearly mature caterpillars attack the larger branches and trunk, doing very serious injury. The white moths, beautifully marked with black and blue, have a wing expanse of about  $2\frac{1}{2}$  inches.  
**Treatment.**—Cut off and destroy all infested branches. The spread of the pest is very slow if the branches of the trees do not interlace.
- WILLOW-WORM.**—See Salix.
- Violet.** APHIS.—Fumigation when grown under glass.
- GALL-FLY** (*Contarinia violicola*).—The adult is a minute mosquito-like fly. The whitish or yellowish maggot feeds in folds of the opening leaves, which become deformed, turn brown, and die.  
**Treatment.**—Fumigation is practically of no value. Thorough hand-picking as soon as any sign of injury is noticed. Do not let the pest become established in the house.
- RED-SPIDER** (*Tetranychus bimaculatus*).—Minute mites which cause the leaves to turn paler and become yellowish.  
**Treatment.**—On greenhouse violets there is nothing better than a stiff spray of clear water so applied as not to drench the beds. Repeat the spraying once or twice a week.
- Vitis.**—See Grapes.
- Walnut.**—See Hickory.
- Watermelon.** MELON APHIS.—See Muskmelon.
- Yucca** (*Lonchæa chalybea*).—Small maggot destroying the buds. Very serious pest.  
**Treatment.**—Collect and burn all infested shoots.
- LONG-HORNED BEETLE** (*Logochirus obsoletus*).—A white grub  $1\frac{1}{2}$  inches in length when mature, boring in the trunk and doing great damage. The adult is a large reddish brown beetle and feeds on the foliage.  
**Treatment.**—When beetles are most abundant prune plants to the ground and burn. Spray with arsenicals to destroy beetles.
- SPHINX CATERPILLARS** (*Dilophonota ello*).—Large caterpillar feeding on the foliage. The parent moth is a large hawk-moth rather showily colored.  
**Treatment.**—Arsenate of lead, six pounds to one hundred gallons of water.
- Zea.**—See Corn.

C. R. CROSBY.  
ROBERT MATHESON.

## Spraying.

Spraying is the art of protecting cultivated plants from insect enemies and vegetable parasites by covering them with a material which shall have a toxic or physically injurious effect upon the animal or vegetable organism.

## Historical sketch.

The history of spraying is interesting. The story of its progress in America differs in details from the history of its development in Europe, but the main features in each country are very similar. In both places, insect enemies made the first draft on the ingenuity of man in devising methods by which to hold them in check. Vegetable parasites were studied afterward. It is a curious fact that, in the case of both insects and fungi, in America, some of the most injurious forms came from Europe and were the means of directing attention to wholesale methods of destroying them. Some of these enemies, comparatively harmless in their native home, like the currant-worm and codlin-moth, have done more to forward spraying methods in the United States than anything else.

The first insecticides used in America, as well as in Europe, were not of a poisonous nature. They were

substances that had an injurious effect on the body of the insect. These were of two kinds, mainly: infusions which were astringent, and caustic substances which burned the tissues. Tobacco water and alkaline washes have been used for many years. One of the

1326. Apple cluster ready for the spray. The blossoms have not yet opened.

first poisons to be used was white hellebore. The employment of arsenical poisons may be said to belong to America, and even at the present time has small place in the economy of fruit-growing in Europe. The wide-spread use of arsenical poisons is largely due to the influence of the incursion of the potato-bug. There are no reliable records which give us the exact date of the first use of paris green. It probably occurred about 1865 or 1866. However, towards 1870 paris green was used very generally throughout the western region in which the potato-bug first appeared. At this time it was applied almost exclusively in the dry form diluted with gypsum or flour. From potato to cotton, tobacco and finally to fruit trees, is the development of this poison for destroying leaf-eating insects. So far as records are available, it appears that fruit trees were first sprayed with paris green between 1873 and 1875. Among pioneer sprayers, should be mentioned the names of C. V. Riley, United States Entomologist; LeBarron, State Entomologist of Illinois; William Saunders, London, Ontario, Can.; J. S. Woodward, Lockport, N. Y.; T. G. Yeomans & Sons, Walworth, N. Y.; A. J. Cook, Agricultural College, Mich.

Following paris green came london purple, then white arsenic, and later arsenate of lead. Since that time many different forms of arsenical poisons have been compounded, offered to the public and frequently used. A few years ago paris green was used extensively, but its popularity now is decreasing, probably because it contains a large percentage of soluble arsenic, which increases the danger of foliage injury. London purple has been largely dropped by fruit-growers, owing to its variable quality. White arsenic, in combination with soda and with lime, forms a reliable insecticide and is used by some growers, especially those who make a practice of preparing the home-made solutions. Arsenate of lead is the insecticide used most widely by the growers at the present time. It possesses several advantages, the more important of which are a small percentage of soluble arsenic and better sticking qualities.

The sucking insects presented a more difficult problem of control than the biting insects, and a longer time elapsed before effective methods had been devised for treatment. One of the first efficient sprays for these insects was kerosene in the form of a soap-and-water emulsion, which was recommended by Riley and Hubbard. Among the earlier sprays for these insects was also tobacco and whale-oil soaps, both of which are used rather widely at the present time. Later the

1327. Splint broom for applying spray. An early device.

miscible oils were introduced. These proved to be very effective and are still used. The most important step in the control of the sucking insects is marked by the introduction of the lime-sulfur wash. This mixture, which was originally developed as a dip for the control of scab on sheep, was first used as an insecticide on fruit trees in 1886 by F. Dusey, of Fresno, California. The wash proved very efficient and with modifications came quickly into favor. Now lime-sulfur is the leading insecticide for the control of certain scale insects and also, in a more dilute form, the leading fungicide for the more troublesome diseases of the apple.

The treatment of fungous diseases of plants by liquid applications began with the discovery of bordeaux mixture. Early in the 1880's, diseases of grape-vines threatened the extinction of French vineyards. The situation engaged the attention of French investigators. Notable among them were A. Millardet and his co-workers of the Academy of Science, Bordeaux, France. He, with others, discovered partly by accident and partly by experiment that solutions of copper prevented the development of downy mildew. After much experimentation, "bouillie Bordelaise" was found to be effective in preventing the growth of downy mildew and other plant parasites infesting the grape in that region. The announcement was definitely made in 1885. The following year the European formula for bordeaux mixture was published in several places in the United States, and immediately there began an unparalleled period of activity in economic vegetable pathology. This mixture, though somewhat modified and developed, continues to be a leading fungicide. The value of lime-sulfur as a fungicide applied to the peach during the dormant season to control the leaf-curl has been recognized. About 1907,

1328. A bucket pump.

1329. Knapsack pump.

Cordley discovered that lime-sulfur in more dilute form may be applied to the apple and some other tree fruits in foliage without danger of foliage injury, and that in addition to being as effective as bordeaux it produces no spray injury on the fruit. Since then lime-sulfur as a fungicide has practically replaced bordeaux in the case of those fruits for which it can be used on the foliage with safety. The self-boiled lime-sulfur was developed about 1907 as a fungicide for the control of the brown rot of the peach.

The rapidity of the spread of spraying knowledge among fruit-growers is remarkable. Only a few years ago it was an unknown art by the rank and file. Today agricultural clubs and granges purchase their spraying materials by the carload direct from the manufacturer. The American farmer leads his fellow-workers in all parts of the world in the practice of spraying.

1330. A garden barrel pump.

trees are not blossoming." "Certainly," we answer, "spray to protect the foliage from possible injury by insect or fungous disease." Healthy foliage is essential to the protection of health and vigor and fruit-buds. Spray this year for next year's crop.

Insecticides kill by contact or by means of a poisonous principle; their efficiency depends largely on the time and thoroughness of the application. If applied too soon they may be dissipated before the insects appear; if applied late the injury is only partly prevented, because insects feed less voraciously and are harder to kill as they approach maturity in the larval stage. With the vegetable parasite, the case is not essentially different. The tree is covered with a thin coating which destroys spores of fungi resting there and prevents other spores from germinating. Fig. 1326 shows the stage of development of fruit-bud calling for bordeaux mixture and paris green. The keynote to success is thoroughness. Hasty sprinklings are worse than useless; they discourage and disappoint the beginner. Full protection is not afforded unless each leaf, twig and branch has been covered. Time is the next most important factor bearing on success. The early spray is most effective. This applies particularly to the treatment of fungous diseases. Spray before the buds open. Get ahead of the enemy.

#### *Spraying machinery.*

Bordeaux mixture was first applied with a broom (Fig. 1327). Poison distributors were first made in America for the protection of cotton, potato and tobacco. There are five general types of pumps: (1) The

1331. An orchard barrel pump.

#### *The principles of spraying.*

A spray may be effective (1) by hitting the enemy, (2) by placing poison before the depre-dator, and (3) by protecting the plant with a covering unfavorable to the growth of the pest. The cautious farmer insures his crop against injury by insect or vegetable parasites by spraying. The fruit-grower asks, "Do I need to spray this year? My

Excellent for spraying small vineyards and vegetable-gardens. (3) A barrel pump; a strong force-pump fitted to a kerosene barrel or larger tank suitable for spraying young trees; may be mounted on a cart, wagon, or stone-boat, depending on the character of the ground and size of trees. (4) A gear-sprayer; being a tank provided with a pump and mounted on wheels. The pump is operated by power borrowed from the wheels as they revolve, and transferred by means of chain and sprockets. Suitable for vineyards and field crops, which may be satisfactorily covered by the spray as the machine moves along. For this reason it is not adapted to orchard work. (5) The power sprayer; power being furnished generally by gasoline, sometimes by compressed air. When the trees are large and the orchard over 5 acres in extent, a power sprayer will usually pay. Some of these various types of machinery are shown in Figs. 1328-1335. In recent years the spraying of field crops and shade trees has developed rapidly. The spray pumps have been adapted to this work by the use of special attachments. For the field crops, nozzles are distributed along a horizontal arm, which makes it possible to cover a wide strip. The sprayers for shade trees are equipped with a more powerful pump, which is usually multiple-cylinder. The pump must be capable of delivering a large quantity of material each minute under a pressure of 200 to 300 pounds. The nozzles for this work are of the solid stream type and are usually fitted with interchangeable tips varying from  $\frac{1}{8}$ - to  $\frac{1}{4}$ -inch aperture. In order that the tops of high trees may be reached by the spray mixture, it is necessary to use a long extension rod, as well as very high pressure.

1332. Square tower, giving more working space for the nozzle-men than the conical form.

1333. A power sprayer for orchard use.

hand portable pump, often attached to a pail or other small reservoir, suitable for limited garden areas. (2) The knapsack pump carried on a man's back and operated by the carrier. The tank is made of copper, holds five gallons and is fitted with a neat pump which may be operated with one hand while the nozzle is directed with the other. This pump has been modified recently so that all the pumping is done when the sprayer is filled and before it is placed on the shoulders.

1334. A traction power sprayer, for street and park trees.

The essentials of a good pump are (1) durability: secured by having working parts made of material least susceptible to the action of the various spray solutions, friction considered; (2) strength: obtained by a good-sized cylinder, substantial valves, wall and piston; (3) easily operated: found in a pump with a long handle, large air-chamber and smoothly finished working parts. A pump should be strong enough to feed two leads of hose and throw a good spray from four nozzles. Nearly all spray mixtures require constant stirrings to prevent settling and insure uniformity, and an agitator is a necessary part of the equipment.

**Nozzles.**—Much of the efficiency of a spraying machine depends upon the nozzle. It should be chosen for the particular work to be done, rather than for any special design. The development of nozzle construction has been rapid, new features being embodied as necessity demanded, until today there are four main types, each of which is intended for specific work: (1) The Bordeaux nozzle is the oldest of the modern types. It came into general use about 1890 and was at first universally adopted for all spray work. It throws a stream which may be regulated from a solid jet to a coarse fan-shaped spray, both of which are too coarse for general use. The Bordeaux has, however, one place in the list of modern spray nozzles and that is for the codlin-moth spray. For this application it is desirable to force the material into the calyx cups of the developing fruit and no nozzle does this quite so efficiently as the Bordeaux. (2) The Vermorel was the next step in development after the Bordeaux. It was very much superior to the latter, breaking the material up into finer particles, and was generally used until about 1906. This nozzle, however, does not possess any desirable features not found in the disc types and therefore has no special uses in modern spraying. (3) The disc nozzles are standard for general spraying work. They are represented by a large number of sorts, each made by different manufacturers, but all working on the same principle. The material is whirled inside of the nozzle before it reaches the final outlet, thus breaking it up into finely divided parts and producing the desired mist. The material is lastly passed through a disc, which may have either a large or small opening. For orchard and small crop spraying, the small opening is used, in which case the nozzle should be 3 to 7 feet from the object to be sprayed. For taller orchard trees and for small ornamental trees, the large opening is used. This produces a solid jet which breaks into finer particles at a distance from the

nozzles, depending upon the pressure used. (4) Shade tree nozzles, to be used only for spraying very tall ornamental trees, and in connection with at least 300 pounds pressure. They throw a solid stream 30 or more feet in the air, at which point the material is broken into a coarse mist. This type came into use at the time of the introduction of the brown-tail and gypsy moths in the New England states, and has since been widely used for parks, estates and forest spraying.

C. S. WILSON.

DISÉMMA: *Passiflora*.

**DISOCÁCTUS** (*two-shaped Cactus*). *Cactaceæ*. Bushy cactus, 2-3 ft. high, sometimes seen as a pot-plant in collections.

Stems terete, usually erect: branches flattened as in *Epiphyllum*: fls. regular, with very short tube; petals few, elongated, spreading; ovary nearly naked, small.

*bifórmis*, Lindl. (*Phyllocactus bifórmis*, Lab.).

Soon pendulous, the branches cylindrical: short branches lf.-like, the lower egg-shaped, the upper more lengthened: fls. small, purple-red, less than 2 in. expansion; ovary without angles and with minute scales. Honduras. B.M. 6156. V. 2:159.

J. N. ROSE.

**DÍSPORUM** (Greek, *double one-seeded*). Syn. *Prosartes*. *Liliaceæ*. FAIRY BELLS. Small perennial rhizomatous herbs, sometimes planted in the wild garden.

Allied to *Smilacina* and *Streptopus*, being leafy-stemmed, but fls. in umbels (or solitary): perianth 6-parted, with narrow deciduous segms.; stamens 6, the filaments filiform or slightly flattened and longer than the extrorse anthers; ovary 3-celled, the ovules 2 or more in each cell, the stigma 3-cleft or entire: fr. a red or reddish few-seeded berry.—About 20 species, in N. Amer. and in the Himalayan region, Java to China and Japan. Little known to horticulturists; probably require no particular skill in cult.

A. Lvs. rarely cordate at base.

B. Style 3-cleft.

**Ménziesii**, Nichols. (*Prosartes Ménziesii*, Don). More or less soft-pubescent: st. 2-3 ft. long, forking, arching above: lvs. ovate to ovate-lanceolate, narrowly acuminate or the lowest acute, sessile, 2-3 in. long, often resin-dotted: fls. 1-3, greenish, cup-shaped, from the topmost axils, nodding, 9-12 lines long; pedicels puberulous; perianth-segms. nearly erect, acute, 6-11 lines long; stamens a third shorter; anthers included, 1½-2 times shorter than the filaments: fr. oblong-

1335. Spraying park trees with the machine shown in Fig. 1334.

obovate, narrowed to a short beak, salmon-colored. Calif. to Brit. Col.

**lanuginosum**, Nichols. Woolly-pubescent: lvs. oblong-lanceolate, narrowly acuminate: perianth-segms. greenish, linear-lanceolate, acuminate, spreading, 6-9 lines long, stamens a third shorter; style and narrow ovary glabrous: caps. oblong-ovate, obtusish or with a very short, stout beak, glabrous; cells 1-2-seeded. Ont. to Ga. and Tenn. B.M. 1490. (as *Streptopus*).

BB. *Style entire.*

**trachycarpum**, Benth. & Hook. (*Prosartes trachycarpa*, Wats.). More or less pubescent: st. 1-2 ft. high, forking, with foliage on the upper half: lvs. ovate to oblong-lanceolate, acute or rarely acuminate, 2-4 in. long: pedicels pilose; perianth-segms. whitish, slightly spreading, more narrowly oblanceolate than in *D. Menziesii*, acute, 6-7 lines long, about as long as the stamens: fr. obtuse, rather deeply lobed, papillose. Neb. to Manitoba and Ore. and Wash.

AA. *Lvs. mostly cordate-clasping.*

**oregànum**, Benth. & Hook. (*Prosartes oregana*, Wats.). More or less woolly-pubescent: lvs. ovate to oblong-lanceolate, long-acuminate: perianth-segms. spreading, acute, narrowed below, very distinctly net-veined, 5-7 lines long, as long as or shorter than the stamens: fr. ovate, acutish, somewhat pubescent. Ore. and Idaho to Brit. Col.

*D. Hookeri*, Nichols. (*P. lanuginosa* var. *Hookeri*, Baker). More or less rough-pubescent, with short, usually spreading hairs: lvs. ovate or sometimes oblong: perianth rather broad at the base: fr. obovate, obtuse, red. Calif.—*D. Leschenaultianum*, D. Don, differs from the others here described by having white fls. India, Ceylon. B.M. 6935.—*D. pullum*, Salisb. Readily told from American forms by its brown or purplish green fls. India, Java, China. B.M. 916.

WILHELM MILLER.  
L. H. B.†

**DISSOTIS** (of two kinds, referring to the unlike anthers). *Melastomaceæ*. Some 60 or more species of bristly-hairy or villous shrubs, sub-shrubs or herbs of Trop. and S. Afr., some of which may occur sparingly in choice collections of coolhouse and warmhouse plants: lvs. opposite, short-stalked, linear, ovate or orbicular, usually entire, 3-5-nerved, more or less strigose above: fls. bracted, about 1 in. or more across, purple or violet, solitary, or capitate or paniculate at the ends of the branches; calyx 4-5-lobed; petals 4 or 5, obovate; stamens 8 or 10, very unequal, the anthers linear-subulate, usually beaked, with 1 pore, the larger set being joined to the filament by a long connective and the other set with much shorter or nearly obsolete connective: fr. an included coriaceous caps. 4- or 5-valved at the apex. Apparently none is in the American trade. *D. Irvingiana*, Hook. f. Annual from upper Guinea, 1-3 ft.: lvs. linear-oblong to lance-oblong, acute, 3-nerved: fls. reddish purple, to 1¼ in. across; petals obovate. B.M. 5149. *D. incana*, Triana, of Trop. and S. Afr., shrub, 2-3 ft.: lvs. linear to linear-oblong, obtuse: fls. rose-purple, to 1½ in. across. B.M. 3790. *D. plumosa*, Hook. f. Shrubby, with long and slender shoots which are densely covered with small deep green lvs.: fls. bright magenta-rose, 1½ in. across. Trop. Afr. *D. Mahonii*, Hook. f. Prostrate, the sts. 6-8 in. long: lvs. short-stalked, nearly or quite orbicular: fls. rose-purple, 2 in. across, solitary. Uganda. B.M. 7896. *D. modesta*, Stapf. Slender: lvs. oblong, minutely serrulate: fls. few, crowded at ends of branches; petals obovate-elliptic; stamens blue-purple, reddish and yellow; style purple. Uganda. L. H. B.

**DISTÍCHLIS** (Greek, *two-ranked*). *Gramineæ*. SALT-GRASS. MARSH SPIKE-GRASS. Rigid erect perennials, with extensively creeping wiry rootstocks: spikelets several-fld., compressed, diœcious; lemmas coriaceous, rigid, faintly many-nerved.—Species about 6, in salt marshes on the coastal regions of Amer. and in alkaline

soil of the interior. One species, *D. spicata*, Greene, with stiff, distichous involute blades and small narrow panicles is found in alkaline soil throughout the U. S. (Dept. Agric., Div. Agrost. 20:143). It is a good grass for binding soils subject to wash. Probably not in cult.

A. S. HITCHCOCK.

**DÍSTICTIS** (Greek *dis*, twice and *stiktos*, dotted; meaning obscure). *Bignoniaceæ*. Five or 6 species in Cent. and S. Amer., very similar in fl. to *Pithecoctenium*, but caps. smooth, oblong, curved, and branchlets not angular: lvs. 2- or 3-foliolate, with simple or 3-fid. tendrils: fls. large in ample terminal panicles; calyx tubular-campanulate, truncate, often splitting; corolla funnel-form-campanulate, leathery, curved; stamens inclosed; ovary with the seeds in many rows. Adapted for cult. in subtropical regions only; treatment and prop. like *Bignonia*, which see. The following species is cult. in S. Calif. *D. cinerea*, Greenm. (*Pithecoctenium cinereum*, DC.). Tall climber, grayish tomentose throughout: tendrils 3-fid.: lfts. 2-3, ovate or oval, obtuse and mucronulate or acutish, entire, 1-2 in. long: corolla purple, tomentulose outside, 2-3½ in. long and 1½-2½ in. across at the mouth. Mex.—The plant cult. under this name in Calif. is said to have white fls. and may not be the plant described above.

ALFRED REHDER.

**DISTÝLIUM** (Greek, *dis*, twice, *stylos*, style; in reference to the two slender styles). *Hamamelidaceæ*. Ornamental woody plants grown for their handsome evergreen foliage.

Evergreen trees or shrubs: lvs. alternate, short-petioled, entire, or dentate, penninerved; stipules deciduous: fls. polygamous or diœcious, apetaious, in axillary racemes, subtended by small bracts; sepals 1-5, or wanting; stamens 2-8 with short filaments; pistillate fls. with a superior stellate-tomentose ovarv. with 2 slender styles, with several stamens or without stamens: fr. a woody dehiscent caps., 2-celled, with 1 seed in each cell.—Six species in Japan, China, Himalayas and Java. Hardy only in warmer temperate regions. Prop. is by seeds and layers.

**racemòsum**, Sieb. & Zucc. Tall tree, in cult. usually shrubby: lvs. elliptic to elliptic-oblong, sometimes obovate, acute or obtusish, narrowed at the base, dark green and lustrous above, paler beneath, glabrous, 1¼-3 in. long: racemes stellate-pubescent; anthers red: caps. ovoid, 2-pointed, tomentose, ½ in. long. March, April. Japan. S.Z. 1:94. S.I.F. 2:25. I.T. 3:113.—The staminate fls. are conspicuous by the red color of their anthers. Var. *variegatum*, Carr. Lvs. bordered with yellowish white.—*D. chinense*, Hemsl. (*D. racemòsum* var. *chinense*, Franch.), a shrub with oblong-obovate lvs. ¾-1½ in. long and usually sparingly toothed above the middle from Cent. China is now possibly also in cult. H.I. 29:2835. ALFRED REHDER.

**DITTANY** is an old English word which in England often means *Dictamnus albus*, a plant of the rue family. The name is supposed to be derived from Mt. Dicte, in Crete, where the ancient dittany grew. The Cretan dittany is supposed to be *Origanum Dictamnus*, a plant of the mint family, and of the same genus with the wild marjoram. The plant commonly called dittany in the eastern United States is *Cunila origanoides*, Brit. (*C. Mariana*, Linn.), another mint, native in dry lands. See *Cunila*. It has been used as a substitute for tea, and is a gentle aromatic stimulant. All these plants yield an oil used as a mild tonic.

**DIÛRIS** (Greek, *double-tailed*, alluding to the sepals). *Orchidaceæ*. Twenty or more glabrous terrestrial orchids of Austral., rarely seen in collections in cool or warm glasshouses. The lvs. are at or near the base of the bracted st. (which is usually 1-2 ft. high), few, narrow: fls. 1 to several in a terminal raceme, conspicu-

ous from the elongated tail-like lateral green sepals; remainder of perianth yellow, purple or white, sometimes purple-blotched or -spotted; dorsal sepal remaining close to and over the column; lip 3-parted. The species are attractive or even handsome. *D. longifolia*, R. Br., has fls. several, yellow and purple, moderately large; dorsal sepal broadly ovate, the lateral long and narrow; lip as long as dorsal sepal, lobed from the base; lvs. linear, one of them often very long. *D. maculata*, Smith, is rather slender, usually under 1 ft. tall, with long-pediceled yellow much-spotted fls.; dorsal sepal erect and rigid, embracing the column at the base but open at the top; lip shorter than dorsal sepal, lobed from base: lvs. narrow. B.M. 3156. *D. punctata*, Smith. St. 1-2 ft. or more: lvs. usually 2, and 3-6 in. long; fls. 2 or 3, blue or purplish, often dotted but not blotched; dorsal sepal typically broadly ovate-oblong; lip about as long as dorsal sepal, divided to base.

L. H. B.

**DIZYGOTHECA** (Greek, in allusion to the anthers having double the usual number of cells). *Araliaceæ*. Graceful hothouse plants, grown practically exclusively for foliage; usually known as Aralia.

Usually shrubs, sometimes small trees, entirely unarmed, and differing in this from some hardy aralias: lvs. always digitate, of 5-9 lfts., varying much in adult and juvenile characters, sometimes slender and threadlike, again broad and leathery, usually long-stalked; calyx and corolla 5-parted; stamens 5, with thick anthers; ovary 10-celled; styles 10. All these fl.-characters are drawn from wild plants, as the cult. specimens are not known to flower.—Only 3 or 4 species are known in the wild state, all from the tropical isls. of the Pacific. The many names in horticultural literature are probably referable, ultimately, to some of these species, but their true position will be settled only when they flower. Here must be sought all the digitate-lyd. tender aralias of the first edition of this cyclopedia, the pinnate-lyd. species going to Polyscias. R.H. 1912, p. 491.

Dizygothecas require light rich soil, made up of equal parts of sandy loam and peat or leaf-mold. They require plenty of water and a moist warm atmosphere. Scale pests are numerous and must be kept down by frequent sponging with weak solutions of whale-oil soap, fir-tree oil or other insecticide.

The names here used are retained in the absence of specific information as to what wild species of Dizygotheca they are to be associated with. Only complete flowering material can settle this much-vexed question. All of the following are distinct horticulturally.

**Kerchoveana**, Hort. Lvs. the shape of a Ricinus, the 7-11 lfts. elliptic-lanceolate or oblong-lanceolate, with undulate and serrate margins and a pale midrib. S. Sea Isls. Certificated in England in 1881 (Gn. 19, p. 457). R.H. 1891, p. 225.—Slender-stemmed, of beautiful habit. According to Harms, perhaps better put in Pseudopanax.

**Veitchii**, Hort. Lfts. 9-11, very narrow or almost filiform, undulate, shining green above and red beneath. New Caledonia.—One of the best and handsomest species. Var. **gracillima**, Hort. (*Aralia gracilina*, Lind.). Lfts. still narrower, with a white rib. R.H. 1891, p. 226. Gn. 39, p. 565. I.H. 22:225.—Very desirable. Originally described as *Aralia gracilina* (*thin-lined*), which name has been mistaken for *gracillima* (*very graceful*).

**elegantissima**, Veitch. Petioles mottled with white; lfts. 7-11, filiform and pendulous. New Hebrides. G.Z. 21, p. 28.—Excellent. Thought by Guillemin to be the juvenile form of some Dizygotheca. Many of the greenhouse aralias have a permanent juvenile condition.

**leptophylla**, Hort. Slender plant: lfts. filiform and drooping, broadened at the extremities, deep green. Australasia.

**Reginae**, Hemsl. (*Aralia regina*, Hort.). Graceful: petioles olive, pink and brown; lfts. drooping, very narrow, not undulate. New Hebrides. I.H. 26:337.

The following greenhouse aralias, with showy lvs., probably belong to Dizygotheca, unless otherwise noted:

*A. Chabrieri*, Hort. See Polyscias.—*D. crassifolia*, Soland. See Pseudopanax.—*D. longipes*, Hort. Lvs. digitate, the lfts. oblong-lanceolate, acuminate, wavy. N. Austral.—*D. nobilis*, Hort. "A theophrasta-like plant, with closely packed, bold foliage; the lvs. oblong obovate-acuminate, undulate at the margins." Not certainly referable to Dizygotheca.—*D. Oryana*, Hort. Like *A. leptophylla*, but lfts. deeply bifid, and nerves and veins brown. S. Sea Isls.—*D. quercifolia*, Hort. Lfts. 3, sinuate: lvs. opposite. New Britain. Perhaps not of the Araliaceæ. The plant has opposite lvs.—*D. rotunda*, Hort. Lf. of a single orbicular-cordate lft. or sometimes 3-foliolate, white-toothed. Polynesia. Not certainly referable to Dizygotheca.—*D. spectabilis*, Hort.—*D. splendens*, Hort. Lvs. pinnate, the lfts. shiny green. New Caledonia.—*D. ternata*, Hort. Lvs. opposite, ternate, or 3-lobed, the lfts. oblong-lanceolate and sinuate. Not certainly referable to Dizygotheca.—*D. Victoriae*, Hort.—Polyscias. N. TAYLOR.

**DOCK.** A name applied to various species of Rumex (*Polygonaceæ*). The commonest species—growing in fields and yards—are the curled or narrow-leaved dock (*R. crispus*, Linn.) and the bitter or broad-leaved dock (*R. obtusifolius*, Linn.). These are introduced from the Old World. Several species are native. See *Rumex*.

Various species of docks and sorrels have long been cultivated as pot-herbs. Some of them are very desirable additions to the garden because they yield a pleasant food very early in spring, and, once planted, they remain for years. The Spinage dock and the Large Belleville are amongst the best kinds. The former (Fig. 1336) is the better of the two, perhaps, and it has the advantage of being a week or ten days earlier. The crisp leaves (blade 1 foot long) appear early in April, when there is nothing green to be had in the open, and they can be cut continuously for a month or more. This dock is the herb patience (*Rumex Patientia*, Linn.). It has long been an inhabitant of gardens, and it has sparingly run wild in some parts of this country. It is a native of Europe.

The Belleville (Fig. 1337) is also a European and northern North American plant. It has also become spontaneous in some of the eastern portions of the country. It is really a sorrel (*Rumex Acetosus*, Linn.). It has thinner, lighter green and longer-stalked leaves than the Spinage dock, with spear-like lobes at the base. The leaves are very sour, and will probably not prove to be so generally agreeable as those of the Spinage dock; but they are later, and afford a succession. In some countries this sorrel yields oxalic acid sufficient for commercial purposes. The round-leaved or true French sorrel (*Rumex scutatus*, Linn.) would probably be preferable to most persons.

All these docks are hardy perennials, and are very acceptable plants to those who are fond of early "greens." Some, at least, of the cultivated docks can be procured of American seedsmen. They are readily grown from seeds, and give a good produce the second year and subsequently, and often yield good leaves the first season.

L. H. B.

1336. Spinage dock.

1337. Belleville dock.

**DOCYNIA** (derivation unknown). *Rosaceæ*, subfamily *Pomeæ*. Ornamental woody plants grown for their handsome foliage and white flowers appearing in spring.

Evergreen or half-evergreen trees: lvs. alternate, entire, or serrate, sometimes slightly lobed: fls. short-stalked, in umbels before or with the lvs.; calyx densely tomentose, with lanceolate lobes; petals 5; stamens 30-50; styles 5, connate at the base and woolly; stigma 2-lobed; ovary 5-celled with 3-5 ovules in each cell: fr. a subglobose, ovoid or pyriform pome with persistent calyx.—Four species in China, Himalayas and Annam. Closely related to *Malus*, chiefly distinguished by the 3-5-ovuled cells and the 2-lobed stigma.

The species are very little known in cultivation and none of them seems to be in the trade. *D. Delavayi* has been introduced only very recently; *D. Doumeri* has been recommended as a stock for apples in tropical and subtropical countries and tried in Annam (R.H. 1904, p. 246); *D. indica*, though known for about 100 years, does not seem to be at present in cultivation either in Europe or in this country. They are adapted only for warmer temperate or subtropical regions. The fruits are more or less acid and are used for cooking; possibly they could be improved by selection and hybridization and might be developed into valuable fruit trees for warmer climates. Propagation is by seeds and possibly by grafting on apple stock.

*D. Delavayi*, Schneid. (*Pyrus Delavayi*, Franch.). Spiny tree, to 30 ft.: lvs. evergreen, ovate-lanceolate, rounded or broadly cuneate at the base, entire, glossy above, white-tomentose below, 2-4 in.: fr. ovoid, about 1 in. long. S. W. China. Franchet, Plant. Delavay. 47.—*D. Doumeri*, Schneid. (*Pyrus Doumeri*, Bois). Unarmed tree: lvs. ovate to ovate-lanceolate, entire or sparingly serrulate, white-tomentose below, 1-2½ in. long: fr. subglobose, about 2 in. across. Annam. Jour. Soc. Bot. France, 51:114, 115.—*D. indica*, Decne. (*Pyrus indica*, Wall. *D. Griffithiana*, Decne.). Small tree: lvs. ovate to oblong-lanceolate, entire or serrulate, lobed in young plants, woolly while young, finally glabrescent, 2-4 in. long: fr. subglobose, 1-1½ in. across. E. Himalayas. Wallich, Pl. As. Rar. 2:173.—The closely related *D. Hookeriana* has larger lvs. and elongated fr. Nouv. Arch. Mus. Hist. Nat. Paris. 10:15.

1338. *Dodecatheon Meadia*, the common shooting-star. (×¼)

ALFRED REHDER.

**DODÁRTIA** (Denis Dodart, physician and botanist, born in Paris in 1634). *Scrophulariææ*. One erect perennial herb related to *Mimulus*. *D. orientalis*, Linn., grows in S. Russia and W. Asia, and may be found in choice collections of outdoor herbs: fls. purplish, in terminal racemes: plant with rush-like few-lvd. branches: lvs. opposite below, alternate above, linear and entire or broader and somewhat dentate: corolla with a cylindrical or flaring tube, 2-lipped; stamens 4, didynamous, included, the anther-cells distinct: caps. subglobose, dehiscent, the many seeds somewhat immersed in the more or less fleshy placenta. July, Aug. B.M. 2199.—Apparently of minor horticultural value.

DODDER: *Cuscuta*.

**DODECÂTHEON** (Greek, *twelve gods*, old name of no application here). *Primulææ*. SHOOTING-STAR. AMERICAN COWSLIP. Small perennial herbs with cycla-

men-shaped flowers on scapes, sometimes grown in wild or hardy gardens.

Glabrous, with a tuft of ovate or oblong entire or dentate lvs. at the base, and a slender single naked scape: fls. few or many in an umbel, nodding, white, rose or purple; corolla-lobes (5) and calyx reflexed; stamens 5, attached in the throat of the short corollatube, the short filaments more or less conjoined at base and the long slender anthers connivent into a cone: fr. an oblong or somewhat cylindrical 5- or 6-valved caps.

—*Dodecatheon* is a puzzling genus to systematic botanists. It is found from Maine to Texas and from the Atlantic to the Pacific; and along the Pacific slope, from the islands of Lower Calif. to those of Bering Stra.t. In this vast region, it varies immensely. It is also found in Asia, especially northeastward. This wonderful distribution and variability is all the more remarkable if, as Gray once thought, it is all one species, because monotypic genera are considered, as a rule, to be comparatively inflexible or invariable. Pax & Knuth, on the other hand (Engler's Pflanzenreich, hft. 22, 1905), recognize 30 species. There is singular lack of agreement in the characterization of accepted species. *Dodecatheon* belongs to the same family with *Primula* and *Cyclamen*, but in a different tribe from the former, while its reflexed corolla-lobes distinguish it from most genera of its family. Many species and varieties may be expected to appear in the lists of dealers in native plants.

Shooting-star is an appropriate name. The flowers have been compared to a diminutive cyclamen, for they are pendulous and seem to be full of motion (see Fig. 1338). The stamens in *D. Meadia* and all eastern species come to a sharp point and seem to be shooting ahead, while the petals fall behind like the tail of a comet. The flowers represent every shade from pure white, through lilac and rose, to purple, and they all have a yellow circle in the middle, i.e., at the mouth of the corolla. After the flowers are gone the pedicels become erect. Some forms have all their parts in fours. There are a number of good horticultural forms offered abroad.

They require an open well-drained soil, not too dry, and moderately rich, and a shady or partially shady position. They are propagated by division or by seeds, the latter method being rather slow.

**Mèadia**, Linn. (*D. ellipticum*, Nutt. *Mèadia Dodecathea*, Crantz. *M. Dodecatheon*, Mill. *M. caroliniana*, Kuntze). Fig. 1338. Erect and strong, to 2 ft.: lvs. ovate-oblong or oblong-linear, nearly or quite obtuse, dentate-crenate or nearly entire, 1-2 in. wide, tapering into a more or less margined petiole: scape smooth, usually purple-spotted; fls. 10-20; calyx deeply parted, the parts lanceolate; corolla-lobes linear-oblong, somewhat obtuse, rose-colored and whitish at base; anthers reddish yellow, the connective body purple and broadly ovate: caps. scarcely longer than calyx, with persistent style. May, June. Woods and prairies, Pa., W. and S. B.M. 12.—This species runs

into many forms, some of which may be specifically distinct. Var. *splendendum*, Hort., is an improved form, crimson with a yellow circle. Var. *gigantæum*, Hort., is larger in all its parts: lvs. paler: fls. somewhat earlier, in some forms white. Var. *élegans*, Hort. Lvs. wider and shorter than the type: scape shorter; fls. more numerous, dark-colored. (The old generic name *Mædia* commemorates Dr. Richard Mead, 1673–1754.)

*Jeffreyi*, Van Houtte (*Mædia Jeffreyi*, Kuntze). Plant somewhat glandular-viscid: rhizome vertical and short, strong: lvs. oblanceolate, erect, entire, somewhat acute, mucronulate: scape 12–24 in. or more, bearing a many-fld. umbel; calyx-lobes lanceolate; corolla deep red-purple; connective-body of anthers very narrow or subulate at apex, colored same as stamens. Mts., Calif. and Ore. F.S. 16:1662.

*tetrandrum*, Suksdorf, has the general aspect of *D. Jeffreyi*, but the lvs. are ampler and relatively broader: roots, as in *D. Jeffreyi*, are abundant, fleshy, fibrous, persistent: roots, lvs. and scapes form a short, vertical crown: whole plant glabrous: corolla purplish, with a yellow ring near the base; segms. and stamens usually only 4: caps. circumscissile very near the apex. Mts., Wash. and Ore.

*frigidum*, Cham. & Schlecht. Plant 1 ft. or less: lvs. obovate to ovate or oblong, acutish, entire or somewhat dentate: scape much exceeding the lvs., 2–3-fld.; calyx-lobes longer than the tube; corolla-lobes oblong-linear, violet: caps. oblong, twice longer than calyx. Bering Strait to Rockies and Sierras. B.M. 5871.

*latilobum*, Elmer (*D. dentatum*, Hook. *D. Mædia* var. *latilobum*, Gray). Larger than the last: lvs. with blade 1–4 in. long, oval or ovate to oblong, repand or sparingly dentate, abruptly contracted into long-winged petioles, obtuse: fls. 2–4; calyx-lobes deltoid; corolla-lobes oblong, yellowish white: caps. but little longer than calyx, opening from the apex by valves. Wash., Ore., Idaho.

*Hendersonii*, Gray. About a foot high, glabrous, deep green: lvs. small, obovate or elliptic, 1 in. or more long, narrowed to a short petiole: fls. rather few; calyx-lobes triangular, acuminate, twice exceeding the tube; corolla-lobes dark purple with a yellow base, the staminal tube dark purple; anthers oblong, obtuse, short-apiculate; connective-body deep purple: caps. ovoid, much exceeding the calyx, dehiscent by a circumscissile apex and splitting into 10 valves. Calif. to Wash. G. 33:391.

*Clavelandii*, Greene. One to 1½ ft. tall, glabrous: lvs. pale green, thickish, spatulate-ovate, petioled: fls. 2–10; calyx-lobes ovate-lanceolate, acute, glandular; corolla-lobes purple with yellow base and a few purple spots in throat; anthers purple, the connective-body yellow: caps. oblong, circumscissile at apex. Feb.–May. S. Calif.—Fls. said to vary to pure white. Fragrant.

*radicatum*, Greene. Glabrous: root short and corm-like with fibrous rootlets: lvs. 3–5, thin, light green, oblong-spatulate, crenate or nearly entire, blade attenuate into petiole of about equal length: fls. 3–5 or more on a stout scape 8–16 in. tall; calyx-lobes lanceolate, about as long as the tube; corolla pinkish or bluish violet, the lobes oblong-linear and erect-spreading; staminal tube short; anthers purple, acute: caps. narrow-ovate, only slightly surpassing calyx-lobes. April. Wyo. to New Mex.—Recommended for alpine and rock-gardens.

L. H. B.†

**DODONÆA** (Rembert Dodoens, or Dodonæus, about 1518–1585, royal physician and author). *Sapindaceæ*. Trees and shrubs, somewhat planted in S. Fla. and S. Calif. for ornament.

Leaves alternate, without stipules, simple or pinnate: fls. small, polygamous, unisexual, often diœcious,

terminal or axillary, solitary or in racemes or panicles; sepals 5 or fewer; petals wanting; stamens mostly 8 (5–10) with very short filaments; ovary 3–6-celled, each cell 2-ovuled: caps. winged on the back of each valve.—About 50 species, mostly in Austral., a few in Afr. and in Hawaii and N. Amer. Lvs. sometimes glandular and exuding resin-like or varnish-like substance.

*viscosa*, Linn. Shrub, to 15 ft., viscid: lvs. mostly oblong, cuneate at base, entire, with resinous dots on both surfaces; fls. greenish, in short terminal or axillary racemes; sepals ovate: caps. about ¾ in. long and somewhat broader, broadly 3-winged, notched at apex, more or less cordate at base. B.R. 13:1051 (as *D. oblongifolia*).—A poorly defined plant, widely distributed in warm countries, occurring in Austral., S. Afr., in Mex., and forms of it in Fla. and Ariz. Lvs. varying from broadly spatulate to oblong to nearly or quite linear.

*Thunbergiana*, Eckl. & Zeyh. Shrubs, 6–10 ft., glabrous, much branched: lvs. lanceolate or linear-lanceolate, narrowed at base, somewhat denticulate

1339. Leaves of Dolichos. A, *D. Lablab*; B, *D. lignosus*.

and somewhat viscid: fls. green, polygamous, racemose: caps. ½ in. long, resinous and shining, 2–3-winged, as long as the stalk or longer. S. Afr.

*triquetra*, Andr. Erect shrub, the young branches flattened or very angular: lvs. oval-elliptic to oblong-lanceolate, acuminate, to 4 in. long, entire or very nearly so: fls. in short oblong compact panicles or racemes; sepals minute: caps. of *D. viscosa*, middle-sized. Austral.

*cuneata*, Rudge. Much-branched bush, usually viscid: lvs. small (usually under 1 in. long) obovate or cuneate, at the end rounded or truncate or toothed, on the sides entire or rarely obscurely toothed, short-petioled: fls. in short terminal scarcely branched racemes, or sometimes few in axillary clusters; sepals ovate-oblong: caps. of *D. viscosa*, the wings usually not very broad. Austral.

L. H. B.

**DOGBANE:** *Apocynum*.

**DOG'S-TAIL GRASS:** *Eleusine indica*.

**DOGTUOTH VIOLET:** *Erythronium*.

**DOGWOOD:** *Cornus*

**DOLICHANDRA:** *Macfadyena*.

**DOLICHODEIRA:** *Sinningia*.

**DOLICHOS** (old Greek name). *Leguminosæ*. Tropical twiners (a bush variety of *D. Lablab* is now being offered by seedsmen), of which a few forms are in cultivation, some for ornament and some for forage.

1340. Types of styles. 1, *D. Lablab*; 2, *Vigna sinensis*; 3, *V. sesquipedalis*.

Keel of the corolla narrow and bent inward at right angles, but not distinctly coiled; style bearded under the stigma, which is terminal; stipules small. For botanical distinctions between *Dolichos*, *Phaseolus* and *Vigna* see *Vigna*. The styles are points of difference (Fig. 1340). *D. japonicus*, a most worthy ornamental vine, will be found under *Pueraria*. For *D. sesquipedalis*, see *Vigna*—Perhaps 50-60 species, widely distributed. Three species of *Dolichos* are now grown in Amer.

A. Style bearded only on a ring surrounding and just below the stigma.

*biflorus*, Linn. This species is now being intro. from India, where it is frequently used as a forage plant. It differs from *D. Lablab* in having the upper lip of the calyx 2-toothed and from *D. Lablab* and *D. lignosus* in having only a ring or brush of hairs just beneath the stigma, whereas the styles of the other species are bearded on a line extending down the inner face. The seeds are small (average weight .035 gram) and rather strongly flattened. Their approximate dimensions are length  $\frac{1}{5}$ – $\frac{1}{4}$  in., width  $\frac{1}{8}$ – $\frac{1}{16}$  in., thickness  $\frac{1}{12}$  in. (2–2½ mm.).

AA. Style bearded along the inner side.

B. Seeds small,  $\frac{1}{16}$ – $\frac{1}{8}$  in. long by  $\frac{1}{16}$ – $\frac{1}{8}$  in. broad, average weight .02 grams.

*lignosus*, Linn. AUSTRALIAN PEA. Fig. 1339. Evergreen: fls. white or rosy purple: lvs. much smaller than in *D. Lablab*. A perennial rapidly growing vine, suitable for covering fences and outbuildings in warm countries; highly recommended in S. Calif. and Ariz. B.M. 380.—A form with white fls. is offered by seedsmen as *D. alba*.

BB. Seeds large,  $\frac{1}{8}$ – $\frac{1}{2}$  in. long by  $\frac{1}{4}$ – $\frac{3}{8}$  in. broad, average weight .10–.30 grams.

*Lablab*, Linn. (*D. cultratus*, Thunb. *D. purpureus*, Lindl. *Lablab cultratus*, DC.). HYACINTH BEAN. Figs. 1339, 1340, 1341. Tall-twinning (often 10–20 ft.): lfts. broad-ovate, rounded below and cuspidate-pointed at the apex, often crinkly: fls. purple or white, rather large, 2–4 at the nodes, in a long erect raceme: pods small (2–3 in. long) and flat, usually smooth, conspicuously tipped with the persistent style; seed black, mahogany or gray, in the white-fl. varieties, white, small (average weight about  $\frac{1}{4}$  gram). Tropics. B.M. 896. B.R. 830. A.G. 14:84.—Cult. in this country as an ornamental climbing bean, but in the tropics the pods and seeds are eaten. Annual. It is easily grown in any good garden soil. Like common beans it will not endure frost. It is very variable. White-fl. and dwarf bush forms are now offered by seedsmen. A form with white fls. and very large growth is known among horticulturists as *D. giganteus* (Fig. 1342).

1341. Calyx cups and styles of *Dolichos*. 1, *D. lignosus*; 2, *D. Lablab*.

*D. pseudopachyrhizus*, Harms, recently intro. into some of the European gardens from Trop. Afr., is a perennial form with a large tuberous rootstock: sts. long, round or angular: lvs. long-stalked, 3-foliolate: lfts. very variable in shape, the lateral often ovate or elliptic and the terminal broadly rhomboid,  $3\frac{1}{4}$ –8 in. long,  $2\frac{1}{2}$ –7 in. broad: fls. small, chiefly violet-blue, in racemes  $\frac{1}{2}$ –1½ ft. long.

GEO. F. FREEMAN.

**DOMBEYA** (after Joseph Dombey (1742–1795)

French botanist and companion of Ruiz and Pavon in Peru and Chile). Syn. *Assonia*, *Astrapæa*, *Sterculiaceæ*. Shrubs or small trees of continental Afr., Madagascar and Seychelles, sometimes plan. in Afr. and Calif.: lvs. often cordate, palmately nerved, frequently lobed: fls. rosy or white, numerous, in loose axillary or terminal cymes, in umbels, or crowded into dense heads, often very showy; calyx 5-parted, persistent; petals 5; stamens 15–20, 5 sterile, the remainder shorter, united into a tube or cup; ovary 2–5-celled; stigmas 5: fr. a loculicidal caps.—Probably 100 species, many new kinds having been made known recently with the opening of Trop. Afr. The dombeyas are yet little known in this country, although some of them promise well for lawn and park planting far south.

*natalensis*, Sond. Distinguished by its cordate, acute lvs. and the narrowly awl-shaped lfts. of the involucre: lvs. long, petioled, somewhat angular, toothed, with minute stellate pubescence, 5–7-ribbed: umbels 4–8-fl. Natal.—Cult. in S. Fla. and North under glass. Very rapid-growing, foliage poplar-like: fls. pure white, large, sweet-scented; a very good winter-blooming plant in S. Calif.

*spectabilis*, Bojer. Small tree: lvs. cordate, orbicular or oblong, acute, undulate, 5–9-nerved, rough above and rusty or whitish pubescent beneath, the petioles downy: fls.  $\frac{3}{4}$  in. across, white, in many-fl. much-branched axillary and terminal cymes; sepals lanceolate, shorter than corolla; petals roundish; stamens united only at base. E. Trop. Afr.—A plant under this name is catalogued in this country as “a tall shrub with straw-colored and pink fls.”

*acutángula*, Cav. (*Astrapæa tilix-folia*, Sweet). Low tree or shrub, with lvs. crowded at ends of branches: lvs. thin, round-cordate, nearly glabrous, palmately 3–5-lobed: fls. in 2-parted cymes; bracteoles large, ovate, falling; sepals  $\frac{1}{3}$  in. or less long, reflexing; petals white or reddish,  $\frac{1}{2}$  in. long, oblique-obovate; stamens 18, being exceeded in length by the staminodia; ovary densely tomentose, and styles free at top only. Mauritius and Bourbon. B.M. 2905 (form with entire lvs.).

1342. *Dolichos Lablab* (form *giganteus*). (×½)

*punctata*, Cav. Tree, the young parts hairy: lvs. smooth and firm, orbicular and deeply cordate, acute, 3–4 in. long, obscurely crenate: fls. 10–20 in a simple umbel that has a peduncle 2–3 times the length of the petiole; sepals linear-lanceolate, reflexed; petals rather longer than sepals, obdeltoide; ovary tomentose. Mauritius and Bourbon. Intro. in S. Calif.

*nairobensis*, Engler. Shrub or tree with terete branches that become glabrous or nearly so: lvs. ovate-cordate, acuminate, somewhat 3-lobed, irregularly crenate, 7-nerved, hairy, and tomentose beneath: fls. on long hispid pedicels in an umbel; bracteoles ovate-lanceolate; sepals lanceolate, becoming reflexed, tomentose outside; petals oblique and obtuse, scarcely

exceeding petals; staminodia narrowly spatulate; ovary tomentose. Nairobi.

**Wallichii**, Benth. & Hook. (*Astrapæa Wallichii*, Lindl.). Tree, to 30 ft.: lvs. large, velvety, cordate, angularly lobed, with leafy stipules: fls. scarlet (pink?), in drooping umbels, the peduncles long and hairy. Madagascar.—A very showy plant when in bloom.

*D. Burgessii*, Gerrard. Lvs. pubescent, cordate, but with 2 deep, wide cuts, and 2 shallow ones besides the basal one: fls. numerous, large, white, rosy at center and along veins; petals rounded. S. Afr. B.M. 5487.—*D. calantha*, Schum. Shrub, 10-12 ft.: lvs. large (1 ft. across), 3-5-lobed, coarsely toothed, cordate at base, pubescent above and tomentose beneath, with long petioles: fls. rose-colored, 1½ in. across. British Cent. Afr. B.M. 8424.—*D. Cayeuxii*, Hort., is a hybrid of *D. Mastersii* and *D. Wallichii*: fls. beautiful pink in pendulous, many-fl. umbels: lvs. cordate, acute, dentate, with long petioles.—*D. Côtia*, Baill. Tall tree: lvs. cordate or somewhat 3-lobed, 6 in. long and nearly as broad, toothed or crenulate, pubescent beneath: fls. lilac-rose, 2½ in. across. Madagascar. R.H. 1911:84.—*D. Davaei*, Hort., is a hybrid of *D. spectabilis* and *D. natalensis*: fls. rose-colored; also a white-fl. form (var. alba). R.H. 1912, p. 178-9.—*D. Mastersii*, Hook. Shrub, 4-5 ft. high: lvs. velvety, heart-shaped, serrate: fls. fragrant, white, with thinner veins of rose than in *D. Burgessii*; petals acute. Trop. Afr. B.M. 5639.—*D. viburniflora*, Bojer, has very numerous white fls. with narrower petals than any here described: lvs. cordate, 3-lobed, the cuts not so wide as in *D. Burgessii*. Comoro. B.M. 5458.

L. H. B.†

**DÓNDIA**: *Hacquetia*.

**DOÛDIA** (after Samuel Doody, London apothecary). *Polypodiaceæ*. Greenhouse ferns.

Sori curved, placed in one or more rows between the midribs and the margins of the pinnæ: lvs. rigid. A genus of diminutive ferns related to Woodwardia.—Species 4 or 5. Ceylon to New Zealand.

All doodias, except *D. blechnoides*, are of dwarf habit, and are useful for fern-cases and for edgings of window boxes. Cool and intermediate temperatures are best. They are excellent for forming an undergrowth in coolhouses, as they seldom are infested with insects, and endure fumigation. Schneider recommends three parts of peat and one of silver sand. Loam does not help, but a little chopped sphagnum does. They are very sensitive to stagnant water, and do not like full exposure to sunlight. Always propagate by spores, but division is possible.

A. *Lvs. pinnatifid.*

**áspera**, R. Br. Lvs. 6-18 in. long, 2-4 in. wide, pinnatifid, narrowed gradually below; sori in 1 or 2 rows. Temp. Austral.—Crested varieties occur in cult.

AA. *Lvs. pinnate in the lower half.*

**mèdia**, R. Br. Lvs. 12-18 in. long, with pinnæ 1-2 in. long, the lower one gradually smaller. Austral. and New Zealand.—*D. Kunthiana*, Gaud., from the Hawaiian Isls. has close median pinnæ. *D. superba*, Hort., is a larger garden form.

**caudata**, R. Br. Lvs. 6-12 in. long, with pinnæ about an inch long, the spore-bearing ones shorter; apex often terminating in a long point. Austral. and New Zealand.

**blechnoides**, Cunn. Lvs. 18 in. long; lf.-blades 15 in. long, 6 in. broad, broadest at the middle, the lowest pinnæ considerably narrowed; margins serrate: sori in an irregular row near midrib. New S. Wales.

L. M. UNDERWOOD.

R. C. BENEDICT.†

**DORÈMA** (*dorema*, a gift, an allusion to the gift of gum ammoniac). *Umbelliferae*. About 4 odd large perennial herbs of S. W. Asia, yielding gum-resins, likely to be met with in collections of economic plants. Usually glaucous, with pinnately decomposed lvs., and small white or yellow fls. in close woolly umbels: calyx-teeth wanting or nearly so; petals ovate: fr. ovate, plano-compressed. *D. Ammoniacum*, D. Don, an erect fleshy-stemmed herb to 7 ft., with a few lvs. near the base and bracts above, yields gum-ammoniac, a medicinal product. This resin exudes on the sting of insects, occurring in yellowish brown "tears" or drops;

it has a balsamic odor and bitter unpleasant taste. The plant is native in Persia and Afghanistan. Other species yield similar exudation.

**DORONICUM** (Latinized Arabic name). *Compósitæ*. LEOPARD'S BANE. Hardy herbaceous plants, 1-2 feet high, with yellow many-flowered heads.

Stems little branched or not at all: lvs. alternate, radical ones long-stalked, st.-lvs. distant, often clasping the st.: heads mostly one on a st. and 2-3 in. across, borne high above the basal crown of foliage, from April to June.—From 20-30 species, natives of Eu. and Temp. Asia. The genus is allied to *Arnica* and distinguished by the alternate lvs. and by the style.

The plants are of easy culture in rich loam except *D. cordifolium*, which is an alpine species. The flowers are numerous and good for cutting. *Doronicums* have been strongly recommended for forcing.

A. *Root-lvs. not notched at the base, ovate.*

**plantagineum**, Linn. Glabrous, but woolly at the neck, with long, silky hairs: root-lvs. ovate or oval, wavy-toothed; st.-lvs. nearly entire, the lower ones narrowed into a petiole and not eared, the upper ones sessile, oblong, acuminate: rhizome tuberous, roundish, or creeping obliquely: stalk of the root-lvs. about 3 in. long: typically about 2 ft. high. Sandy woods of Eu. G.C. III. 17:229. J.H. III. 55:109. Gn. 60:151. Var. **excelsum**, Hort. (*D. excelsum*, Hort. *D. "Harpur Crew,"* Hort.), is more robust, grows about 5 ft. high and is probably more cult. than any other kind of *doronicum*. Fls. sometimes 4 in. across. Gn. 47, p. 269; 28:512; 38:437. G.C. II. 20:297. G. 19:441; 27:225. Gn. W. 24:221.

**Clusii**, Tausch. (*Arnica Clusii*, All.) Lvs. ovate or oblong; st.-lvs. half clasping, with distant teeth or many small ones. One subvariety has long, silky hairs on its lvs., while another has none. Swiss and Austrian Alps.—"Soft, downy foliage," J. W. Manning. "Grows 2 ft. high," Woolson. "Larger and later fls. than *D. caucasicum*," Ellwanger and Barry.

AA. *Root-lvs. notched at the base, heart-shaped.*

B. *Root tuberous.*

**Pardaliánches**, Linn. Hairy: lvs. toothed; lower st.-lvs. eared at the base of the stalk, subovate, upper ones spatulate-cordate, highest ones cordate-clasping, acute. Woods of lower mountains of Eu. G. 22:499.—While all species are typically 1-fl., any of them may have now and then more than 1 fl. on a st., and this species particularly may have 1-5 fls.

BB. *Root not tuberous.*

**caucasicum**, Bieb. Glabrous except as noted above: lvs. crenate-dentate, lower st.-lvs. eared at the base of the stalk, the blade subcordate, highest ones cordate to half-clasping; lvs. near the infl. linear-lanceolate. Shady woods of Caucasus, Sicily, etc. B.M. 3143. Gn. 28 p. 512., which shows sts. with 1 fl. and 1 lf.—Fls. 2 in. across.

**cordifolium**, Sternb. (*D. Columnæ*, Tenore). Glabrous, the st. very fibrous toward the base, scarcely 5 in. tall: radical lvs. cordate-kidney-shaped, the upper lvs. st.-clasping: heads solitary on the sts., the small lvs. near it ovate-lanceolate, acuminate. An alpine species from S. E. Eu. and adjacent Asia.

**austriacum**, Jacq. A trifle hairy: lvs. minutely toothed, lower st.-lvs. spatulate-ovate, abruptly narrowed at the base, half-clasping, highest ones cordate-clasping, lanceolate. Subalpine woods, Eu.

*D. draytonense*, Hort., is a list name, not referable to any known species. It seems not to occur in horticultural or botanical literature.—*D. magnificum*, Hort., described as a "very attractive perennial with large yellow fls. somewhat like a single sunflower," is also doubtful. It may be *D. plantagineum* var. *excelsum*.

WILHELM MILLER.  
N. TAYLOR.†

**DORSTÈNIA** (Theodor Dorsten, professor of medicine at Marburg, died 1539). *Moraceæ*. About 50 tropical herbs or small shrubs, remarkable for the dilated receptacle in which the unisexual fls. are borne, being imbedded in the surface. Both staminate and pistillate fls. are without perianth; stamens 1-4; ovary 1-loculed; stigma 2-lobed. Dorstenias are easily grown in warm shady glasshouses. The plants are not in the American trade, but they are often grown in botanical establishments to illustrate morphology. The fig is a hollow receptacle formed of the axis of the fl.-cluster; the dorstenia bears a flattened or cup-like receptacle, and is an intermediate stage between the fig and other plants. One of the common species is *D. Contrajerva*, Linn. (Fig. 1343), which is native to Trop. Amer.: fls. on a scape; lvs. round-cordate, palmately lobed or parted; the segms. ovate or oblong and more or less toothed: receptacle irregularly rectangular, peltate: rhizome cylindric, nodose. Mex., W. Indies, Venezuela, Colombia.

L. H. B.

**DORYÁLIS:** *Aberia*.

**DORYÁNTHE** (Greek, *spear-flower*; the flowering stem 8 to 25 feet high, crowned by a spike of flowers 3 feet high). *Amoryllidaceæ*. Great desert plants from Australia, with 100 or more leaves 6 feet long when full grown, being impressive for large conservatories, or for open ground in the South, where they will stand slight frost.

The representative in Austral. of the American *Furcraea* and *Agave*: lvs. in a dense basal rosette, those on the st. much reduced: fls. large, bright red (often replaced by bulblets), in a large thyrselike or paniced infl.; perianth with little or no tube, the segms. long and falcate; stamens 6, attached at base of perianth, the filaments filiform: fr. a turbinate caps., 3-valved.—Three or 4 species. Little known under glass, as they require too much room. A plant of *D. Palmeri* remained at Kew 16 years before flowering. Plants of doryanthes are propagated by suckers, which are produced only after flowering. The process is very slow. The young plants must be repotted for several years until they have attained a large size. They are said to do best in a compost of loam and leaf-mold in equal parts.

**excelsa**, Correa. **SPEAR-LILY**. Lvs. sword-shaped, not ribbed, smooth, entire, with a very narrow cartilaginous margin, lower ones recurved, others erect: scape clothed with lanceolate lvs., which sheath the st. at their base; fls. in a globular head, deep crimson or maroon inside and out (there is a white-fl. form). B.M. 1685. R.H. 1865, pp. 466, 471; 1891, p. 548. G.C. II. 11:339. Gn.W. 16:681. G.W. 9, p. 521. H.F. II. 7:136.

**Pálmeri**, W. Hill. Even more gigantic than *D. excelsa*: lvs. longer and broader, slightly ribbed and a longer brown point: fls. in a thyrsoid panicle, bright scarlet outside, whitish within. B.M. 6665. F.S. 20:2097. R.H. 1891:548. G.C. II. 17:409. G.W. 12, p. 222. New shoots are said to be produced at the base, which bloom in one or more years.

*D. Guilfoylei*, F. M. Bailey, **QUEENSLAND-LILY**, is a large and fine species from N. Queensland, perhaps a form of *D. Palmeri*:

lvs. 9 ft. long, over 8 in. wide: fls. rich crimson, 4 in. long. It yields a good fiber. Gn. 44, p. 69. G.C. III. 45:383.

WILHELM MILLER.

L. H. B.†

**DORYÓPTERIS** (Greek, *lance-fern*). *Polypodiaceæ*. Small pot ferns with oddly pretty leaves.

Leaves with continuous marginal sori and copiously anastomosing veins.—About 20 species, in warm countries. Sometimes joined to *Pteris*, which see for culture. Not to be confused with *Dryopteris*.

**palmata**, J. Smith. Lvs. 4-9 in. each way, with 5 or more triangular lobes or the fertile still more divided; ribs black. W. Indies to Brazil.—Sometimes considered to be a variety of *D. pedata*, Fée.

**nóbilis**, J. Smith. Larger: lvs. sometimes 1 ft. long, pedately bipinnatifid; ribs chestnut. S. Brazil.

*D. decipiens*, with lvs. resembling a geranium lf., 3-6 in. each way, is sometimes cult., as is *D. decora*, with more divided lvs. Both are natives of the Hawaiian Isls.

L. M. UNDERWOOD.

**DOSSINIA** (E. P. Dossin, Belgian botanist, 1777-1852). *Orchidaceæ*. One species of terrestrial orchids, allied to *Anæctochilus*, but lacking the bearded fringe on the lower part of the labellum. This species may possibly be cult. by a few amateurs who are skilled in the cult. of dwarf greenhouse foliage plants.

*D. marmorata*, C. Morr. (*Anæctochilus Lowei*, Hort.). Lvs. golden-veined or marbled, 4-5 in. long, elliptic: scape pubescent, 10 in. high; spike 5 in. long, with many white, pubescent fls. Java. F.S. 4:370.—There is a stronger-growing var., with foliage better colored.

**DOUGLÁSIA** (after David Douglas, the Scotch botanist, who explored California, Oregon and British Columbia in 1823 and 1829). Incl. *Arètia*. *Primulaceæ*. Low tufted perennial herbs, one of which is used in alpine gardening.

The genus is closely allied to *Androsace* and *Primula*, but in those two genera the lvs. come from the root, while *Douglasia* has branches, though very short ones, which are densely clothed with lvs. *Douglasia* has a corolla-tube equaling or exceeding the calyx, somewhat inflated toward the top, with 5 scales or crests beneath the sinuses; calyx 5-lobed, persistent; stamens 5, included; ovary 5-ovuled: fr. a turbinate 1- or 2-seeded caps.—Seven or 8 species in mountains of Eu., and W. N. Amer., considered to be 6 by Pax & Knuth in Engler's

*Pflanzenreich*, hft. 22 (1905). The fls. are yellow in *D. Vitaliana*, which is the cult. species, but otherwise rose-purple. The plants require the treatment accorded to other alpine; see *Alpine Plants*, Vol. I.

**Vitaliana**, Hook. f. (*Primula Vitaliana*, Linn. *Androsace Vitaliana*, Reichb. *Arètia Vitaliana*, Lodd. *Gregoria Vitaliana*, Duby). Height 2 in.: sts. numerous, prostrate, somewhat woody: branches denuded of lvs. at the base, but at the tips clothed with overlapping linear entire pilose lvs.: fls. nearly stalkless, solitary or 2 or 3, yellow, rather large; corolla-tube 2 or 3 times longer than the calyx, the lobes ovate-lanceolate, obtuse. Alps, Pyrenees. L.B.C. 2:166.

Some of the American douglasias, all with rose or purple fls. are sometimes listed by foreign specialists in alpine.—*D. arctica*, Hook. Glabrous: lvs. ciliate with short and simple hairs, apex obtuse: fl. 1 on a scape; corolla-tube about equaling calyx: plant loosely caespitose. High arctic Amer.—*D. dentata*, Wats. Like *D. nivalis* and by some considered to be a form of it, but coarser and

1343. *Dorstenia Contrajerva*. (×¼)

with broader often spatulate lvs. which are entire and sparingly denticulate. Cascade Mts., Wash.—*D. laevigata*, Gray. Mature lvs. coriaceous, the margin smooth or rarely minutely ciliate, blade oblong or oblong-lanceolate and obtuse: fls. 2-5; corolla-tube almost twice as long as calyx. Ore., Wash.—*D. montana*, Gray. Mature lvs. prominently ciliate on the margins, destitute of forked hairs, the blade very small and linear or lanceolate: fls. single, the corolla-tube less than the calyx or just equaling it. Mts., Wyo., Mont. Runs into several forms, 2 of which have been described as species (*D. biflora*, Nelson and *D. or Androsacea uniflora*).—*D. nivalis*, Lindl. Mature lvs. covered with minute 2-3-forked pairs, margins not ciliate, blade linear and usually entire: fls. 3-7, the corolla-tube hardly exceeding the calyx. Columbia River.

L. H. B.†

DOUGLAS SPRUCE: *Pseudotsuga Douglasii*.

**DOWNÍNGIA** (after Andrew Jackson Downing, famous American pomologist and landscape gardener). *Campanulacæ*; or *Lobeliacæ* when this family is kept distinct. Low herbs, much branched, sometimes grown as garden annuals; flowers blue with white or yellow markings or blotches.

Leaves alternate, entire, passing above into bracts: fls. in the axils of the lvs. or upper sessile bracts; corolla 2-lipped, the upper lobes much narrower than the 3 lower ones; tube of stamens free from the corolla: seeds numerous, small, oblong to spindle-shaped, in a very long linear caps. that bears at its apex the leafy linear calyx-lobes and is dehiscent lengthwise by 1-3 valves or fissures.—Six to 8 species, mostly in Calif. (1 in Chile), usually in moist places and margins of spring pools, sometimes in salty marshes or in mountains. Rafinesque's name *Bolelia* (anagram of *Lobelia*) is older, but is discarded by the list of "nomina conservanda" of the the Vienna code. The plants are little known in American gardens. They are easily grown annuals, and are said to make interesting pot-plants. The species are often not well distinguished, and some of them may be color forms. The plants grow about 6 in. high, and have been recommended for edgings.

**pulchélla**, Torr. (*Clintònia pulchélla*, Lindl.). Erect or ascending, 2-10 in., usually simple: lvs. oblong-ovate to linear,  $\frac{1}{2}$  in. long, obtuse: fls. deep blue, the center of lower lip yellow with a white border, and marked with violet and yellow in throat; lower lip with 3 roundish apiculate lobes; upper lip deeply 2-cleft with spreading oblong-lanceolate segms. May, June, in Calif. B.R. 1909. R.H. 1861: 171. G.W. 15, p. 213. R.H. 1895, p. 19, shows its straggling habit as a pot-plant. Many of the branches fall below the top of the pot.

**élegans**, Torr. (*C. elegans*, Douglas). St. usually simple, 4-7 in.: lvs. ovate to lanceolate: the broad lip moderately 3-lobed; the 2 divisions of the smaller lip lanceolate, parallel; lower lip sky-blue with darker veinlets and the main part white with 2 green or yellowish spots; the throat often purple-spotted and yellow-lined. May. Calif. B.R. 1241.

L. H. B.†

DOXÁNTHA CAPREOLÁTA, Miers: *Bignonia capreolata*.

**DRÁBA** (Greek name for a cress). *Cruciferae*. **WHITLOW-GRASS**. One of the important groups of spring-flowering plants for the alpine garden.

A large and widely scattered genus of tufted hardy annual or perennial herbs, with stellate hairs: lvs. often in a rosette, mostly uncut: scapes or sts. leafy or not; racemes short or long; fls. without bracts, small, white, yellow, rosy or purple; stamens 6; fr. an oval, orbicular or linear flat pod with several to many marginless seeds in 2 rows in each cell; cotyledons accumbent.—Some 150 species in temperate and arctic regions of the world, many of them in mountains. Many species occur in the lists of alpine gardeners. They are more or less alyssum-like.

Drabas are very pretty dwarf compact alpine plants, with small but numerous flowers admirably adapted for the rockery or front part of a sunny border. They require a sunny position and an open soil. It is important that they be well matured by the autumn sun. The

plant forms a dense little rosette of lvs., and has a neat appearance at all times. In spring, drabas are thickly covered with their little flowers and when planted in masses are decidedly effective. Propagation is chiefly by division; also by seed, which may be sown in the fall if desired. (J. B. Keller.)

A. Fls. rose or purple.

1. **pyrenaica**, Linn. **ROCK BEAUTY**. Height 2-3 in.: lvs. wedge-shaped, 3-lobed at apex: fls. white at first, changing to rosy pink. May. Mts., S. Eu. B.M. 713.—Said to be easily prop. by cuttings. This is *Petrocallis pyrenaica*, R. Br., under which name it will be found again.

2. **violacea**, DC. St. woody at base, branched: 6-12 in.: lvs. obovate-oblong, obtuse, equally woolly

1344. *Draba Dedeana*.

on both sides: scapes leafy; petals obovate, dark purple. Andes of Ecuador at elevations of 13,000-15,000 ft. B.M. 5650.

AA. Fls. white (sometimes yellowish in No. 6).

B. Plants biennial or annual.

3. **cinerea**, Adams. St. nearly simple: lvs. oblong-linear, stellate pubescent: petals twice longer than calyx: pods oblong, pubescent, shorter than the pedicel. Early spring. Siberia.

BB. Plants perennial.

c. Lvs. rigid.

4. **Mawii**, Hook. Forming low, densely tufted, bright green patches: st. much branched, densely clothed with spreading, rosulate lvs.: lvs. linear-oblong, obtuse, bristly, with a prominent midrib below: scape very short, woolly, 2-4-fl., very short-pedicelled; petals thrice as large as the sepals, obcordate, white: pods ellipsoid, compressed. Spain. B.M. 6186.

5. **gigas**, Stur (properly *Árabis Carduchorum*, Boiss.). Lvs. rosulate and rigid, linear and obtusish, ciliate: scape 1 in. or less, the fruiting raceme short and contracted; fls. white: fr. glabrous, elliptic-linear, the style very short, the valves 1-nerved and keeled. Armenia.

cc. Lvs. not rigid.

6. **fladnizensis**, Wulf. (*D. androsacea*, Willd. *D. Wahlenbergii*, Hartm. *D. lappónica*, Willd.). Plant 2-3 in., much branched at base: lvs. rather loosely rosulate, oblong-linear to lanceolate, ciliate, usually somewhat villous or stellate-pubescent, less than  $\frac{1}{2}$  in. long: scape usually glabrous or only slightly villous; fls. sometimes yellowish: pods elliptic-oblong to ovate-lanceolate, not hairy. Arctic regions and Cent. Eu.

XXXVII. *Dracæna Goldieana*, a "foliage plant" from tropical Africa.

## AAA. Fls. yellow.

## B. Lvs. rigid, keeled, ciliate.

7. *aizoides*, Linn. Cespitose, 2-3 in.: lvs. linear and acutish; scape glabrous, the raceme elongating in fr.; petals yellow, twice exceeding the calyx; anthers about equaling the petals: fr. oblong-elliptic, glabrous or setulose; style as long as the ptd is wide. March. Cent. and S. Eu.—B.M. 170. Variable.

8. *Aizodon*, Wahl. About 3 in. high: lvs. broad-lanceolate, strongly ciliate: scape hairy, with sulfur-yellow fls., the filaments being paler or greenish. April. Eu.—Diverse in habit.

9. *Dedeana*, Boiss. & Reut. Fig. 1344. Densely cespitose: scape and pedicels pubescent: lvs. oblong-linear, attenuate at base: petals broadly obcordate-cuneate; stamens scarcely longer than calyx: fr. ellipsoid or ovoid. Spain.—In habit like *D. aizoides*; fls. paler yellow.

10. *cuspidata*, Bieb. Cespitose: lvs. linear-acute: scape villous or woolly, the fruiting raceme short; petals yellow, twice exceeding the calyx; anthers equaling the petals: fr. lanceolate and somewhat turgid, setulose. Asia Minor.—Aspect of *D. aizoides*, but scape shorter and pod somewhat inflated.

11. *olympica*, Sibth. (*D. bruniaefolia*, Stev.). Densely and broadly cespitose, about 4 in. high: lvs. narrowly linear, somewhat keeled: petals deep golden, twice as long as the calyx and stamens: fr. small, turgid-compressed; style very short. June. Greece, Orient.—Runs into many forms.

12. *rigida*, Willd. (*D. bryoides*, DC.). Powdered: lvs. minute, and very short, oblong-linear and keeled, obtusish, the margin more or less ciliate: scape glabrous, bearing a rather long raceme; petals deep golden yellow, much exceeding calyx: fr. elliptic or nearly linear. Caucasus, Armenia.

13. *imbricata*, Meyer. Very dwarf, much powdered: lvs. very small, oblong, obtuse, 3-sided, ciliate, densely imbricate: raceme nearly sessile, glabrous, 3-5-fld.; petals deep golden, twice exceeding the calyx; filaments exceeding calyx: fr. ovate-orbicular, glabrous, nearly plane; style very short. Caucasus.—An excellent little rock alpine.

## BB. Lvs. not rigid or keeled.

14. *hispida*, Willd. (*D. tridentata*, DC.). About 3 in. high: lvs. obovate, narrowed into a long petiole, obscurely 1-3-toothed at the apex, somewhat bristly: scape not hairy; petals yellow, cuneate, retuse, twice longer than calyx: fr. oblong-linear, not hairy. Russia, Caucasus.

15. *alpina*, Linn. Densely cespitose, with a much-branched caudex: lvs. lanceolate or oblong, obtuse or acute, pubescent: flat: scape more or less hairy: pods oblong to ovate; style very short. April. Greenland, N. Eu., Asia.

16. *aurea*, Vahl. Doubtfully perennial or biennial, pubescent throughout with stellate hairs, the caudex simple or little branched: lvs. oblanceolate to lanceolate, to 2 in., entire or remotely serrate: petals bright yellow to almost white: pods lanceolate to linear, acute, often twisted. New Mex., and Ariz. in mountains and north. B.M. 2934.

*D. borealis*, DC. Fls. white: stellate-pubescent, more or less cespitose, st. 2-12 in., simple or sparingly branched: lvs. ovate to oblong-ovate, flat,  $\frac{1}{2}$  in. or less: style short and stout. Brit. Col. to the high N., Japan.—*D. elata*, Hook. f. Fls. yellow: tall biennial, the st. about 1 ft. high from the previous year's rosette of spatulate lvs. Himalayas.—*D. frigida*, Saut. Fls. white: scape about 2-lvd., loosely pubescent: lvs. lanceolate or elliptic, stellate-tomentose: fr. oblong, glabrous, the style very short or almost none. Alps.—*D. Gilliesii*, Hook. & Arn. Fls. white,  $\frac{1}{2}$  in. or less across: tufted perennial, 1-10 in., variable: lvs. ovate-oblong, coarsely toothed: fls. few to many in an erect raceme. Chile. B.M. 7913. Gn. 63, p. 243.—*D. grandiflora*, Hook. & Arn. Fls. white, in racemes: plant small and tufted, with tomentose lvs. oblong-spatulate. High Andes. Gn. 63, p. 242. Showy; hardy in England.—*D. Salamoni*,

offered abroad, is described as "very close, compact tufts, white fls."—*D. verna*, Linn. WHITLOW-GRASS. A winter annual, widely naturalized from Eu., with white fls., bifid petals, oblong-obovate to oblanceolate rosette lvs., slender scapes 2-6 in., and glabrous round-oval to oblong pods.

L. H. B.†

DRACÆNA (*femalé dragon*; the dried juice supposed to resemble dragon's blood). *Liliacæ*. DRACENA. Ornamental hothouse or stove plants, frequently with variegated leaves.

Often arborescent, with sword-shaped or broad lvs. mostly crowded at the summit of the st.: fls. clustered in panicles or heads, greenish-white or yellowish; perianth salver-form or campanulate; lobes 6, spreading; stamens 6: fr. a 3-celled berry. Differs from *Cordyline* in having larger fls., and solitary instead of many ovules in each cell of the ovary.—About 40 tropical woody plants, a few being in cult. See Baker, Journ. Linn. Soc., vol. 14, for a monograph of the genus.

*Dracena Draco*, of the Canaries, is the dragon tree. It reaches a height of 30 to 60 feet, branching when of great age. The dragon tree of Teneriffe, famous for centuries, was 70 feet high, and one of the oldest of known trees. See *Cordyline* for other names not found in this article; also for culture.

The following key to the cultivated species of both *Dracena* and *Cordyline* is based upon the lvs.

## INDEX.

Børhavii, 1.	Hookeriana, 3.	Rumphii, 3.
deremensis, 5.	Knerkii, 4.	Sanderiana, 7.
Draco, 1.	latifolia, 3.	thaloides, 7.
fragrans, 4.	Lindenii, 4.	umbraculifera, 2.
Godseffiana, 8.	Massangeana, 4.	variegata, 3.
Goldieana, 6.	Rothiana, 4.	Victoria, 4.

## KEY TO THE SPECIES.

- A. Lvs. long and sword-shaped, sessile.
  - B. The lvs. glaucous beneath, 2-5 in. wide.....C. indivisa
- BB. The lvs. with both faces similar, narrower.
  - C. Of mature plants narrow (6-15 lines broad).....C. stricta
  - CC. Of mature plants broader (1-2 in.).
    - D. Margins green.
      - E. Color of lvs. glaucous-green, costate,  $1\frac{1}{2}$ -2 ft. by 15-21 lines.....D. Draco
      - EE. Color of lvs. green, costate, undulate below, 2-3½ ft. by 1½-2 in.....D. umbraculifera
      - EEE. Color of lvs. green, costa obscure, 3-4 ft. by 18-18 lines.....C. australis
    - DD. Margins white-pellucid.....D. Hookeriana
- AA. Lvs. oblanceolate, broadly petioled or sessile.
  - B. Size of lvs. 3-4 in. by 1½-2 in., opposite or whorled.....D. Godseffiana
- BB. Size of lvs. 12-15 in. by 18-21 lines, alternate.....C. rubra
- BBB. Size of lvs. 1½-3 ft. by 2-4 in., alternate.
  - C. Pedicels 1-1½ lines long; perianth 5-7 lines long.....D. fragrans
  - CC. Pedicels 1½-2 lines long; perianth 7-8 lines long.....D. deremensis
- AAA. Lvs. ovate, lanceolate, or elliptical; petioles narrow.
  - B. The lvs. 4-8 in. by 2-2½ in., oblong-falcate, green.....C. Haageana
- BB. The lvs. 7-8 in. by 4-5 in., oblong, white-spotted.....D. Goldieana
- BBB. The lvs. 7-10 in. by ½-1½ in., lanceolate, white-margined.....D. Sanderiana
- BBBB. The lvs. 10-18 in. by 1-3½ in., elliptical.....C. terminalis

1. *Draco*, Linn. DRAGON-TREE. Arborescent (60 ft. high), branched: lvs. very numerous, crowded, sword-shaped, erect or the outer recurved ( $1\frac{1}{2}$ -2 ft. x  $1\frac{1}{4}$ -1¾ in.), scarcely narrowed below, long-attenuate at the apex, glaucous-green: pedicels 3-6 lines long; bracts minute, lanceolate: perianth 4 lines long, green-

ish; filaments flat; berries orange. Canary Is. B.M. 4571. R.H. 1869, p. 416; 1880, p. 196. G.C. II. 14:749. G.W. 12:233. J.F. 2, pl. 124.—Fine for conservatory. *D. Boerhavi*, Tenore, is a garden form, with elongated lvs., all recurved.

2. *umbraculifera*, Jacq. Arborescent (3–10 ft. high), simple; lvs. very numerous, crowded, sword-shaped (2–3½ ft. x 1½–2 in.), outer recurved, all green and shining, attenuate at the apex, scarcely narrowed toward the conspicuously undulate base, costa distinct on both faces; pedicels 4–6 lines long; bracts minute, deltoid; perianth large, 2 in. long, white, tinged with red; filaments filiform. Mauritius. L.B.C. 3:289.

3. *Hookeriāna*, Koch (*C. Rumphii*, Hook. *D. Rumphii*, Regel). Trunk 3–6 ft. high, sometimes branched; lvs. numerous, densely clustered, sword-shaped (2–2½ ft. x 1½–2 in.), outer reflexed, all long-attenuate at the apex, scarcely narrowed below, margin white-pellucid, lower face concave, indistinctly costate beneath; bracts 1½–3 in. long, white; pedicels 3–4 lines long; perianth greenish, 12–15 lines long; filaments filiform; berries orange. Cape of Good Hope. *D. latifolia*, Regel, is a horticultural variety, with lvs. 3–3½ in. wide. G.C. III. 20:305 (var. *latifolia*). B.M. 4279 (as *Cordylina Rumphii*.) Var. *variegata*, Hort. Variegated foliage.

4. *frāgrans*, Ker-Gawl. (*Āletris frāgrans*, Linn. *Sanseviēria frāgrans*, Jacq.). Arborescent (20 ft. high or more), sometimes branched; lvs. (1½–3 ft. x 2½–4 in.) sessile, oblanceolate, lax and spreading or recurved, flaccid, green and shining, acute, indistinctly costate:

1345. *Dracena fragrans* var. *Lindenii*.

bracts minute, scarious, deltoid; pedicels 1–1½ lines long; fls. glomerate; perianth 6–8 lines long, yellow; berry orange-red. Guinea. B.M. 1081. A.G. 18:389. F.R. 4:189. Gn. M. 8:270. G.W. 12:232. G. 2:286.—Much used for greenhouse and table decoration. *D. Knérkii*, Hort. Form with glossy light green, less pendulous lvs. *D. Rothiāna*, Hort. A garden form. I.H. 43, p. 97. R.H. 1877, p. 68. *D. Victōria*, Hort. A garden form. Gn. 63, p. 77. Var. *Lindenii*, Hort. (*D. Lindenii*, Hort.). Fig. 1345. Lvs. recurved, traversed from base to apex by creamy white bands. Very decorative. I.H. 27:384. F.R. 4:191. G.W. 14:321. A.F. 35:1241. G.C. III. 30:176. Var. *Massangeāna*, Hort. (*D. Massangeāna*, Hort.). A broad yellow stripe along the center of the lf. throughout its entire length. F.R. 4:193.

5. *deremēnsis*, Engler. Plant 9–15 ft. high, branched; lvs. 1½ ft. long, 2 in. wide, narrowed into a broad petiole-like base; infl. large; fls. on pedicels 1½–2 lines long; perianth 7–8 lines long, with tube 4 lines long, dark red without, white within, unpleasant scented. Afr. G.C. III. 50:23. G.M. 54:523. G.W. 11:505 (all as var. *Warneckii*).

6. *Goldiēana*, Hort. Plate XXXVII. Trunk simple, slender; lvs. distant, spreading, thick-oblong (7–8 in. x 4–5 in.), cuspidately pointed, base broadly rounded or cordate, glossy green, conspicuously white-spotted and banded, young lvs. often tinged with red; petioles erect (2–3 in. long), deeply grooved; fls. unknown. W. Trop. Afr. B.M. 6630. R.H. 1878, p. 15. I.H. 25:300; 42, p. 257. G.C. II. 17:49. G.Z. 22:1. G. 2:271; 14:239. G.W. 12:235.—A fine foliage plant.

7. *Sanderiāna*, Hort. (*D. thaloides* var. *variegata*, Hort.?). Slender; lvs. distant, alternate, spreading or recurved (7–10 x ½–1½ in.), narrowly lanceolate, acuminate, on rather broad petioles (1–3 in. long), glossy-green, broadly margined with white. Congo. A.F. 8:1281; 11:235. I.H. 40:175. G.C. III. 13:445. G.W. 14:322. Gn.W. 14:617. G. 23:533. G.L. 16:235.—Intro. in 1893.

8. *Godseffiāna*, Hort. Woody, but very slender, rather diffuse; lvs. at many nodes small, erect, scale-like and lanceolate, the others opposite or in whorls of 3, oblong or obovate, spreading, cuspidate, sessile (3–4 x 1½–2 in.), firm, green, with copious white spots; raceme short-peduncled; bracts small; fr. globular, greenish yellow or red, nearly 1 in. diam. Congo. G.C. III. 21:347. Gn. 50, p. 276; 51:298, and p. 299. A.F. 13:1340. F.E. 10, supp. 2:12. Gng. 6:294. G. 19:388.—Fine for decorative purposes.

The following are apparently not in the American trade: *D. americanā*, Donnell Smith. Twenty to 40 ft. high; lvs. linear-sword-shaped, 8–15 in. long, green; fls. white, small, in dense panicles. Allied to *D. Draco*. Cent. Amer. S.T.S. 1:207. New.—*D. arborea*, Link. Lvs. green, sword-shaped, dense, sessile. Gt. 46:1438; and p. 226. G.W. 8:260; 12:232.—*D. Brodmfieldii*, Hort. Lvs. spreading or recurved, strap-shaped, undulate, sessile, deep green bordered with broad white margins. J.H. III. 33:541. G.C. III. 20:667; 23:249; 33:249 (var.) G. 27:597. G.W. 13:4.—Botanical status obscure.—*D. concinna*, Kunth. Lvs. oblanceolate, green, purple on the margin, green-petioled.—*D. cylindrica*, Hook. Lvs. linear-lanceolate, or obovate-lanceolate, bright green, spreading. B.M. 5846.—*D. Eeckhantii*, Hort. F.R. 4:46. Gn.W. 16:697.—*D. elliptica*, Thunb. Lvs. spreading, petioled, thickish, elliptic-lanceolate, glossy, acute, longitudinally striate. B.M. 4787. G.C. II. 17:261 (var. *maculata*).—*D. ensifolia*, Hort. Amer.—*Dianella ensifolia*.—*D. kewensis*, Hort. Lvs. dark green, broadly oblong-lanceolate; petiole red, half as long as the blade. New Caledonia. New. May be a form of *C. terminalis*. G.C. III. 33:265. F.E. 15:619.—*D. marginata*, Lam. Lvs. sword-shaped, dense, spreading, green, margined and veined with red. G.W. 12:235.—*D. marmorata*, Hort. B.M. 7078.—*D. phrynoides*, Hook. Lvs. petioled, mostly oval, acuminate, coriaceous, spotted with yellowish white, pale beneath. B.M. 5352.—*D. reflexa*, Lam. Lvs. lanceolate or sword-shaped, acute, contracted into a petiole.—*D. Saposchnikovi*, Regel. Lvs. sword-shaped, crowded, green. Gt. 705.—*D. Smithii*, Baker. Lvs. large, narrowly sword-shaped, crowded, bright green. B.M. 6169.

Some trade names, the botanical status of which is in doubt, are the following: *alba-marginata*, *albanensis*, *Alexandria*, *angustifolia*, *angustata*, *argenteo-striata*, *DeSmetiana*, *edmontoniensis*, *elefantissima*, *Elzabethia*, *Frederica*, *Hendersonii*, *imperator*, *Jamesii*, *Jansesii*, *Lacourtii*, *Mayi*, *Mandana*, *Offeri*, *perelyares*, *recurva*, *Salmonia*, *Shepherdii*, *spectabilis*. *D. nova-caledonica* is probably *Cordylina neocaledonica*, Lindl., with bronze lvs.

K. M. WIEGAND.

**DRACOCÉPHALUM** (Greek, *dragon's head*, from the shape of the corolla). *Labiātæ*. Hardy herbaceous annual and perennial plants of easy culture and of minor importance.

Allied to *Nepeta*, differing in having the calyx mostly straight rather than curved and unequally toothed: mostly erect herbs, with opposite entire, toothed or deeply cut lvs., the upper ones passing into bracts; fls. in many-fld. verticils which are axillary or terminal, blue or purple or rarely white; calyx tubular, about 15-nerved; corolla, upper lip somewhat notched and arched, the lower one 3-cleft and the middle part notched or 2-cleft; stamens 4, didynamous, the 2

anther-cells divaricate.—Forty species in Eu. and Asia and very sparingly in N. Amer.

Sandy loam, moderately rich, and a rather moist, partially shaded situation will suit these plants best. In a sunny dry border they are never very showy; the flowers are of short duration, and are seldom at their best except in very moist seasons. Propagation is by division or seeds. The species described below are erect-growing.

A. *Lvs. entire, not cut in any way.*

**Ruyschiàna**, Linn. (*Ruyschiàna spicàta*, Mill.). Perennial, 2 ft.: sts. slightly pubescent: lvs. linear-lanceolate, glabrous: bracts ovate-lanceolate, entire: whorls in somewhat interrupted spikes; fls. 1 in. long, purplish blue or purple; anthers villous. Siberia. Var. **japònicum**, Hort., has white fls. shaded with blue, and is a distinct improvement. G.C. II. 12:167.—According to Vilmorin, this species has been sold as *D. altaïense* (see *D. grandiflorum*).

AA. *Lvs. deeply 3-5-cleft.*

**austriacum**, Linn., has the habit of the above, and belongs to the same subgenus *Ruyschiàna*, but the lvs. are divided and more distinctly revolute at the margin. About 1-1½ ft. high: fls. blue, 1½ in. long and more: perennial. July, Aug. Eu., Caucasus.

AAA. *Lvs. cut only at the margin, mostly crenate.*

B. *Whorls crowded together into spikes or heads.*

**grandiflorum**, Linn. (*D. altaïense*, Laxm.). Perennial, about 1 ft. high: root-lvs. long-stalked, oblong, notches at base; st.-lvs. few, short-stalked, ovate, not notched at base, the uppermost still more rounded: whorls in spikes 2-3 in. long, the lowest whorl usually at some distance: fls. 2 in. long, blue. June, July. Siberia. B.M. 1009. P.M. 13:51.

**speciosum**, Benth. Allied to *D. grandiflorum*, but st. pubescent instead of pilose above: root-lvs. more broadly heart-shaped, and all lvs. pubescent beneath instead of nearly glabrous, and wrinkled: fls. purplish to deep purple. June, July. Himalayas. B.M. 6281.

BB. *Whorls distant, in long racemes.*

**Moldávica**, Linn. (*Moldávica punctàta*, Moench). Lvs. lanceolate, incise-crenate, the floral ones narrower and pectinate: fls. in few-fl. loose clusters; corolla 2 or 3 times as long as calyx, blue or white. European annual, 1-2 ft., sparingly run wild in N. Amer. Eu., N. Asia.

**Rèprechtii**, Regel. Perennial: dwarf or compact, 1-1½ ft.: lvs. ovate-lanceolate, incised and toothed: fls. rosy purple or lilac, about 1 in. long, in axillary clusters. Turkestan. Gt. 1018.

**nùtans**, Linn. Perennial, 1 ft.: lvs. ovate-crenate, the floral ones oblong-lanceolate and more nearly entire: fls. blue. May-July. N. Asia. Mn. 4:137. B.R. 841. Var. **alpina**, Hort., is advertised.

*D. canariense*=*Cedronella triphylla*.—*D. canescens*, Linn.=*Lallemantia*.—*D. virginianum*, Linn.=*Physostegia*.

WILHELM MILLER.

L. H. B.†

**DRACONTIUM** (derived from the Greek word for dragon). *Aracæ*. Greenhouse or hothouse plants, grown more for curiosity than for beauty.

Herbs with long-petioled lvs.: petioles verrucose; blades deeply 3-parted, these again parted: spathe oblong, convolute below; spadix short-stalked, short, cylindric, free, densely many-fl.; fls. perfect, with a perianth: fr. a 2-3-celled berry, each cell 1-seeded.—About a half-dozen species in Trop. Amer. Cult. as for *Amorphophallus*.

**ásperum**, Koch (*Amorphophallus nivòsus*, Lem.). Petioles up to 9 ft. long and over 1 in. thick, roughened toward base with small warts conjoined in series, marked with large livid green and brown spots; blades

up to 3 ft. broad, 3-parted, the divisions bipinnate, the ultimate segms. oblong to lanceolate: peduncles 4 in. or more long; spathe up to 10 in. long; spadix 1½-2 in. long. Brazil. I.H. 13, p. 14; 12:424.

GEORGE V. NASH.

**DRACUNCULUS** (Latin, a little dragon). *Aracæ*. Odd tuberous plants sometimes grown under glass.

This plant has interesting dragon-fingered lvs. and a terrifying odor when in flower. Its tubers are sold by bulb dealers under the name of *Arum Dracunculus*. The monographer of this order (Engler, in DC. Mon.

1346. *Dracunculus vulgaris*.

Phan., vol. 2, 1879) puts this plant into the genus *Dracunculus* because the ovules are attached to the base of the ovary, while in *Arum* they are attached to the side. The lvs. of the true arums are always arrow-shaped, while in *Dracunculus* they are sometimes cut into finger-like lobes. There are only 2 species. The common one is an entertaining, not to say exciting, plant. It is well worth growing for the experience, though its stench is not quite so bad as that of a *heliconia*, sold as *Arum crinitum*, which makes any house unbearable in which it flowers. Nearly all arums are ill-smelling. For cult., see *Arum*.

**vulgaris**, Schott. Fig. 1346. Sheath of lvs. livid, spotted; stalks green; blades with 10 fingers projecting from a bow-shaped base: tube of spathe streaked with purple except at the bottom; spathe purple all over and much darker along the wavy border. Medit. regions. G.C. III. 47:198.

WILHELM MILLER.

**DRAGON PLANTS.** The dragon arum, dragon root or green dragon, is the native *Arisæma Dracontium*. The dragon plant of Europe is *Dracunculus vulgaris*. The dragon's head is not an aroid, but a *Dracocephalum*, a genus of mints. False dragon's head is *Physostegia*. The dragon's blood of commerce is a dark red, astringent, resinous secretion of the fruits of a palm,

*Dæmonorops Draco*. Other kinds of dragon's blood are produced by *Dracæna Draco* and *Ecastophyllum monetaria* (now referred to *Dalbergia*). "Sticks," "reeds," "tears" and "lumps" of dragon's blood are known to commerce. The resin is used in coloring varnishes, dyeing horn in imitation of tortoise shell, and in the composition of tooth-powders and various tinctures. The dragon tree is *Dracæna Draco*.

**DRAINAGE.** Underground or sub-drains serve to relieve the land of free water, which is harmful to most plants if left to stagnate in the surface soil or subsoil. They serve not only to dry the land in early spring, but indirectly to warm it, for if the water is removed the sun's heat warms the soil instead of cooling it by evaporating the surplus water. Tenacious lands devoted to gardening and small-fruits are made more productive, warmer and earlier by sub-drainage. Drains promote nitrification, assist in liberating mineral plant-food and cheapen tillage. They serve not only to remove deleterious stagnant water, but they promote aëration as well, and this hastens beneficial chemical changes in the soil. Drainage promotes the vigor, healthfulness and fruitfulness of plants. Tenacious soils are made more friable by drains, thereby giving

1347. Diagrams to explain the effect of lowering the water-table by means of under-drainage. On the undrained soil, the roots do not penetrate deep; and when droughts come, the plants suffer.

easier access to plant roots, while the percolation through the soil of rainwater, which carries some plant-food, is hastened. Rain-water in the spring is warmer than the soil; in midsummer it is cooler than the soil; therefore, percolation of rain-water warms the soil in the spring and cools it in extremely hot weather. Drains serve not only to relieve land of free water, but they impart to it power to hold additional available moisture, which materially benefits plants during droughts.

Drainage is of two kinds, surface and sub-drainage. On land on which large outlays of money are to be expended, as in horticultural plantations, it is of the utmost importance that the soil be freed to considerable depths from stagnant water. Trees, many shrubs, and even some garden crops send their roots deeper into the subsoil than most of the cereals, hence they require a greater depth of drained feeding-ground. In horticulture the planting may often precede the harvest by five to ten years, while with many farm crops the harvest follows the planting in a few months. If the grain-raiser loses one crop, an annual, by planting on wet land, the loss is not great, but if the orchardist loses fifteen to twenty years of labor by planting on undrained lands, before the mistake is discovered, the losses are serious. Some lands require little more than to be relieved from surplus surface water in early spring. This may be accomplished by forming ridges and open

furrows as far asunder as the rows of trees are to be placed. But it is only rarely that surface drainage fully prevents serious damage from surplus moisture. Surface drainage may be considered a cheap way of temporarily alleviating undesirable conditions. It does not always eradicate them. Fig. 1347 illustrates how sub-drainage lowers the water-table (or the area of standing water), and thereby ameliorates the soil.

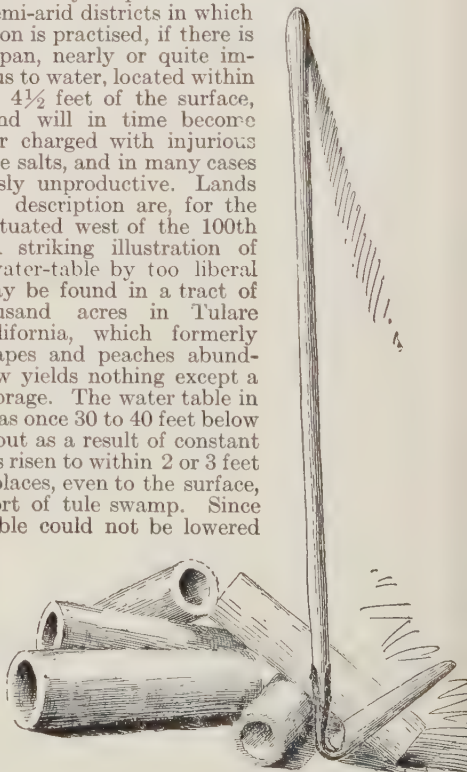

Sub-drainage consists in placing conduits of tile or other material in the ground at depths varying from 2½ to 4 feet, and at such distances apart as

1348. Old-fashioned drain-tile.

will serve to relieve the subsoil of deleterious stagnant water. When suitable stones are at hand, they are sometimes used instead of tile for forming drainage conduits. If such use is made of them, the drains should be somewhat deeper than tile drains, since the stones which form the drain occupy nearly a foot of the depth of the ditch and are more likely to become obstructed, especially if placed near the surface, than are tile drains. The throats or openings of stone drains are irregular in size, while those of tile drains are smooth and uniform in size, and are, therefore, most desirable. Years ago, various flat-bottomed tiles (Fig. 1348) were employed, but the style in general use at present is the cylindrical unglazed tile shown in Fig. 1349. They should be hard-burned. Because of the low cost of cement, tiles made of sand and hydraulic cement have recently come into use; they require no burning, are stronger than tiles made of clay and are just as efficient, except in alkali and where frost penetrates very deep.

In semi-arid districts in which irrigation is practised, if there is a hardpan, nearly or quite impervious to water, located within 3½ to 4½ feet of the surface, the land will in time become sour or charged with injurious alkaline salts, and in many cases ruinously unproductive. Lands of this description are, for the most part, situated west of the 100th meridian. A striking illustration of raising the water-table by too liberal irrigation may be found in a tract of several thousand acres in Tulare County, California, which formerly produced grapes and peaches abundantly but now yields nothing except a little hardy forage. The water table in this region was once 30 to 40 feet below the surface, but as a result of constant irrigation has risen to within 2 or 3 feet and, in low places, even to the surface, forming a sort of tule swamp. Since the water-table could not be lowered enough to restore the land by under-drainage, for lack of an outlet within reasonable distance, it is probable that the only way to reclaim it

1349. Common cylindrical drain-tile; and a scoop for preparing the bed for the tile.

would be to sink a well and pump the surplus water into a surface ditch. Irrigation with pure water would then sweeten the soil and render it again productive; and the whole process of restoration need not be excessively expensive.

If the hardpan is less than 2 feet in thickness, the land may be improved greatly for orchard and vineyard purposes by the use of dynamite. Blasting should be deep enough to allow the surplus water to escape into the porous earth or gravelly soil beneath the hardpan. On the Pacific coast this method of draining orchard and vineyard land has been quite successful. In any case, unless the soil has good natural sub-drainage, it is both wise and economical to blast out holes for trees and vines; for the cost of digging holes, if they are as large and deep as they should be, is lessened by an amount almost equal to the cost of blasting.

Recently, powerful tractors have solved, to some extent, the problem of drainage in many cases by making deep plowing possible before planting and during the first few years of subsequent tillage of the orchard or vineyard. This machine with the tillage implement turns easily at the ends of the field within the space allowed for turning a span of horses and a plow; it can pass under limbs where a 14-hand horse (56-inch) can

1350. Improper method of draining a field.

pass, and as close to the plants as a span of horses can. It furnishes also power and locomotion for spraying and for opening trenches to a considerable depth (18 to 44 inches) for the reception of drain-tile.

In some regions, drains are placed 200 to 300 feet apart, and serve their purpose well. In others they should not be placed farther apart than 20 to 30 feet. Wherever the subsoil is composed of tenacious fine clay, through which the water moves upward or downward with difficulty, the narrower intervals are necessary. In some instances the surplus water in the subsoil is under pressure by reason of water which finds its way into it from higher levels, and if this is not removed, the water has a constant tendency to rise to the surface. In many such cases drains placed at wide intervals may serve to relieve the pressure and drain the land. Since sub-drains are designed to be permanent, are expensive to construct and difficult to repair, the principles of drainage should be well understood, and the work should be undertaken only after a most careful inspection of the land and after the fundamental principles of the subject have been mastered.

Mains and sub-mains should be avoided so far as possible, since they greatly increase cost, tend to become obstructed, and are often unnecessary. The three long mains in Fig 1350 are not drains, strictly speaking, since the land may be as fully drained without them, as shown in Fig. 1351; therefore, they serve

only to conduct the water of the drains proper. Tiles of 3 to 4 and 5 inches diameter should be used when the drains are infrequent and the flow of water considerable. Smaller ones, 2 to 3 inches in diameter, will suffice when the intervals between the drains are narrow.

1351. Best method of draining a field.

Drains should have as uniform a fall as possible, and no abrupt lateral curves or sharp angles should occur as are seen in many places in Fig. 1350. If the drain has a rapid fall in its upper reaches, as is often the case, and but slight fall in the lower, a silt basin should be constructed at the point at which the rapid changes into the slight fall, if obstructing silt is present. All drains which may be necessary should be placed before the planting occurs. Orchard lands may be drained in the spring, fallowed in the summer, and planted in the fall or the following spring. Drains placed at frequent intervals because of the tenacity of the soil should be comparatively shallow, for if placed deep or at wide intervals, the water will be too long reaching them. If drains are placed at wide intervals they should be at least  $3\frac{1}{2}$  feet deep to be most efficient. If the parallel system is adopted (Fig. 1351), there may be more outlets to construct and maintain than is desirable; if so, the system might be modified by constructing a sub-main, one side of which will serve also as a drain, and but one outlet will be required (Fig. 1352). Drains through which water runs for the greater part of the year are likely to become obstructed by roots, if water-loving trees, such as the willow, soft maple, and elm, are

1352. Showing how the drains may be gathered into one when there is only one place at which an outlet can be secured.

allowed to grow near them. If floating silt is present, the joints of the tiles should be protected for two-thirds of their upper circumferences by a narrow strip of tarred building paper (Fig. 1353), or collars should be used. Stone drains should receive a liberal covering of straw or some similar material before they are filled.

I. P. ROBERTS

### Drainage for landscape work.

The value of a thorough knowledge of the possibilities of drainage in landscape work has been overlooked until recent years as a definite field entirely apart from general drainage for agricultural purposes.

Drainage under the headings of this article is installed with the following objects in view:

1. Maintaining well-drained areas for firm lawn surfaces.
2. Maintaining well-drained and firm surface conditions for recreation areas.

1353. Covering a joint.

3. Draining of surface water and ground water from roads.
4. Draining foundations for walks.
5. Preserving the normal soil conditions for newly planted trees.
6. Draining swamp and marsh areas to prevent breeding of mosquitos.

#### 1. Drainage for lawns.

The secret of a perfect lawn is attributed to drainage conditions which provide a well-drained subsoil and a firm surface that may be readily freed from any excess water during heavy rains. The installation of drainage for this purpose is required only in the more compact soils that do not drain naturally. Sandy soils seldom require artificial drainage unless immediately underlaid with a stratum of impervious clay. On any lawn the topography of which does not permit the ready surface run-off and the subsoil of which is compact clay, the necessity of installing sub-surface drainage is strongest.

A drainage system for providing ideal soil conditions for perfect lawns must be installed carefully. Four-inch tile, is often used in the lateral systems while either 6-inch vitrified pipe, or the No. 2 quality of 6-inch round tile, is used for the main lines. All drains should be laid on an even grade of not less than  $\frac{1}{8}$  of an inch fall to each linear foot of drain, and preferably not less than  $\frac{1}{4}$  of an inch fall for each foot of drain. If perfect drainage is desired, the distance apart of these drains should not exceed 20 feet. In accordance with the general laws of drainage, tile should be laid at a more shallow depth in the heavy soils than in the lighter soils, and should be spaced at closer intervals than 20 feet, this space varying largely with the desire to free the lawn immediately of any excess surface water.

In all tile drainage whether for lawns or other purposes, a space of approximately  $\frac{1}{8}$  inch should be allowed between the ends of the pipes. The covering of tar paper and cinders should be placed over each joint as shown in Fig. 1353. The tile should be placed on a firm bottom of clay or other natural soil, and surrounded on all sides, and covered to a depth of not less than 6 inches with cinders, crushed stone, or washed

gravel (Fig. 1354). In very heavy clay, the trench excavated for the tile should be filled with cinders, crushed stone or gravel to a line separating the looser top soil from the clay subsoil (Fig. 1355). In heavy soil and for perfect lawn drainage, the lines of tile ought not to be laid deeper than  $2\frac{1}{2}$  feet and the cinder fill should not be less than 15 inches in depth. In the lighter sandy loam soils, the tile may be laid to a depth of 3 to  $3\frac{1}{2}$  feet.

It is often found necessary when lawns are constructed on sandy soil to prevent excessive drainage, rather than to encourage drainage conditions. In these extreme sandy soils, the surface water seeps away so readily that the lawns become exceedingly dry during the warm and dry months. To prevent this condition a layer of clay 4 inches deep should be distributed over the sandy sub-grade prepared for the lawn, at a depth varying between 10 and 18 inches below the proposed finished surface of the lawn. This clay is thoroughly compacted and serves as a partial barrier against abnormal seepage which would otherwise occur, and thereby retains the moisture necessary for the capillary attraction to feed the roots of the lawn grasses.

#### 2. Recreation areas.

Areas naturally falling under this heading are tennis-courts (clay and turf), bowling-greens, clock-golf areas, and croquet-lawns. All of these require a more careful study of drainage conditions than is

1354. The filling of a drain.

1355. Applying good top soil.

given to the average lawn. It is essential that such areas be so completely drained that the surface condition is always firm, even after the average continuous heavy rains.

**Tennis-courts.**—These areas require the most careful study of drainage conditions. The average tennis-court requires two types of drainage,—surface and sub-surface. Surface drainage is cared for in two ways, (1) either by giving the court a gradual slope to one end, or (2) as shown in Fig. 1356, where the surface of the court is sloped from either end toward the middle line. This method, shown in Fig. 1357, gives probably the most satisfactory results, because, in this way, if surface conditions at the middle of the court are correct, the surface water is cared for most readily and with the shortest possible run-off. This drain across the middle of the court may be either an open concrete drain with a plank laid over the top and flush with the surface of the court, or a blind drain filled with a

1356. Draining a tennis-court.

coarser crushed stone and fine crushed stone, over which is spread a thin layer of washed sand. The bottom of the drain ought to be approximately 6 inches lower, at the point where the outlet to the sub-drain is located, than the elevation at the extreme high points of the drain. The method of establishing these grades varies largely with the requirements of this particular problem. The water, as it reaches the low point in the drain, is conducted at once into the main 6-inch drain, which also takes ground-water from the underground system of drains. When the court is so constructed that one end is lower than the other, in order to assist surface-drainage conditions the courts should be level from side to side. Fig. 1357 shows the general distribution of the system of tile to care for the sub-surface water in tennis-court construction. This would apply equally well to the construction of other recreation areas, including clock-golf-greens, bowling-greens and croquet-lawns. In the construction of all tennis-courts, the trenches excavated for the tile should be filled with cinders or an equally porous material to a height not less than 6 inches below the proposed finished grade of the court.

*Clock-golf-greens, bowling-greens, and croquet-lawns.*—A thorough distribution of tile drains installed as outlined below, should meet all the requirements commonly imposed from the drainage standpoint upon the construction of these recreation areas. Lines of 4-inch tile should be placed, at intervals of not more than 10 feet. For the most thorough and ideal drainage of these areas, provided the cost is not prohibitive, the construction would be as follows: A neat sub-grade should be made at a depth not exceeding 15 to 18 inches below the proposed finished surface of the recreation area. The necessary lines of tile should be laid in trenches at a depth varying between 2 and 2½ feet below the finished grade, these trenches to be filled with cinders, crushed stone or gravel (Fig. 1355). On this sub-grade, thus completed, the entire recreation area should be filled to a point approximately 6 inches below the proposed finished grade, with cinders, or some equally porous material. On this finished surface, the remaining 6

middle of the road is used in soils in which the ground-water level is abnormally high. Such drains should range in depth from 2 to 3½ feet below the finished surface of the road, and the trenches should be filled with a porous material and not with the natural soil. The method of installing drainage under the sides of the

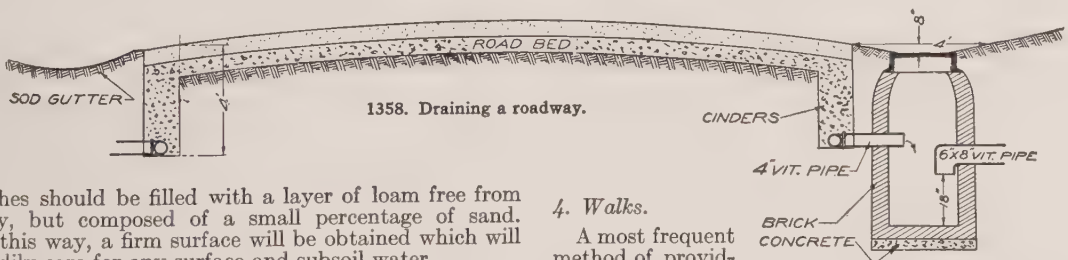

1357. Draining a tennis-court.

road, as shown in Fig. 1358 is used in heavy clay soils, and serves to keep the foundation of the road on well-drained soil. These drains are installed at a depth varying from 2 to 3 feet in trenches filled with cinders or equally porous material.

Turf pleasure roads, so frequently constructed on private estates, should be thoroughly drained with a line of tile placed under the middle of the road, unless the road is constructed on a heavy foundation of field-stone or gravel which forms a natural drain path for surface-water and soil-water.

In providing drainage along the sides of roads constructed on clay soils through virgin woods, it is sometimes necessary to carry these drainage lines a considerable distance through the woods to suitable outlet points. The joints of all such lines of drainage should be cemented, otherwise the artificial conditions produced by the increased drainage will work serious injury to many large trees growing on either side. In general it is very unsafe to install drainage lines through virgin woods, without this precaution. Roads constructed through such woods would better be drained by laying a line of tile under the middle of the road as shown in Fig. 1359.

1358. Draining a roadway.

inches should be filled with a layer of loam free from clay, but composed of a small percentage of sand. In this way, a firm surface will be obtained which will readily care for any surface and subsoil water.

### 3. Roads.

The secret of a perfect road surface lies (1) in the proper crown of the road, and (2) in the adequate drainage of the subsoil or foundation. The first provision cares for the surface water, and the second provision eliminates any surplus ground-water.

On all private estates on which roads are constructed on heavy clay soils and not on grades greater than 4 per cent, the secret of success depends upon drainage installed in either of the two ways shown in Fig. 1358 or Fig. 1359. Installing a line of drains under the

### 4. Walks.

A most frequent method of providing drainage for walks is that shown in Fig. 1359. A line of 4-inch tile is laid at a depth varying between 18 inches and 30 inches below the finished grade of the walk and following the middle line of the walk. The trench for the tile is filled with a porous material to a height even with the bottom of the cinders used for the foundation of the walk, or laid as shown in Fig. 1359.

### 5. Newly planted trees.

All trees planted in clay soil require drainage. If the pockets in which such trees are planted are not

thoroughly drained, the area excavated and re-filled with soil when the trees are planted becomes a pocket for ground-water. This pocket or reservoir collects the water, which, if not carried off by means of drains, will very likely cause the death of the trees. All large trees, especially those which do not grow best with their roots in the water, must be provided with drainage. The common method of drainage is to install a line of 4-inch tile leading from the bottom of the excavated hole to a main line of tile which may have been installed for other drainage purposes, or to the nearest outlet if no such line exists.

#### 6. Drainage to prevent mosquito-breeding.

It is a frequent practice, especially on large estates, to install open ditches from 50 to 100 feet apart in swamps and in salt marshes, in order to provide a means for draining such areas, and thus preventing the presence of stagnant water, which is conducive to the breeding of mosquitos. These trenches are excavated at depths varying from 2 to 3½ feet. The more frequent the trenches, the shallower they may be made and still provide adequate drainage.

The foregoing article pertains only to the particular phases of drainage especially to be considered in connection with landscape work. For additional information on the general details concerned with drainage, refer to the main article upon drainage, p. 1072.

A. D. TAYLOR.

1360. Detail of drain connections. (See Fig. 1356.)

#### Drainage and watering for newly transplanted trees.

Drainage is an essential in all retentive soils and is a safeguard even on sandy gravelly subsoils against overwatering. Drainage is likely to be vetoed on the score of expense or on the excuse that the subsoil is gravelly; whereas, there are only gravel stones in hardpan which holds water. A drain made by filling a pit with stones is frequently inadequate as it fills with water, which backs up into the hole, saturates the soil around the roots and rots them. Rotting of only a part of the roots may injure the tree more than the cutting off of that amount of roots.

The soil in which to plant should be open, porous and aerated. Soil which has been piled up as in grading operations is likely to be sour from the decay of the sod and from the packing by teams and scraper. Muck from ponds which has been piled and mixed with lime for a year may still be sour. Clay soil packed by the water and packing-sticks may remain too compact and not aerated enough, may be too much saturated with water and, therefore, rot the roots. Manure should not be mixed in the soil around the roots on account of the danger of souring and rotting the roots. This rotting is determined by digging down to the

roots and finding them of blue-black color with a sour smell. Sometimes this decay has not reached through the bark of the roots and other times it has penetrated the bark and turned the cambium blue-black. Sour soil is likely to be of bluish or greenish color rather than chocolate-brown, and have a sour smell like that under-

neath a manure heap. The smell is most readily detected by breaking open a lump of soil. In digging into sour soil and soil that is over-saturated, the spade makes a peculiar sucking noise as in digging in a bog. If at the time of examination the soil is already become sour,

it is best to take out this sour soil and put in fresh soil covering the roots only 4 inches. The ball of earth in the center will not be so liable to get sour because it has not been disturbed. As brought out by Stringfellow in the "New Horticulture," soil that is dug over will take in water and become saturated; whereas, soil that has not been disturbed will retain air in the soil-spaces even if submerged. The ball of earth is also prevented from becoming saturated by the undisturbed feeding-roots which absorb the moisture.

Watering cannot be by rule, but must depend on examination of both ball of earth in the center and the outer roots. The difficulty will be to keep the ball of earth sufficiently damp on account of the rapid withdrawing of moisture by the roots. The danger will be that the soil outside the ball of earth will take up the water too rapidly, remain saturated several days and rot the roots. Examination is best done by shovel and fork, digging down 1½ feet both in the ball and outside. An easier way is to bore into the soil with an auger. It will usually be found that the central ball of earth is dry and dusty in the summer even if the surface and outer soil is damp. The growth of weeds and grass will indicate the same. A good way to water is to make a basin around the width of the ball of earth, fill it with water 6 inches deep, make crowbar holes into the ball for it to soak in. Many mistakes are made in overwatering—letting the hose run all night or watering every day, thereby rotting the roots.

Mulching is frequently neglected, the tree starving for lack of humus. A close-

1361. Setting a newly transplanted large tree.

cut lawn around a newly planted tree may be the ideal of neatness, but it means starvation and thirst for the tree and is the principal cause of slow growth over several years, making new, bare and ugly landscapes. The mulch should extend as wide as the roots and be from 3 to 6 inches deep, of strawy manure, leaves, grass, salt hay or similar organic matter. Too much manure may sour the soil and rot the roots, if it lies heavy and compact and keeps out the air. Light strawy manure is better. If the mulch blows about and is untidy, it may be kept in position by wire netting, earth, or the planting of small shrubs.

HENRY HICKS.

**DRĪMIA** (name refers to the acidity of the roots). *Liliaceæ*. Bulbous S. African and Trop. African plants of the Scilla tribe, with gamophyllous perianth and a campanulate tube, the segms. linear-oblong and reflexing: stamens 6, shorter than the segms., and inserted at the throat of the perianth-tube; ovary sessile, ovoid, 3-celled, becoming a loculicidally 3-valved membranous caps.: lvs. either broad and rather fleshy or narrow and rigid, often appearing at a different season from the bloom: fls. on a naked peduncle or scape, in a simple raceme.—About 30 species, none of which appears to be regularly in cult. *D. oligosperma*, C. H. Wright. Probably from S. Afr., and very recently described: fl.-clusters over 6 ft. high, much branched, the beautiful white fls. with 3 green nerves on the oblanceolate spreading petals opening late in the afternoon: bulb elliptic, 6 in. long: lvs. 12–14, rosulate, 1½ ft. long, linear-acuminate, glabrous. Likely to come into commercial cult.

**DRĪMYS** (from a Greek word, used in allusion to the sharp or acrid taste of the bark). *Magnoliaceæ*. About 10 evergreen trees or shrubs, allied to *Illicium*, distributed from Mex. to the Straits of Magellan, and in Austral., New Zeal., and islands. Glabrous and aromatic plants with pellucid-punctate lvs., and polygamous diclinous or perfect fls. on 1- to many-fl'd. peduncles, white, yellowish or rose-colored and showy; sepals 2–4; petals 6–∞, in 2 or more series; stamens ∞, on thickened filaments; ovaries usually 2–∞, with sessile stigma and many seeds. *D. Winteri*, Forst. (*Wintera aromatica*, Murr.), is a S. American small tree (to 50 ft.), with milk-white fls. 1 in. or more across, jasmine-scented; petals 8–12, pale cream-yellow: lvs. alternate, evergreen, elliptical or lanceolate, coriaceous, somewhat acuminate, entire, glabrous, very aromatic: branches with reddish bark: umbels (3–9-fl'd.) often nearly equaling the lvs.: scarcely known either as a glasshouse subject or for outdoor cult. in warm countries. B.M. 4800.

L. H. B.

**DRÓSERA** (Greek *droseros*, dewy, from the dew-like excretions on the tips of the leaf-hairs). *Droseraceæ*. A group of carnivorous plants popularly known as the SUNDEWS or DEW-PLANTS.

The sts. usually short, slender or compressed, rarely elongate and upright in such types as *D. peltata*: lvs. varying from linear through lanceolate to circular, often arranged in a rosette, and beset over their upper surfaces with fine often irritable hairs, that excrete a clear neutral viscid fluid which entangles and catches insect prey; the hairs then bend inward toward the lf.-center, the fluid becomes acid and also excretes a proteinaceous ferment by which the animal tissues are digested, the dissolved products being then absorbed for the plant's nutrition: fl.-scapes slender, ending in curved scorpioid cymes of blooms, ¼–1½ in. across, and varying from white through pink to scarlet or crimson; sepals, petals and stamens 5 each, while the carpels vary from 5–3, are syncarpous with parietal placentation, and bear as many style-arms or lobes: fr. a caps.—About 90 species scattered over the world, though most abundantly in Austral. Monograph by Diels in Engler's *Pflanzenreich*, hft. 26. The species usually grow in moist muddy soil, at times almost floating in water, as in the common N. J. species, *D. intermedia*. Some Australian kinds form tubers, and can then survive through dry periods. The lvs. in our native species wither in autumn, and a small winter bud-rosette is formed, which unfolds its lvs. in the succeeding spring.

The native and exotic species all grow well if treated as greenhouse plants, and grown in fine muddy loam topped by a little sphagnum. They should also be

kept constantly moist in their root extremities, and exposed to bright light. The following native and exotic species are now often grown in collections. They can be propagated by seeds, by division of the shoots, or by cutting the slender rhizomes into short lengths of ½–1 in. The last, when placed in moist soil, root and form buds in two to three weeks.

*binata*, Labill. (*D. dichotoma*, B. & S.). Sts. short: lvs. long-stalked, 6–16 in. high, once- to twice-forked into long-linear reddish green segms. that are covered with viscid hairs: scape branched above; fls. white, ½–¾ in. across; fls. June, July. Austral. and N. Zeal. B.M. 3082.—Intro. in 1823. Easily grown and prop. by division of the crowns.

*capensis*, Linn. St. slightly elongate: lvs. in a terminal rosette, linear to spatulate, tapered into petiole, obtuse at apex: scapes 6–10 in. long with 5–20 secund purple fls.; fls. June, July. Afr., southwestern part of Cape Colony. B.M. 6583.—Intro. in 1875.

*filiiformis*, Raf. St. short, hair-covered: lvs. linear, erect, 6–8 in. long, greenish with abundant purple hairs: scape equal to or longer than above, 6–15-fl'd.; fls. rather crowded, unilateral; petals pink-purple, ¾ in. across; fls. June, July. Del. to Mass., along sandy coastal places. B.M. 3540. Torrey, Fl. N. York, 82: t. 10.

*intermedia*, Hayne. Rhizome slender, 1–4 in. long: lvs. 1½–2½ in. long, long-petioled, spatulate, red with glandular hairs: scape 6–12-fl'd.; petals white; fls. April (Fla.) to August (New Bruns.). E. N. Amer., Cuba, and Eu.—Forms wild hybrids at times with other species.

*peltata*, Smith. St. 6–10 in., bulbous below, slender elongate above ground, with scattered peltate glandular lvs., and terminating in delicate 6–10-fl'd. stalks: petals white to pink. From India through China, Japan and the Philippines to Austral. G.C.H. 19: 436.—A pretty, delicate and striking species now not uncommon in cult.

1362. *Drosera rotundifolia*. (×½)

*rotundifolia*, Linn. Fig. 1362. St. short, slender: lvs. ¾–2 in., with elongate non-glandular petiole and circular red-glandular blade: scape slender, 5–12-fl'd.; petals white, expanding in bright sunshine; fls. May (Carolinas) to Sept. (Newfoundland).—A classic plant, owing to Darwin's studies in "Insectivorous Plants."

*Tracyi*, Macfarlane. Habit of *D. filiformis*. Lvs. 12–16 in., pale green with light green glandular hairs: scape 15–24 in.; fls. purple, ¾ in. across. Abundant over the coastal area of the Gulf states from mid-Fla. to La. Fl. April, May.—One of the largest species of the genus. J. M. MACFARLANE.

**DROSOPHYLLUM** (*dew-leaved*). One of the 6 genera of the *Droseraceæ*, comprising a single species in S. Spain, Portugal and Morocco, sometimes seen in collections of insectivorous plants, and for the interesting morphology, the lvs. being revolute rather than involute as in the *droseras* and other plants. *D. lusitanicum*, Link, is a sub-shrubby little plant, the simple st. 2–6 in. high bearing at the top long-linear glandular insect-holding lvs.: fls. 1½ in. across, on an elevated stalk (1 ft. high), bright yellow, with 10–20 stamens, alternating in length, bearing short yellow anthers; petals

5, obovate, thin, twisted after anthesis; styles 5, filiform: fr. a narrow caps.,  $\frac{3}{4}$  in. long, 5-valved. B.M. 5796.—The glands of this interesting plant are purple, some stalked and some sessile, viscid, not motile. See Diels, in Engler's *Pflanzenreich*, hft. 26 (1906) for monographic treatment, where the *Droseraceae* is reduced to 4 genera, *Byblis* and *Roridula* being removed from the family; and Darwin studied it and described it in Chap. XV of "Insectivorous Plants." L. H. B.

**DRÛAS** (Greek, *wood-nymph*). *Rosaceae*. Dwarf hardy tufted evergreen somewhat shrubby plants, sometimes transferred to gardens.

Leaves alternate, petioled, simple, entire or crenate, tomentose: fls. large, white or yellow, borne singly on slender scapes; sepals 8–10, persistent; petals 8–10, obovate or oval; stamens many, with subulate filaments; pistils many, sessile, with a terminal style that persists and elongates on the achene. High northern or mountain plants, of N. Amer., Eu. and Asia, of which 4 species are recognized by Rydberg (N. Amer. Flora, xxii, part 5, 1913); allied to *Geum*.

The best known cult. species, *D. octopetala*, requires a well-drained porous soil, a sunny but not dry position. It is well to shade the foliage from bright sun during the winter months with evergreen branches to prevent the foliage from having a scorched appearance. A capital plant for the rockery. Propagated by cuttings, division, or by seed. (J. B. Keller.)

**octopétala**, Linn. Densely caespitose with a woody caudex or st.: lvs. rugose, elliptic, oval or oblong, deeply and regularly crenate, white-tomentose beneath: scapes 2–8 in. long; fls. white, the petals elliptic or obovate-elliptic, and the sepals linear or linear-lanceolate: seeds with a feathered awn 1 in. long. North temperate and arctic regions.

**Drummondii**, Rich. Caespitose perennial with decumbent caudex: lvs. elliptic or obovate, white-tomentose beneath but nearly or quite glabrous above, somewhat rugose, coarsely crenate: fls. yellow, the petals elliptic-spatulate or obovate and almost erect, the sepals ovate or ovate-lanceolate. Que. to Ore. and N. B.M. 2972.—A good rockery plant; 4 in., more or less.

*D. integrifolia*, Vahl. Fls. white; sepals linear or linear-lanceolate: lvs. lanceolate or lance-elliptic, the margins mostly revolute. High northern N. Amer.—*D. tomentosa*, Farr. Fls. yellow; sepals ovate or ovate-lanceolate: lvs. obovate or elliptic, coarsely crenate, tomentose on both surfaces. Canadian Rockies. L. H. B.

**DRYMOGLÓSSUM** (Greek, *wood and tongue*, of no direct significance). *Polypodiaceae*. Small ferns, 5 to 10 species, occurring wild in both tropics, with wide creeping rootstalks, and small, entire lvs.: sori resembling those of *Polypodium*. None is advertised in Amer. Three or 4 kinds are mentioned in horticultural literature abroad, but are not cult. here. L. M. UNDERWOOD.

**DRYMÒNIA** (from Greek for an oak wood: growing on trees). *Gesneriaceae*. Prostrate or climbing woody plants, sometimes grown under glass, but apparently not offered in this country. Fls. white or yellowish, mostly large, on short axillary usually solitary pedicels; calyx large, oblique, 5-parted; corolla-tube prominently ventricose, declinate, gibbous or saccate at base, the 5 lobes broad and spreading and only slightly unlike; stamens affixed in the base of the corolla, 4 perfect; disk-glands large at rear, small or wanting in front; style elongated: fr. fleshy, ovate, becoming 2-valved: lvs. opposite, thickish.—Some 15 species in Cent. and S. Amer., closely allied to *Episcia*. Warmhouse plants, requiring the treatment of other gesneriads. One species is offered abroad: *D. Turriallux*, Hanst., from Costa Rica: tall shrub: lvs. broadly ovate, blistered, metallic-colored: fls. large, white, pendulous, the lower lobe toothed, calyx red. *D. punctata*, Lindl. = *Episcia punctata*. L. H. B.

**DRYMOPHLEÛS** (Greek words meaning oak and smooth inner bark). *Palmaceae*, tribe *Areceae*. Spineless pinnate palms, with slender medium caudices.

Leaves terminal, equally pinnatisect, the segms. cuneate-oblong or linear, broadly oblique, submembranaceous, 3- to many-nerved, the margins recurved at the base; rachis scaly, 3-sided; sheath long: spadix with a short peduncle and slender branches; spathes 2 or many, the lower one 2-crested. This genus contains a tropical palm, with very distinct wedge-shaped lfts. and ornamental scarlet frs., borne every year. It flowers when only a few feet high, and is suitable for pot culture.—Species 12. Australasia and the Pacific isls.

The chances are that most of the plants now known to the American trade as *D. olivæformis* are really *D. appendiculata*. The true *D. olivæformis* is said to have been offered by a few dealers as *Ptychosperma Rumphii*. *D. appendiculata* was described and figured by William Watson, in Garden and Forest, mistakenly as *D. olivæformis*, as explained in B.M. 7202. He adds, "Like all the palms of this section of the border, *Drymophloeus* requires a tropical moist house with abundance of water at all times." G.C. II. 24:394. The plant figured was about fourteen years old, 3 feet high, with leaves about 3 feet long. The plant takes about six months to mature its fruits.

**appendiculatus**, Scheff. (*Arèca grácilis*, Giseke, not Roxbg. or Thouars). St. 6–10 ft.: lvs. terminal, 5–6 ft. long, arching; lfts. 14–20, wedge-shaped, raggedly cut, serrate: spadix from between the lvs., short-stalked, about a foot long; the yellow buds and white fls. make an attractive contrast at the flowering season (June). Moluccas, New Guinea. B.M. 7202. G.F. 4:331.—The *D. olivæformis* of most dealers not of Martius.

*D. Mooreanus*, Hort. "An erect-growing palm with grayish green lvs."—*D. olivæformis*, Mart., not the trade plant of that name, has narrower lfts. than the above, and the fr. half immersed in the greatly enlarged perianth.

JARED G. SMITH.  
N. TAYLOR.†

**DRYNÀRIA** (Greek, *oak-like*). *Polypodiaceae*. Some 10 or more E. Indian ferns, with round naked sori, as in *Polypodium*, but with a fine network of netted veins which are arranged in distinctly rectangular meshes. The most distinctive feature is in the shape of the lvs. which are either of 2 sorts, as in *Platynerium*, the cup lf. having the shape of an oak lf.; or the base of each lf. is separately lobed and oak-like. *D. quercifolia*, with 2 sorts of lvs., the spore-bearing 2–3 ft. long, is the commonest species. *D. rigidula*, Swartz (*D. diversifolia*, R. Br.), a similar but larger species from the same region also appeared at one time in the American trade, but the species are seldom seen in cult. in this country. *D. muscifolia* is occasionally seen in fine collections, where it is grown for its striking simple foliage, which reminds one of the bird's nest fern (*Asplenium nidus*). It is really a *Polypodium*, which see for description. R. C. BENEDICT.†

**DRYOPTERIS** (Greek, *oak-fern*). *Polypodiaceae*. WOOD-FERN. A widely distributed genus of handsome ferns with dissected foliage, the native species sometimes grown in the hardy border and the tropical kinds under glass.

Plants bearing round sori either naked or covered with heart-shaped or reniform indusia, which are fixed at the center or along the sinus: veins either wholly free or the lowest united.—Several hundred species have been referred to this genus. A considerable number of our common woods ferns belong to this genus. The species have been variously known under the names *Lastrea*, *Aspidium*, and *Nephrodium*. Other species sometimes referred to under this genus may be found under *Polystichum* and under *Lastrea*. For *D. acrostichoides*, see *Polystichum*; for *D. decurrens*, see

*Tectaria*. In N. Amer., known to many as *Aspidium*. For cult. see *Ferns*. Not the same as *Dryopteris*.

A. Veins entirely free.

B. Pinnæ lobed less than one-third to midrib.

1. *hirtipes*, Kuntze (*Nephrodium hirtipes*, Hook.). Lvs. rather rigid, 2-3 ft. long, 8-16 in. broad, on stalks clothed with dense black scales; pinnæ with broad, blunt lobes, the lower ones not reduced in size; sori medial on the lobes. India.

BB. Pinnæ cleft nearly to midrib, or lvs. bipinnate or tripinnatifid.

C. Texture thin, membranous; veins simple or once forked.

D. Lower pinnæ gradually reduced to mere lobes.

2. *noveboracensis*, Gray (*Aspidium noveboracense*, Swartz). NEW YORK FERN. Lvs. somewhat clustered from creeping rootstocks, pale green, 1-2 ft. long, tapering both ways from the middle. Canada to N. C. and Ark.

3. *Fischeri*, Kuntze (*Lastrea opaca*, Mett.). Lvs. 6-8 in. long, 2-3 in. wide, bipinnatifid, cut into close, entire lobes, the lowest much reduced; surfaces smooth. Brazil.

DD. Lower pinnæ scarcely smaller than those above.

E. Veins forked.

4. *Thelypteris*, Gray (*Aspidium Thelypteris*, Swartz). MARSH FERN. Rootstock creeping; lvs. scattered, clear green, 1-2 ft. long; margins of the spore-bearing pinnæ often strongly convolute; sori 10-12 to each segm. Canada to Fla. and Texas.—A form with pinnæ variously forked at tip is known as *Puffææ*.

EE. Veins simple.

5. *simulata*, Davenp. Rootstock creeping; lvs. yellowish green, scattered, 8-20 in. long, 2-7 in. wide, with 12-20 pairs of lanceolate pinnæ: sori rather large, some-

1363. *Dryopteris marginalis*. (Detail  $\times 1$ )

what distant, 4-10 to each segm. Native in N. Y. and New England, where it may be confused with *D. Thelypteris*. G.F. 9:485.

6. *patens*, Kuntze. Lvs. clustered at the end of a thick rootstock, 2-3 ft. long, 4-10 in. wide, soft-hairy beneath; pinnæ cut three-fourths to the midrib, the basal segms. usually longer. Fla. to Texas and Calif. and Trop. Amer. A.G. 20:25.

CC. Texture firm or subcoriaceous; veins 2-4 times forked.

D. Lvs. bipinnatifid or nearly bipinnate: indusia large, mostly flat.

7. *cristata*, Gray (*Aspidium cristatum*, Swartz). Lvs. 1-2 ft. long, with short, triangular pinnæ 2-3 in., long, are much wider at base. Var. *Clintoniana*, Underw. (probably a distinct species), is larger, with pinnæ 4-6 in. long, and with the sori rather near the midvein. Canada to Ark.; also in N. Eu.—Hybrids are described with *D. marginalis* and other species. G.F. 9:445.

8. *Goldieana*, Gray (*Aspidium Goldieanum*, Swartz). Lvs. growing in large crowns, 2-4 ft. long, 12-18 in. wide, the pinnæ broadest at the middle: indusia very large. Canada to Ky.—One of our largest and most stately native species.

DD. Lvs. mostly bipinnate: indusia convex, rather firm.

9. *Filix-mas*, Schott (*Aspidium Filix-mas*, Swartz). MALE FERN. Lvs. growing in crowns, 1-3 ft. long; sori near the midvein. Used as a vermifuge, as is also the next species. Eu., Canada and Colo.

10. *marginalis*, Gray (*Aspidium marginale*, Swartz). Fig. 1363. Lvs. 6 in. to 2 ft. long, growing in crowns, mostly in rocky places: sori close to the margin. Canada and southward.—One of our commonest ferns, and gathered with *D. spinuloso intermedia* for use with cut-fls.

DDD. Lvs. mostly tripinnatifid; segms. spinulose-toothed: indusia shriveling at maturity.

E. Lf.-stalks naked, polished.

11. *viridescens*, Kuntze. Lvs. 18-24 in. long, on stalks two-thirds as long; lower pinnæ largest: sori near the midribs. Japan.

EE. Lf.-stalks scaly.

12. *spinulosa*, Kuntze (*Aspidium spinulosum*, Swartz). Lvs. ovate-lanceolate, with a few pale, deciduous scales at the base; indusia smooth, without marginal glands. Var. *intermedia*, Underwood. Lvs. evergreen, the scales more persistent, with brown centers, and the margins of the indusia with stalked glands. One of our commonest wood ferns in the northern states. Extensively gathered for use with cut-fls. Probably a distinct species. Var. *dilatata*, Underwood, has similar scales to the last and tripinnate lvs. In woods at altitudes of 1,500 ft. upward, from Canada to Ore.; also in Eu. Probably a distinct species.

13. *Boottii*, Underwood (*Aspidium Boottii*, Tuckerm.). Lvs. elongate-lanceolate, with broadly oblong pinnules: indusia minutely glandular. Intermediate between *D. cristata* and *D. intermedia*. Probably a hybrid. Canada, N. Y. and New England.

DDDD. Lvs. ample, 4-5-pinnatifid.

14. *effusa*, Urban. Lvs. 3-4 ft. long, 2 ft. or more wide, with polished stalks and from short, creeping rootstocks: sori abundant, scattered, often without indusia. Cuba to Brazil.

1364. *Dryopteris parasitica*. ( $\times \frac{1}{2}$ )

15. *dissècta*, Kuntze (*Lastrea membranifolia*, Hort.). Lvs. 1-5 ft. long, 1-3 ft. wide, membranous, decompound; segms. broad and blunt; surfaces nearly naked: sori near the margin, abundant. India and Madagascar to Austral.

AA. Veins not entirely free, the lower veinlets of adjoining segms. united.

16. *Otària*, Kuntze (*Lastrea aristata*, Hort.). Lvs. 1 ft. long, with a long terminal pinna an inch or more wide, with lanceolate lobes, and 6-12 similar lateral pinnæ; texture thin; surfaces naked; veins united half-way from the midrib to the edge. Ceylon to the Philippines.—Good for table ferneries, but slow of growth.

17. *parasitica*, Kuntze (*Nephrodium môle*, R. Br. *D. môle*, Underwood, in preceding edition). Fig. 1364. Lvs. 1-2 ft. long, 8-12 in. wide, bipinnatifid, the pinnæ cut into blunt lobes; lower pinnæ distant from the others and somewhat shorter; surfaces finely villose. Tropical regions of both hemispheres.—Often grows as a weed in greenhouses.

18. *basilàris*, C. Chr. (*Nephrodium philippinense*, Baker. *D. philippinensis*, Underwood, in Cyclo. Amer. Hort.). Lvs. 2-3 ft. long, 12-18 in. wide, bipinnatifid, smooth, with a naked rachis; lower pinnæ scarcely smaller: sori midway from midrib to margin, with firm, smooth indusia. Philippines.

19. *crenàta*, Presl. Lvs. 1-2 ft. long, on stalks nearly as long, with a terminal pinnæ 6-8 in. long, often 2 in. wide, and 4-8 similar lateral pinnæ; margins bluntly lobed: sori near the main veins. Cuba and Mex. to Brazil.

L. M. UNDERWOOD.  
R. C. BENEDICT.†

**DRYPÈTES** (probably from Greek for *drupe*, from the character of the fruit). GUIANA PLUM. WHITEWOOD. *Euphorbiaceæ*. Tropical evergreen greenhouse shrubs. Glabrous: lvs. leathery, alternate, simple, mostly entire: fls. dioecious, in axillary clusters or pistillate single, apetalous, staminate fls. with calyx imbricate and a rudimentary pistil; stigma broad, nearly sessile; pistil 1-celled, 2-ovuled.—About 10 species in Trop. Amer., 2 native in S. Fla. They do well in light loam. Prop. from cuttings in sand with heat. *D. lateriflora*, Urban (*D. crœcea*, Poit. *Schæfferia lateriflora*, Swartz), of W. India region, 6 ft. high, lvs. elliptical, pointed, has been in cult.

J. B. S. NORTON.

**DUCHÉSNEA** (A. N. Duchesne, monographer of *Fragaria* in 1766). *Rosaceæ*. Strawberry-like perennial trailing herbs, differing in the calyx being 5-parted and the lobes alternating with larger leafy 3-5-toothed bracts, the petals yellow, and the receptacle dry and spongy rather than becoming fleshy or pulpy as in the strawberry: lvs. ternate, with short-stalked lflets: fls. solitary, on the runners; stamens 20-25, short.—Two species in S. Asia, one of which has run wild in this country, and is useful as a basket-plant and as a low ground-cover.

*indica*, Focke (*Fragaria indica*, Andr.). **YELLOW STRAWBERRY**. A neat plant trailing close on the ground, with leafy runners, pubescent: lflets rhombic-ovate, more or less petioled, coarsely crenate, obtuse: fls. about  $\frac{3}{4}$  in. across, on peduncles equaling or exceeding the lvs.: fr. usually less than  $\frac{1}{2}$  in. diam., red, insipid. In waste grounds, N. Y., west and south.

L. H. B.

**DUCKWEED**: *Lemna*.

**DUCKWHEAT**: *Fagopyrum*.

**DUDAIM MELON**: *Cucumis*.

**DUDLEYA** (named for the late Wm. R. Dudley, professor of botany in Stanford University). *Crassulacææ*. Shortly caulescent or acaulescent perennials, with flat, linear to ovate, acute basal lvs.: fls. in short

or elongated panicles, orange-yellow or red, rarely white: lvs. on flowering branches much shorter and relatively broader than the basal ones, sessile or clasping: corolla nearly cylindrical or slightly angled, the segms. united below the middle; stamens twice as many as the calyx-lobes: carpels erect, many-sided.—Some 60 species have been described, all from the west coast of N. Amer. None of them has proved very satisfactory as a bedding plant, and as a rule the species do not compare with the *echeverias* in horticultural value. The following species are described in this work under *Cotyledon* (p. 868):

*D. Cotyledon*, Brit. & Rose, as *C. californica*.  
*D. pulverulenta*, Brit. & Rose, as *C. pulverulenta*.  
*D. Purpusii*, Brit. & Rose, as *C. Purpusii*.  
*D. lanceolata*, Brit. & Rose, as *C. lanceolata*.

J. N. ROSE.

**DUGUËTIA** (named in honor of J. J. Duguet, who in 1731 wrote a work on plants). *Aberemôa*, R. E. Fries, not Aubl. *Annonacææ*. A genus of Trop. American shrubs and trees, about two dozen species, differing

1365. *Duguëtia quitarensis*. (Branch  $\times \frac{1}{2}$ )

from *Annona* in technical characters, particularly in imbricating petals and distinct angular rigid carpels becoming detached from the alveolate receptacle when mature, and usually with stellate-pubescent or scurfy indument. *D. lanceolata*, St. Hil., the type of the genus, is a Brazilian tree. *D. quitarensis*, Benth., Fig. 1365, with very similar fr. which turns red when ripe, has recently been collected on the Isthmus of Panama by Henri Pittier; and *D. furfuracea*, Benth. & Hook. f., a low plant with edible orange-colored fr. as large as an apple, in the province of Minas, Brazil, by Shamel, Popenoe, and Dorsett, of the Bureau of Plant Industry. From this genus must be separated *Fusæa longifolia*, Safford (*Annona longifolia*, Aubl.), the fr. of which is a solid globose syncarpium, and the outer circles of stamens sterile and petal-like, while the indument is composed of simple silky hairs. See *Fusæa*.

W. E. SAFFORD.

**DULÍCHIUM** (old Latin name). *Cyperaceæ*. One perennial species, *D. arundinaceum*, Brit. (*D. spathaceum*, Pers.), in E. N. Amer., which has been offered by collectors as a bog-plant. It is grass-like, with terete leafy culms which are hollow and unbranched, 2-3 ft. tall; it has linear flattened spikelets sessile in 2 ranks on peduncles that arise from the lf.-sheaths. It is distributed in swamps about ponds from Newfoundland across the continent and to Fla. and Texas; of no special value.

**DURÁNTA** (after Castor Durantes, physician in Rome and botanist, died about 1590). *Verbenaceæ*. Tropical American woody plants, some of which are cultivated outdoors in Florida and California, and in a few northern greenhouses.

Shrubs or trees, glabrous or woolly, often armed with axillary spines; lvs. opposite or in whorls, entire or toothed; racemes long and terminal or short and axillary; fls. small, short-pedicelled in the axis of a small bract; corolla-limb of 5 spreading oblique or equal lobes, the tube usually curved; stamens 4, didynamous; calyx enlarging and inclosing the fr.; stigma 4-lobed: fr. an 8-seeded juicy drupe.—Eight or 10 species, Mex., W. Indies, S. Amer., one reaching Key West.

**Plumieri**, Jacq. (*D. spinosa*, Linn. *D. inermis*, Linn. *D. repens*, Linn. *D. Ellisia*, Jacq. *Ellisia acuta*, Linn.). **GOLDEN DEWDROP**. A variable shrub or small tree, minutely pubescent or becoming glabrous: branches 4-angled: lvs. obovate, oblong, ovate or elliptic, mostly entire, contracted into short petiole: fls. in paniced loose racemes; calyx-teeth subulate; corolla lilac, the limb less than  $\frac{1}{2}$  in. across, the lobes ciliate; calyx yellowish, closed into a beak and covering the yellow drupe (which may reach about  $\frac{1}{2}$  in. diam.). Key West, W. Indies, Mex., to Brazil. B.M. 1759. B.R. 244.—Branches either armed or unarmed. Attractive forms with white fls. and with variegated lvs. are reported in cult.

**Loréntzii**, Griseb. Spineless, the branchlets 4-angled: lvs. small, coriaceous, ovate or elliptic, obtusish, strongly serrate toward apex, petioled: fls. in terminal interrupted racemes (white?); calyx tubular, 5-ribbed, short-toothed; corolla-tube exserted, cylindrical; corolla-limb unequally 5-parted, the lobes oval-orbicular; stamens included, didynamous: fr. a 2-pyrenous berry. Argentina; offered in S. Calif.

**stenostachya**, Tod. Closely allied to *D. Plumieri*. Spineless, to 15 ft. high, branchlets 4-angled: lvs. oblong-lanceolate, acuminate, serrate or entire, pubescent on the veins beneath, 3-8 in. long: fls. lilac, less than  $\frac{1}{2}$  in. across, pendulous in slender racemes, 3-4 at the end of the branches, in fr. 6-12 in. long: fr. yellow, about  $\frac{1}{3}$  in. across. Brazil. Offered in S. Calif.

L. H. B.

**DURAZNILLO**: *Jatropha*.

**DÛRIO** (from a Malayan vernacular). *Bombacaceæ*. Trees of the Indian archipelago and Malaysia, one of which yields the durian (*D. zibethinus*, Linn.), a much-prized fruit of the East. Fig. 1366. There are probably a dozen other species of Durio, mostly Bornean and recently described.

The durian is a tall tree (to 80 ft.), with oblong acuminate entire lvs., colored and scaly beneath, pinnately veined, coriaceous: fls. large, whitish, in lateral cymes or fascicles; calyx bell-shaped, 5-lobed, subtended by an involucre; petals 3; staminal column divided above into many filaments in 4-6 groups, the anthers twisted; ovary 5-celled, each cell many-ovuled, bearing a long style with a capitate stigma: fr. ovoid or globular, often 10 in. long, very spiny, somewhat woody, mostly indehiscent, the large seeds and carpels surrounded by a firm cream-colored edible pulp. The fr. has a strong offensive odor.

The durian is discussed as follows by O. W. Barrett in the Philippine Agricultural Review:

"The durian has an odor that can be compared only to a mixture of old cheese and onions, flavored with turpentine; but those who eat it love it so dearly that the smell does not bother them. . . . The fruit weighs about five pounds, nearly one-third of which is edible pulp and about one-sixth of which is edible seeds; the sugar-content is over 12 per cent, and it contains the same amount of starch besides. The tree is

1366. The durian—*Durio zibethinus*. ( $\times \frac{1}{4}$ )  
(From an early representation of the fruit.)

magnificent and stately, and grows usually in open country, in the edges of forests, around native villages, and in clearings.—It can hardly be called a cultivated tree; at least, it is hardly ever grown in orchards, although on the other hand it could hardly hold its own in the real wild. Throughout Malaysia it is considered the most delicious fruit. Europeans, of course, generally revolt at the unpleasant odor; a fair proportion, however, of the foreign residents soon grow to relish the durian. Although it would not be wise, perhaps, for one unaccustomed to the fruit to eat a large quantity of the pulp at one sitting, there is apparently no substance in it that would cause indigestion or any other result than a rather unpleasant breath for a few hours after eating. The chemical body which is responsible for the very pronounced odor is probably one of the sulfur compounds with some base perhaps similar to that of butyric acid.—Harvesting the durian is not attended with danger, for soon after it becomes mature the heavy fruit falls, and occasionally kills or severely injures the unlucky individual underneath."

The seeds are eaten roasted, and the unripe fruit boiled as a vegetable. The tree has been successfully introduced into Jamaica, but is not in general cultivation in that island.

The specific name, *zibethinus*, is said to be derived from the practice of using the decomposed fruit as a bait for the civet-cat or zibet. Fig. 1366 is reduced from Vol. 7 of the Trans. of the Linn. Soc., 1804, illustrating König's historic account of the fruit.

L. H. B.

**DUSTY MILLER**: *Lychnis Coronaria*; also species of *Centaurea* and *Senecio*.

**DUTCHMAN'S BREECHES**: *Dicentra Cucullaria*.

**DUTCHMAN'S PIPE**: *Aristolochia*.

**DUVÀLIA** (for Duval, an early botanist). *Asclepiadaceæ*. About 20 succulent very dwarf leafless herbs, mostly of S. Afr., rarely seen in cult.: sts. decumbent or erect, sometimes subterranean and with the tips appearing above the surface, 4-6-angled and with spreading teeth, each of which bears a minute rudimentary lf.: fls. solitary or in small clusters or cymes, usually borne near the middle of the young sts.; corolla rotate, deeply 5-lobed, with a cushion-like ring around the outer corona and supporting it; corolla-lobes linear-

lanceolate to ovate, folded longitudinally backward; corona double, from near the top of the staminal column, the outer one flat and entire and angled, the inner one with turgid more or less pointed lobes; stamens affixed in the base of the corolla, united into a tube around the ovary: fr. erect smooth follicles. Cult. of Stapelia and similar succulents. The species are essentially fancier's plants and apparently not in the trade.

**DUVERNØIA** (J. G. Duvernoy, pupil of Tournefort, or G. L. Duvernoy, of Strassburg, writer on natural history). *Acanthaceae*. By some authors united with *Adhatoda*, which genus is by some included in *Justicia*. The genus comprises 15 or more herbs or shrubs: fls. single or in short spikes; calyx short, 4-toothed, the back lobe toothed or parted; corolla-tube short; limb labiate, the upper lip helmet-shaped and 2-toothed, the lower lip flat. The species seem not to be in the trade, although *D. Dewèvrei*, DeWild, has been cult. in Belgium: it is a tufted herb, about 2 ft. high: lvs. oblong, petiolate; fls. paniculate; upper lip of corolla white with red stripes and the lower greenish white; corolla about  $\frac{1}{2}$  in. long. Congo.

**DWARFING.** Dwarf plants are those that never attain the height or size of the usual or representative individuals of the species. Some dwarfs are "natural," being represented by varieties of prevalingly small size; and these varieties usually reproduce more or less true from seed or cuttings. Thus there are dwarf petunias, lobelias, asters, cannas, peas, beans. Such dwarfing comes within the field of breeding.

The "artificial" dwarfs are produced by more or less arbitrary manipulation, as by grafting on stocks of small growth, heading-in the top or the root or both, by confining the roots, by withholding food and water, and by various forms of contortion and constriction.

Plants are dwarfed to keep them within bounds in small areas, to increase flower-bearing and fruit-bearing in proportion to the size of the subject, to bring all parts within reach and control, to express the skill and satisfy the conceit of the gardener, and to extend the range of interesting plant forms; and plants may be adapted to adverse soils or conditions by grafting on hardy or more reliable roots that may chance to have a dwarfing tendency. Dwarf plants are very useful in flower-gardens and in landscape work. The picturesque dwarfs of the Japanese type are amongst the most curious of plant forms.

#### The Japanese practice of dwarfing. Figs. 1367, 1368.

The art of dwarfing trees has been long practised among the Japanese gardeners. Some trees are more adapted for this purpose than others. The following have been considered to be most suitable:

*Chamacyparis obtusa*.  
*Pinus pentaphylla*.  
*Pinus parviflora*.  
*Pinus Thunbergii*.  
*Pinus densiflora*.  
*Larix leptolepis*.  
*Juniperus rigida*.  
*Juniperus chinensis* var. *procumbens*.  
*Podocarpus chinensis*.  
*Podocarpus Nageia*.  
*Tsuga Sieboldii*.  
*Tsuga diversifolia*.  
*Cryptomeria japonica*.  
*Acer palmatum*.

*Acer trifidum*.  
*Styrax japonica*.  
*Lagerstromia indica*.  
*Punica Granatum*.  
*Trachycarpus excelsa*.  
*Rhapis flabelliformis*.  
*Rhapis humilis*.  
*Zelkova acuminata*.  
*Milletia japonica*.  
*Wistaria floribunda*.  
*Wistaria brachybotrys*.  
*Prunus Mume*.  
*Evonymus alata*.  
*Cycas revoluta*.

Various species of Japanese flowering cherries, ivies, bamboos, fruit trees, etc.

Before entering into a discussion of dwarfed trees, one should have a clear understanding between the "bonsai" or artistic plant and the "hachiuye" or ordinary potted plant.

There are two styles in which the "bonsai" is presented, one is the planting of one or more tiny trees of picturesque form in an artistic shallow pot; and the other is the representing of a part of a miniature garden or forest embracing trees, shrubs, grasses, mosses, rocks, and ponds. The former is simply an improved or

1367. Japanese dwarf tree.

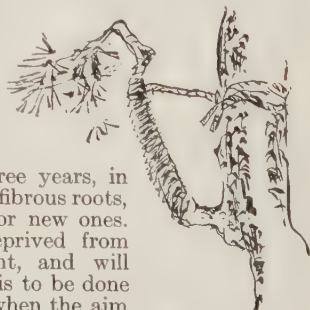

modified potted plant, whereas the latter exhibits an imaginary scene, so that one might feel by glancing upon the pot in a little Japanese chamber as if he were at that moment strolling in such a garden or wandering with-in forest. A little piece of stone gives an idea of Mt. Fuji, and a drop of water the surface of the Japan Sea. We often suspect the tree, covered with

mossed bark, of not more than  $\frac{1}{2}$  foot in height, would reach the cloud; or it might suggest a wintry landscape brought in amidst scorching summer days to release a man from heat.

The success in raising a valuable "bonsai" depends entirely on the skill of dwarfing the trees, and it requires a long experience. Remember always what the home of the plant was, and treat it according to its habitat. In other words, climate, soil, environment, nourishment, and all other circumstances of its original state should accompany the tree; and the degree of humidity, both in the air and ground, is of prime importance in the dwarfing process. Some have the erroneous notion that the dwarfing is accomplished merely by bending the tree unnaturally. The roots are confined to check growth, without making other alteration. The shape and size of the branches or leaves are affected by the firmness of the earth, the way of watering, the kinds of fertilizer, and the degree of sunshine. Between the leaves there should be ample air and frequent sunshine. Some plants need only slight moisture, and others much. Too wet is worse than too dry. Many are thoughtless in giving water, not considering the condition of the soil. Judicious watering is one of the first requisites to success. For example, after being placed on balconies or terraces in the daytime, the potted plants should be exposed outdoors during the night, if not stormy. Japanese gardeners use many different fertilizers in accordance with the time of growth, kind of plant, and purposes (i.e., whether for branches or leaves, for flowers or fruits), some of them being: oil-cake, bone-meal, tankage, clam-shells, barn-manures, night-soil, wine lees, tea dregs, cow's milk, rice-bran, fish refuse, iron-rust, and others.

Plants both of "bonsai" and "hachiuye" dwarfs should be repotted every two or three years, in order to destroy the old fibrous roots, and to give a chance for new ones. Otherwise, trees are deprived from taking any nourishment, and will soon die. This practice is to be done in February or March, when the aim of dwarfing is completed; whereas the pruning is to be between April and June, to secure more or even larger flowers.

**Pine.**—This is one of the most difficult plants to be treated as a dwarfed tree, although it will hardly result in failure, if taken direct from the mountain or seashore while new young needles are steadily growing. Pines that have suffered through various difficult

1368. Training a branch.

weather are preferred. About half a year previous to removal, a ditch should be made around the plant. In removing, the main root should be carefully cut off by scissors, leaving its end downward to avoid the resin from accumulating, which otherwise might destroy the tree. For different shapes, the branches are to be twisted to and fro, as shown in the cut (Fig. 1368); bind the part with hemp-palm rope, and pull it moderately toward the trunk with a cord. The special nature of this tree is to dislike the humid earth. Having no pleasing flower or fruit, the pine must exhibit merit in the arrangement of needles or the color of the bark. The best time to transplant is in autumn. For fertilizers, one may use oil-cake or a bone-meal.

*Mume (Prunus Mume).*—This is different from the Japanese flowering cherry; the beauty of the flower should accompany the picturesque form of the tree itself. The age of the tree is highly regarded. Slender branches as well as grotesque trunks with mossy bark are usually chosen. Hence, all dwarfed Mume plants are raised by grafting. The potting of Mume may take place as soon as the flowers have fallen. The pot is to be kept in shade at least one month, the earth having been thoroughly pressed. To have more flowers, the old roots are destroyed, and the branches cut, leaving a few branchlets. Potted Mume is fertilized with thin liquid manure, oil-cakes or occasionally cow's milk, between December and February.

*Pomegranate.*—In this plant, the portion of the roots which is close to the main trunk may be exposed to the air. As a dwarfed tree, pomegranate is enjoyed both for fruits and flowers. All new sprouts are to be pinched off, other than those that will produce flowers. Until the fruits have grown larger, one should wait for manuring. For flowers, oil-cake, tankage, or bone-meal are used; for fruits a light fertilizer is used.

*Bamboos.*—Choose one of the most proper kinds and keep it in a pot for two or three years. Then wait upon several shoots coming up. One year after this, these new bamboos are transferred into other pots. The practice needs much patience and great skill, and it would hardly pay, knowing that the prime age of bamboo is only for four or five years. ISSA TANIMURA.

#### Dwarf fruit trees.

Generally speaking, dwarf trees are those which by various means are made to remain smaller than normal trees of the same species or variety. Three means are in common use in dwarfing trees: by growing on dwarfing stocks, restricting the root run, and by pruning to check or suppress the growth of the top. Horticulturally speaking, and particularly as the term is applied to fruit trees, dwarf trees are those which are grown on dwarfing stocks. A discussion of dwarf fruit trees is, then, most largely concerned with dwarfing stocks.

Dwarfing stocks are not modern innovations. For at least three centuries, various stocks have been used to dwarf apples, pears, plums, cherries and quinces. In fact, dwarf fruit trees were quite as common, or even more so, in Europe a century ago than they are at present. They have been grown in America, at least dwarf apples and pears, for nearly a century, during which time in recurring periods they have received much attention from fruit-growers. There is in horticultural literature much data, which, while fragmentary, is still substantial, to guide us in the use of dwarfing stocks and to indicate the value of dwarf fruit trees.

The action of dwarfing stocks is readily explained after a statement of what stocks are. A dwarfing stock is always a smaller, a weaker, or a slower-growing variety or species than the tree to be propagated on it. The top conforms to the roots chiefly because of the inability of the latter to furnish sufficient nutrition. The tree is dwarfed through starvation. Other than

in size the trees are little or not at all affected, although minor changes in the fruit and in the bearing habit are supposed to be brought about by dwarfing.

Dwarf fruit trees are propagated by the same methods employed in growing standard trees with preference given to budding dwarfing stocks, whereas standard trees are still largely propagated by grafting. Propagators hold that a better union can be obtained by budding than by grafting, and since it is always difficult to secure a good union between plants as widely divergent as stock and cion in a dwarf tree must of necessity be, budding should have the preference of the two methods. In fact the chief problem in growing dwarf fruit trees is to find a stock with which the larger growing cion can easily be worked and with expectations of a close and permanent union. This brings us to the matter of stocks for the several fruits.

Dwarf apples are commonly grown on two stocks—the Paradise and the Doucin. Both of these, it must be understood, are class names, there being in the literature a dozen or more varieties of Paradise and about as many of the Doucin. Carefully compared, the many kinds in use can be reduced to the French Paradise (Pommier du Paradis), English Paradise, and the Dutch Paradise for the first class, while the Doucin stocks may be grouped under the Doucin, the English Broad-leaved and the English Nonsouch. There is much confusion in the names of dwarf apple stock in nurseries and the grower will be fortunate if he gets what he calls for. Of these two classes, the Paradise stocks make the dwarfier plants and should be used for trees to be kept as true dwarfs and for all that are to be trained in fancy forms. The Doucin stocks are the better for free-growing trees.

Pears are dwarfed by growing on quince roots. Any quince may be used, but the Angers, upon which quinces are commonly propagated, is the best dwarfing stock for the pear. Comparatively few pears can be successfully worked on quince roots because stock and cion do not make a good union. This antipathy is obviated by budding the quince with a pear which unites readily; the next year the untractable variety is budded on the more amenable variety, the resulting tree being thus pear on quince, followed by pear on pear—the "double-working" of nurserymen.

There is no question but that the Mahaleb is a dwarfing stock for the cherry, and in Europe, where it has long been used, it is always regarded as such. In America, where the Mahaleb in the last quarter century has all but superseded the Mazzard, a free-growing stock, it is not so commonly known that there is a difference in the size of trees on the two stocks. It must not be understood that the Mahaleb stock gives a true dwarf cherry, but it has a very decided dwarfing effect on either sweet or sour cherries.

Stocks for plums have not been well tested—a statement that holds for all stone fruits. It is very certain, however, that varieties of *Prunus insititia*, as the Damsons or the St. Julien, the latter one of the best of all plums for a stock, have a dwarfing effect on the varieties of the larger-growing trees of *P. domestica*, as do also several of our free-growing native species, among which *P. americana* may be recommended for cold climates. For true dwarf trees, however, the only stocks that give promise are the dwarf natives, of which *P. pumila* and *P. Besseyi* have been found to unite readily with several varieties each of either the *Domestica* or *Triflora* plums, and to make very good dwarfing stocks for them.

Peaches, apricots and nectarines are dwarfed by budding on *P. cerasifera*, *P. insititia* and *P. americana*. It is probable that all of these fruits, and the cherry as well, can be grown on *P. pumila* and *P. Besseyi* as true dwarfs, several experiments having demonstrated that good unions form between the peach, at least, and these dwarf sand cherries. As to whether the union

would be sufficiently permanent to make the trees so obtained worth while, remains to be seen.

The great advantage of a dwarf tree is its small size, which permits the planting of more varieties of a fruit in a small space. Dwarf fruits, then, deserve, in particular, the consideration of amateur fruit-growers and of those who want small-growing fillers for permanent orchards. Trees of small size are easier to prune, spray, and to care for in every way. Because of the low stature and compact head of the dwarfs, wind causes less injury to trees and crops.

1369. *Dyckia rariflora*.

Another very material advantage of the dwarfs is that they come into bearing earlier than the standards. The desirability of early bearing from several standpoints is obvious. Advocates of dwarf fruits very generally assert that the fruit from the dwarf trees is of higher quality, higher color and better flavor. As a generalization, this is not true, though it probably is true for a few varieties of each of the several fruits under consideration. Tests of many varieties of apples on dwarf and standard stocks on the grounds of the New York Agricultural Experiment Station show that more often the fruit from standard trees is the better. Pear-growers have found that comparatively few varieties of this fruit are improved in the qualities named by growing as dwarfs. Size, color and quality of fruit are as likely to be affected deleteriously as beneficially by dwarfing.

Dwarf stocks are much used to adapt varieties to soils. This is the chief value of most of the propagating plants named for the stone-fruits. The true purpose of such stocks must be clearly kept in mind—the dwarfing in this case is a disadvantage attendant upon the use of the stock for another purpose.

The disadvantages of dwarfing stocks, in America at least, are rather more pronounced than their advantages. They may be summed up as follows: Nearly all dwarf trees are shorter-lived than standards—the exceptions are very few. All dwarf trees, whether trained in fancy forms or free-growing, need more care than standard trees. The chief items needing extra care are pruning, tilling and fertilizing. It is more difficult to propagate dwarf trees and the cost of the plants is therefore greater, making the cost an acre, with the increased number of trees, much greater. Lastly, it is most difficult to secure trees, especially of apples, on dwarfing stocks that are known to be true to name.

In conclusion, it may be said that we have just passed through one of the recurring periods of interest in dwarf trees in America and that commercial fruit-growers are more than ever convinced that for the present, at least, dwarf trees are of little value to them. The place of these trees is in gardens of amateurs and on the estates of those who can afford to grow and

train them for their beauty as well as for their fruit. There is, however, a possible future for dwarf fruits in commercial plantations, when the refinements of horticulture have been carried far enough to show the special adaptations of varieties of the several fruits to different stocks and when the care of dwarf trees is better understood.

U. P. HEDRICK.

**DYCKIA** (after Prince Salm-Dyck, German botanist, and author of a great work on succulent plants). *Bromeliaceæ*. Succulents, grown under glass and in the open far South.

Dyckias somewhat resemble century plants, but with smaller spines, as a rule, and flowering regularly. They are usually stemless, and the lvs. form dense rosettes. —About 60 species in S. Amer. For cult., see *Agave*. They are rarely cult. in Fla. and Calif., and in a few northern collections. Following have showy yellow fls.

A. Infl. amply branched or paniced.

*altissima*, Lindl. (*D. princeps*, Lem.). Lvs. spiny at the margin; floral bracts small, all manifestly shorter than the fls. Brazil.

AA. Infl. not branched, a raceme or spike.

B. Filaments forming a tube: fls. with scarcely any pedicel.

*rariflora*, Schult. Fig. 1369. Lvs. with small spines on the margin, shorter than in *D. altissima*; sepals not emarginate at the apex; upper sheaths of the scape shorter than internodes. Brazil. B.M. 3449. B.R. 1782.

BB. Filaments not forming a tube all the way: fls. with a short but conspicuous pedicel.

*sulphurea*, C. Koch, not Baker. Lvs. with small spines at the margin; sheaths of the scape longer than the internodes, the higher ones entire; bracts lanceolate, the lowest conspicuously longer than the pedicelled fls.; blades of petals wide and longer than stamens. Brazil.

WILHELM MILLER.

**DYPSIS** (obscure name). *Palmaceæ*, tribe *Arécææ*. Madagascan palms that have been poorly described, are little known and of scarcely any horticultural significance. They are all small, unarmed palms, with reed-like sts.: lvs. terminal, entire, bifid at the apex or pinnatisect; segms. split at the apex or irregularly toothed, the apical one confluent; sheath short; spadices loosely fld.: fr. small, oblong or ovoid, straight or curved, oblique at base.—Perhaps half a dozen species.

No species of *Dypsis* are common in cultivation, as they possess but little beauty. They are among the easiest and quickest to germinate. All of them require a stove temperature. *D. madagascariensis*, Nichols. is also known as *Areca madagascariensis*, Mart., and is so treated here. *D. pinnatifrons*, Mart. (*A. gracilis*, Thouars), is one of several plants that have been known as *Areca gracilis*. It is a pretty palm, now grown in large quantities by some dealers. G.C. II. 24:394. The genus is closely related to *Chamædorea*.

N. TAYLOR.†

**DYSCHORISTE** (name refers to the scarcely divided or lobed stigma). Incl. *Calophanes*. *Acanthaceæ*. Fifty or more annuals or perennials of the tropics of Amer., Afr., and Asia, allied to *Ruellia* and *Strobilanthes*. None of them is apparently in regular cult. They are plants with opposite mostly entire small lvs. and blue or pale fls. in short-stalked cymes. *D. nobilior*, C. B. Clarke (*D. Hildebrandtii*, Lindl.), is a free-flowering shrub, with a penetrating odor, and hairy branches; lvs. elliptic, nearly 2 in. long, slightly crenulate; fls. purple-blue in many distant and dense axillary cymes; corolla less than ½ in. long. Brit. Cent. Afr.; recently cult. at Kew.

# E

**EARTH-NUT, EARTH-PEA.** Little-used names for the peanut, goober or pinder, *Arachis hypogæa*. The words earth-nut and ground-nut are used for many subterranean tubers, without much discrimination, and therefore they have small value as vernaculars. They may be applied to the underground tubers of *Apios tuberosa*, *Panax trifolium*, *Erigenia bulbosa*, *Cyperus esculentus*, and others. Earth-apple, earth-gall and similar variants are in use for various plants.

**EATÔNIA:** *Sphenopholis*.

**ËBENUS** (Greek name for the ebony). *Leguminosæ*. About 15 species of silky-hairy herbs or sub-shrubs, of the eastern Medit. region and eastward to Beluchistan, allied to *Onobrychis*, sometimes planted in borders but apparently not offered in this country. Fls. reddish or purplish, papilionaceous, in dense axillary long-peduncled spikes; standard obovate or obcordate, narrowed to base; wings short or minute; keel about equaling the standard, the apex obtuse and oblique; calyx-lobes subulate and plumose: pod obovate or oblong, compressed, included in the calyx-tube, indehiscent, 1- or 2-seeded: lvs. odd-pinnate or some of them somewhat digitately 3-foliolate or even simple. *E. crética*, Linn., is shrubby with lvs. usually of 5 (sometimes 3) lfts., and reddish purple fls. in ovate-cylindrical spikes. Crete. B.M. 1092 (as *Anthyllis crética*). *E. Sibthorpii*, DC., is herbaceous, with more lfts., and purplish fls. in spherical spikes.

This genus has no relation to the ebony, which is of the genus *Diospyros* (particularly *D. Ebenum*).

**EBONY:** *Diospyros Ebenum*.

**ECBÁLLIUM** (Greek, *to throw out*). *Cucurbitacæ*. SQUIRTING CUCUMBER. A perennial trailing vine, easily grown as an annual in any garden, cultivated for its explosive fruits.

When ripe, the oblong prickly fr. squirts its seeds at the slightest touch, or sometimes at the mere vibration of the ground made by a person walking by. Some of the old herbalists called this plant *Cucumis asininus*. Another curious fact about the plant is that a powerful cathartic is made from the juice of the fr., which has been known for many centuries. A preparation of it is still sold in the drugstores as *Trituratio Elaterini*. The drug "elaterium" is derived from the juice of the fr. *Ecballium* has only 1 species, and is closely related to the important genera *Cucumis* and *Citrullus*. With them it differs from *Momordica* in lacking the 2 or 3 scales which close the bottom of the calyx. Other generic characters are: prostrate herb, fleshy, rough hairy: lvs. heart-shaped, more or less 3-lobed: tendrils wanting: fls. yellow, the staminate in racemes, pistillate usually from the same axils with the staminate fls.; calyx 5-cut. It is a native of the middle and eastern Medit. regions, especially in rich moist forests.

**Elatèrium**, A. Rich (*Elatèrium cordifolium*, Moench. *Momordica Elatèrium*, Linn.). SQUIRTING CUCUMBER. Fig. 1370. Described above; grown in this country as a curiosity. B.M. 1914.

WILHELM MILLER.

**ECCREMOCÁRPUS** (Greek, *pendent fruit*). *Bigoniaceæ*. An attractive half-hardy tendril-climber.

Shrubs, but grown as annuals in the N., tall climbing:

lvs. opposite, 2-parted or -pinnate: fls. yellow, scarlet or orange, mostly racemose; calyx campanulate, 5-parted; corolla-tube elongated; limb more or less 2-lipped or in *E. scaber* small and nearly entire; stamens 4, didynamous, included; disk annular: fr. an ovate or elliptic loculicidal 1-celled caps.—Three or 4 species of tall somewhat woody plants from Peru and Chile, climbing by branched tendrils at the end of the twice-pinnate lvs., and having very distinct fls. of somewhat tubular shape, which are colored yellow, orange or scarlet.

*Eccremocarpus* has two sections, in one of which the corollas are cylindrical, but in the section *Calampelis*, to which *E. scaber* belongs, the corolla has a joint at a short distance beyond the calyx, then swells out on the under side, and suddenly constricts into a neck before it reaches the small circular mouth, surrounded by five very short rounded lobes.

**scàber**, Ruiz & Pav. (*Calampelis scàber*, D. Don). About 10 ft. high: lvs. bipinnate; lfts. obliquely cordate, entire or serrate: fls. 1 in. long, orange, in racemes. July, Aug. Chile. B.R. 939. B.M. 6408. Var. **coccineus**, Hort., has scarlet fls. Var. **aureus**, Hort., has fls. bright golden yellow. Var. **carmineus**, Hort., has fls. carmine-red.—*E. scaber* is hardy in the southern parts of the U. S., and makes a most attractive perennial woody subject. It is also satisfactory in the open in the N. if given a warm exposure, blooming readily from seed the first year.

L. H. B.†

**ECHEVÈRIA** (named for Atanasio Echeverria, an excellent Mexican botanical draughtsman). *Crassulacæ*. Stemless or somewhat caulescent succulents.

Leaves fleshy, but usually broad and flat, commonly making dense rosettes: fls. borne in loose spikes or racemes or sometimes paniculate, but never in a flat cyme; calyx deeply 5-parted; sepals usually elongated and narrow, unequal, commonly spreading but sometimes erect; corolla 5-angled, usually strongly so, very broad at base; stigma-lobes united below, very thick

and nerveless, erect but often spreading at tip; stamens 10, 5 attached near the middle of the petals, the other 5 either free or attached lower down on the corolla: carpels 5, erect; ovules and

1370. *Ecballium Elaterium*. (×½)

seeds many.—More than 60 species of this genus have been described. Most of them have been in cult. in Washington and at the New York Botanical Garden, although but few are in the trade. It is confined almost entirely to Mex., one species extending into the mountains of W. Texas, and one or two species extending into Cent. Amer. Many of the species are valuable for flat bedding on account of their compact rosettes and highly colored foliage. For cultural notes, see *Cotyledon* (with which it has been united by many authors).

## INDEX.

*amœna*, 1.  
*atropurpurea*, 9.  
*campanulata*, 25.  
*carnicolor*, 12.  
*coccinea*, 4.  
*elegans*, 17.  
*fulgens*, 24.  
*gibbiflora*, 26.  
*glauca*, 19.  
*linguæfolia*, 6.

*lurida*, 10.  
*maculata*, 13.  
*metallica*, 26.  
*microcalyx*, 2.  
*mucronata*, 3.  
*Peacockii*, 15.  
*Pringlei*, 8.  
*pubescens*, 5.  
*pulvinata*, 7.  
*Purpusii*, 2.

*racemosa*, 11.  
*rubromarginata*, 21.  
*sanguinea*, 9.  
*Scheerii*, 23.  
*secunda*, 20.  
*setosa*, 14.  
*simulans*, 18.  
*subrigida*, 22.  
*subsessilis*, 16.

A. *Sepals orbicular, very small, obtuse.*

B. *Corolla twice as long as thick; sepals appressed.*

1. *amœna*, De Smet. Nearly stemless, with numerous offshoots: lvs. in small but dense rosettes: flowering branches slender, 4-8 in. long; fls. 1-8, in slender racemes; corolla red, 4-5 lines long. Native of Mex.—This species was intro. into cult. nearly 40 years ago.

BB. *Corolla little longer than thick; sepals not appressed.*

2. *microcalyx*, Brit. & Rose (*E. Purpusii*, Brit.). Shortly caulescent, sometimes 1 ft. high: corolla yellow-pink, 4 lines long. Native of Mex.

AA. *Sepals linear to ovate.*

B. *Fls. axillary, arranged in loose spikes or racemes.*

c. *The fls. in spikes.*

D. *Plant not caulescent, glabrous throughout.*

3. *mucronata*, Schlecht. Caulescent, glabrous throughout: basal lvs. in a dense rosette 4-8 in. long; fls. sessile; corolla 1 in. or more long, reddish tinged with yellow. E. Mex.

DD. *Plant caulescent, pubescent throughout.*

4. *coccinea*, DC. (*Cotyledon coccinea*, Cav.). St. 1-2 ft. high, finely grayish pubescent: lvs. oblanceolate, largest 8-9 in. long; infl. a spike of 15-25 fls. Common in Cent. Mex. Page 870.

5. *pubescens*, Schlecht. (*Cotyledon pubescens*, Baker). A similar species is sometimes cult., with obovate-spatulate lvs.

CC. *The fls. in racemes.*

D. *Species caulescent.*

E. *Infl. compound below; corolla pale.*

6. *linguæfolia*, Lem. Sts. 1 ft. or more high, very leafy: lvs. thick, fleshy, green, nearly terete at base: flowering branches long and drooping, each consisting of a simple raceme: fls. cream-colored. Mex.—This species has long been in cult., and has not been collected wild in recent years. It is so very different from the other echeverias of Mex. that we are led to suspect that it may be of hybrid origin.

EE. *Infl. simple throughout; corolla bright-colored.*

F. *Plant pubescent throughout.*

7. *pulvinata*, Rose (*Cotyledon pulvinata*, Hook.). Sts. 4-6 in. high, somewhat branching, becoming naked below: young branches, lvs. and sepals covered with a velvety pubescence: lvs. clustered in rosettes at the top branches, about 1 in. long, very thick; fls. in a leafy raceme; corolla scarlet, sharply 5-angled. Mex.—This is a very distinct echeveria, with a remarkable pubescence.

8. *Pringlei*, Rose (*Cotyledon Pringlei*, Wats.). This is perhaps nearest *E. pulvinata*, although not so pubescent nor so attractive a plant.

FF. *Plant glabrous throughout.*

9. *atropurpurea*, Baker (*Cotyledon atropurpurea*, Baker. *E. sanguinea*, Morr.). Sts. 4-8 in. high, glabrous throughout: lvs. aggregated at the top of the st. in a dense rosette, usually dark purple above, somewhat glaucous: flowering branches elongated; sepals somewhat unequal; corolla bright red, strongly angled. Probably native of Mex., but known only from cult. specimens. Page 870.

DD. *Species not caulescent.*

10. *lurida*, Haw. (*Cotyledon lurida*, Baker). Plants stemless, glabrous and glaucous throughout: lvs. forming a flat, rather open rosette, narrowly oblong, 2-4 in. long, acute, tinged with purple, especially when old: flowering branches 12-32-flid.; sepals thick, spreading or even reflexed; corolla bright red. Known only from garden material, but undoubtedly from Mex. B.R. 27:1.

11. *racemosa*, Schlecht. & Cham. This is similar to *E. lurida*, and was considered by Baker to be a synonym; but they are here kept distinct. The material of *E. racemosa* now in cult. was secured at the type locality of the species, Jalapa, Mex.

12. *carnicolor*, Morr. (*Cotyledon carnicolor*, Baker). Another somewhat similar species, but with only 6-8 fls. It is known only from garden specimens.

13. *maculata*, Rose. This belongs also to this alliance, but grows at higher localities in Mex., and has brighter green lvs. It ought to live throughout the year in our southern gardens.

BB *Fls. terminal, arranged in second spikes or racemes, either simple or compound.*

c. *Infl. a simple raceme.*

D. *Plant hairy throughout.*

14. *setosa*, Rose & Purpus. Plants stemless, giving out offsets from the base: lvs. often 100 or more, forming a dense, almost globular, rosette, thickish but flattened, about 2 in. long, covered on both sides with setiform hairs: infl. usually a simple second raceme with 8-10 fls.; petals red at base, yellow at tip, setose without. Contr. Nat. Herb. 13: pl. 10.—A very peculiar species, recently collected by C. A. Purpus in Puebla, Mex.

DD. *Plant glabrous throughout.*

E. *The fls. sessile.*

15. *Pæacockii*, Croucher (*Cotyledon Pæacockii*, Baker). Stemless: lvs. about 50 in a close rosette, obovate, spatulate, white-glaucous, slightly red toward the tip, faintly keeled on the back: flowering branches forming a scorpioid spike; corolla bright red, 6 lines long. It is doubtless of Mexican origin, although often reported as from New Mex. or Calif. Page 870.

EE. *The fls. pedicelled.*

F. *Lower pedicels short.*

16. *subsessilis*, Rose. This is very similar to *E. Peacockii*, but has shortly pedicelled fls. It is a very beautiful species, well suited for flat bedding. Native of Cent. Mex.

FF. *Lower pedicels elongated.*

G. *Lvs. very turgid.*

17. *élegans*, Rose. Stemless: lvs. numerous, sometimes 80-100 in cult. specimens, forming very compact rosettes, very glaucous, pale bluish green, very turgid, with translucent margins, these sometimes reddish: flowering branches pinkish, with 8-12 lvs.; fls. in a succulent raceme; corolla 5 lines long, its segms. distinct nearly to the base, pinkish with yellow spreading tips.—Known only from material collected near Pachuca, Mex., by J. N. Rose. This is one of the most beautiful species of the genus, and is well suited for rockeries or for use in flat bedding. This is not to be confused with *Cotyledon elegans*, N. E. Br., which is *Oliveranthus elegans*.

18. *simulans*, Rose. A similar species with somewhat different habit and lvs., and with slightly different corolla; sepals appressed rather than spreading.

GG. *Lvs. not turgid.*

H. *The lvs. glaucous green.*

19. *glauca*, Baker (*Cotyledon glauca*, Baker). Stemless: lvs. in small but dense rosettes, nearly orbicular,

broadened just above the apex, almost truncate, but with a decidedly purple mucro, very pale, slightly glaucous: fls. 15-20 in a small secund raceme. Cent. Mex.—Often confused with *E. secunda*, but apparently specifically distinct. Page 870.

HH. *The lvs. with reddish margins.*

20. *secunda*, Booth (*Cotyledon secunda*, Baker). Fig. 1083. Stemless, glabrous: lvs. numerous, inclined to be erect, forming a dense rosette, bluish green, ovate-cuneate, broad at margin and more or less reddish: fls. 12-15 in a secund raceme. Mex. Page 870.

CC. *Infl. a compound raceme.*

D. *Plants acaulescent.*

E. *Sepals widely spreading.*

21. *rubromarginata*, Rose. Stemless or sometimes with a short st.: lvs. comparatively few, stiff, ascending, glabrous, glaucous, with a somewhat crenulate, red margin: flowering sts. sometimes a foot high, more or less paniculate. Mex.

EE. *Sepals erect and closely appressed to the corolla.*

22. *subrigida*, Rose (*Cotyledon subrigida*, Rob. & Seaton). Stemless, glaucous throughout: lvs. in a dense rosette, flat, acute, very glaucous, bluish green, tinged with purple; the margins of young ones bright scarlet. Mex.—This is one of the most beautiful of all the echeverias. It is especially suitable for growing in clusters.

DD. *Plants caulescent.*

E. *Shape of lvs. acute.*

F. *Lvs. tapering into a long narrow stalk.*

23. *Scheerii*, Lindl. (*Cotyledon Scheerii*, Baker). Sts. sometimes 2 ft. tall, or more often branched, glabrous, and somewhat glaucous: infl. a few-branched panicle; petals red or tinged with yellow, thick, erect or spreading at tip. Undoubtedly Mex., but known only from cult. material. B.R. 31:27. Page 870.

FF. *Lvs. somewhat narrowed downward, but with a broad base.*

24. *fülgens*, Lem. (*Cotyledon fülgens*, Baker). Sts. usually 4-8 in. high, glabrous throughout: lvs. few in each rosette: infl. paniculate; corolla strongly 5-angled, coral-red without, yellowish within. Mex. Page 870.

EE. *Shape of lvs. obtuse.*

F. *Lvs. rounded on the face.*

25. *campanulata*, Kunze. Short, caulescent, the branches crowned by rosettes of large lvs.: lvs. spatulate, tapering into thick petioles, very glaucous, obtuse at apex: petals thick, reddish without, yellowish within, somewhat spreading at tip. Mex. B.R. 1247 (as *E. gibbiflora*).—It is said to be near *E. gibbiflora*, but it certainly has very different foliage.

FF. *Lvs. concave or flat on the face.*

26. *gibbiflora*, DC. Sts. often tall, 2 ft. or more high, glabrous throughout: lvs. 12-20 in a close rosette, obovate-spatulate, often highly colored: infl. a lax panicle. Mex. Var. *metallica*. A very common and popular greenhouse plant. It is very similar to the type, but has more highly colored lvs. Page 870.

*E. argentea*, Lem., I.H. 10: Misc. 78, 1863=Dudleya pulverulenta.—*E. Bernhardiana*, Foerst., is a garden species or form from an unknown source.—*E. bracteosa*, Lindl. & Paxt.=Pachyphytum sp.—*E. cinerea* is listed in Johnson's Gardener's Dict., p. 264, 1894, as a hybrid.—*E. clavifolia*, Deleuil, is a hybrid of Pachyphytum bracteolusum and Courantia rosea.—*E. Clavelandii* is a hybrid in cult. at the White House, Washington.—*E. cyanea*, Johnson Gard. Dict., is a garden hybrid.—*E. dealbata*, Johnson Gard. Dict. garden hybrid.—*E. Desmetriana*, L. De Smet=E. Peacockii.—*E. erecta*, Deleuil, is said to be a hybrid of *E. coccinea* and *E. atropurpurea*.—*E. ferrea*, Deleuil, said to be a hybrid of *E. Scheerii* and *E. Calophana*.—*E. globosa*, Hort. ex. E. Morr. in B.H. 24:161. (1874.) Caulescent or nearly so: lvs. numerous, forming a dense rosette, spatulate, pale and somewhat glaucous, about 3 in. long, broadest near the top and there  $\frac{1}{2}$ -1 in. broad,

mucronate at tip, rather flat: flowering branches weak and spreading, bearing a few linear bracts, branched at top into 2 secund racemes; sepals linear, very unequal, somewhat ascending; corolla both before and after flowering strongly 5-angled, reddish below, yellowish above and within; petals free nearly, if not quite, to the base; stamens opposite the petals borne on the lower third of the corresponding petals; the 5 alternate stamens free nearly to the base: carpels free, erect. This description is drawn from a plant in the Washington Botanical Garden of unknown origin. It resembles somewhat *E. secunda*.—*E. grandiflora*, E. Morr., is evidently a typographical error for *E. grandifolia*, Haw.—*E. grandidis*, E. Morr.=*E. gibbiflora*(?).—*E. grandidisepala*, Deleuil, is said to be a hybrid of *E. metallica* and a Courantia.—*E. herbacea*, Johnson Gard. Dict., is a garden hybrid.—*E. imbricata*, Deleuil, Cat. 1874; Deleuil in E. Morr. B.H. 24:329. (1874.) Deleuil in A. De Smet. R..B. 3:147. (1877.) This is cult. in the Washington Botanical Garden, and in the White House grounds. This species seems to be a favorite as a border plant in Washington City parks. It is said to be a cross between *E. glauca* and *E. metallica*. The infl., while secund as in *E. glauca*, is generally, although not always, 2-branched, while the lvs. are larger than in the true *E. glauca*.—*E. metallica decora*, Rodgers, I.H. 30:505, is a variegated form of *E. metallica*.—*E. mirabilis*, Deleuil, is a hybrid.—*E. mutabilis*, Deleuil, is said to be a hybrid of *E. Scheerii* and *E. lingulefolia*.—*E. ovata*, Deleuil, is said to be a hybrid of *E. Scheerii* and *E. metallica*.—*E. pachyphytioides*, L. De Smet, is a cross of Pachyphytum bracteolusum and *E. metallica*.—*E. pruinosa*, Deleuil, is said to be a hybrid between *E. lingulefolia* and *E. coccinea*.—*E. pulverulenta*, Nutt.=Dudleya.—*E. Pirpusii*, Schum.=Dudleya.—*E. rosea*, Lindl. & André. I.H. 20:124, said to be close to *E. secunda*; locality not given.—*E. rosea*, Lindl.=Courantia.—*E. scaphylla*, Deleuil, is a hybrid of Urbina agavoides and *E. lingulefolia*.—*E. securifera*, Deleuil, is a hybrid.—*E. spathulata*, Deleuil, is a hybrid.—*E. spiralis*, Deleuil, hybrid.—*E. stellata*, Deleuil, hybrid.

J. N. ROSE.

ECHIDNÓPSIS (viper-like, alluding to the serpent-like sts.). *Asclepiadaceæ*. A few species of leafless succulents of Trop. Afr. and Arabia, not sufficiently distinguished from Caralluma; allied to Stapelia, which see for cult. None of the species seems to be in the trade. The sts. are many-angled and tessellate, bearing small mostly fascicled fls. in the grooves: corolla rotate or approaching campanulate, 5-lobed, fleshy, yellow or purple-brown; staminal column very short and arising from the base of the corolla, and bearing the corona. The following species have recently been mentioned in garden literature: *E. cereiformis*, Hook. f. is 6 in. high, with elongated cylindrical serpentine or pendulous sts. and bright yellow fls. in fascicles. B.M. 5930. *E. Dammanniana*, Spreng. not Schweinf., is similar but has dark brown-purple fls. Nile Land. *E. Béntii*, N. E. Br., has 7-8-ribbed sts.  $\frac{3}{4}$  in. or less diam. and vinous-purple fls. in pairs toward the tips of the branches. S. Arabia. B.M. 7760. *E. somalensis*, N. E. Br., has columnar cereus-like shrubby cylindrical 6-8-furrowed branches, and nearly sessile dark purple yellow-spotted fls. solitary or in 2's or 3's. Somaliland. B.M. 7929.

ECHINACEA (Greek, *echinos*, hedgehog; alluding to the sharp-pointed bracts of the receptacle). *Compositæ*. PURPLE CONE-FLOWER. Perennial stout herbs, more or less grown in the border or wild garden.

Closely related to Rudbeckia, but rays ranging from flesh-color, through rose, to purple and crimson (one species, not in the trade, has fls. yellow to red), while those of Rudbeckia are yellow or partly (rarely wholly) brown-purple: the high disk and the downward angle at which the rays are pointed are features of echinaceas; the disk is only convex at first, but becomes egg-shaped, and the receptacle conical, while Rudbeckia has a greater range, the disk from globose to columnar, and the receptacle from conical to cylindrical; heads many-fld., mostly large; disk-fls. fertile, rays pistillate but sterile; pappus a small-toothed border or crown: sts. long and strong, nearly leafless above, terminated by a single head.—Five species in N. Amer., 2 of them from Mex., the others native to the U. S. By some treated as a section of Rudbeckia; by others now called Brauneria, which is an older name.

Echinaceas and rudbeckias are stout, and perhaps a little coarse in appearance, but their flower-heads, sometimes 6 inches across, are very attractive, and borne in succession for two months or more of late summer

With the growing appreciation of hardy borders and of native plants, it should be possible to procure four or five distinct colors in the flower, associated with low, medium and tall-growing habits. They do well in ordinary soils, and may be used to help cover unusually dry and exposed spots.

They respond well to rich soil, especially sandy loam, and prefer warm and sunny sites. They are perennials of easy culture. Propagated by division, though not too frequently; sometimes by seeds. The roots of *E. angustifolia* are black, pungent-tasted, and are included in the United States pharmacopœa as the source of an oleo-resin.

**purpurea**, Moench. (*Brauneria purpurea*, Brit.). Commonly not hairy, typically taller than *E. angustifolia*, 2 ft. or more high: lvs. ovate-lanceolate, or the lower ones broadly ovate, often 5-nerved, commonly denticulate or sharply serrate, most of them abruptly contracted into a margined petiole; upper lvs. lanceolate and 3-nerved: rays at first an inch long and broadish, later often 2 in. long or more, with the same color-range as *E. angustifolia*, but rarely almost white. Rich or deep soil. Va. and Ohio to Ill. and La. G.L. 19:28. G.M. 22: suppl. Nov. 11; 31:374. Gng. 5:41. Var. **serotina**, Bailey (*Rudbeckia purpurea* var. *serotina*, Nutt. *R. serotina*, Sweet). The varietal name means late-flowering, but the chief point is the hairy or bristly character of the plant. L.B.C. 16:1539. P.M. 15:79 (as *E. intermedia*).—Perhaps the best form for garden purposes, the rays said to be much brighter colored, broader and not rolling at the edges.

**angustifolia**, DC. (*B. angustifolia*, Brit.). Bristly, either sparsely or densely: lvs. narrower than in *E. purpurea*, from broadly lanceolate to nearly linear, entire, 3-nerved, all narrowed gradually to the base, the lower into slender petioles: fl.-heads nearly as large as in *E. purpurea*, but sometimes much smaller. Prairies and barrens, Sask. and Neb. to Texas, east to Ill., Tenn. and Ala. B.M. 5281. G.W. 4:164.—This species has several forms, which approach and run into *E. purpurea*.

A dealer advertises (1912) a "red sunflower" obtained by crossing a species of Echinacea with *Helianthus multiflorus*. It is described as 5-6 ft. high, with fls. 4-7 in. diam., red. See *Helianthus*.

N. TAYLOR.†

**ECHINOCACTUS** (Greek, *spine* and *cactus*). *Cactaceæ*. A very large group of globular, strongly ribbed, and strongly spiny cacti, growing from the United States to South America, particularly abundant in Mexico.

Sometimes these cacti become very short-cylindrical; occasionally the ribs are broken up into tubercles which resemble those of *Mammillaria*; and rarely spines are entirely wanting: the fls. usually appear just above the young spine-bearing areas, but sometimes they are farther removed, and occasionally they are in the axil of a tubercle; the ovary bears scales which are naked or woolly in the axils, and the fr. is either succulent or dry.—The genus is well developed within the U. S., about 40 species having been recognized, but its extreme northern limit is the southern borders of Colo., Utah, and Nev., apparently having spread from the great arid plateau regions of Mex. proper and Low. Calif. The genus extends throughout Mex. but is not found in Cent. Amer. It is well represented, however, in the drier regions of S. Amer. *Echinocactus* and *Mammillaria* are distinguished chiefly by the way in which the fls. are borne,—terminal on the tubercles in the former, and axillary to tubercles in the latter. In external appearance they are very similar. The genus *Astrophytum* is here included, although it seems to be very different from the typical forms of *Echinocactus* and should doubtless be kept distinct. It is impossible to identify with certainty all of the specific names found in trade catalogues, but the following synopsis con-

tains the greater part of them. In all cases the original descriptions have been consulted, and in some cases it is certain that a name originally applied to one form has been shifted to another. The following synopsis may be useful, therefore, in checking up the proper application of names, but it may thus leave some of the common species of the trade unaccounted for. No attempt is made to group the species according to relationships, but a more easily handled artificial arrangement, chiefly based upon spine characters, is used. It must be remembered that the species are exceedingly variable, especially under cult., and large allowance must be made for the characters given in the key and in the specific descriptions.

Unlike most globular forms of cacti, *echinocacti* do not readily produce offsets; consequently they must be propagated by seeds if one wishes to increase these plants in quantity. Seeds of *echinocactus*, and, in fact, most cacti, will germinate as freely as seeds of other plants, provided they have been allowed to ripen properly before gathering and carefully dried afterward. The months of May and June have been found to be by far the most favorable for germination. Seeds of *echinocactus* will then germinate in five or six days, while during the winter months it takes almost as many weeks. *Opuntias* will germinate in even less than six days; they germinate most readily of all the *Cactaceæ*, and grow the fastest afterward, while *mammillarias* are the slowest to germinate and grow the slowest afterward.—The seeds should be sown in well-drained 4-inch pots in a finely sifted mixture of one part leaf-mold, one part loam and one part charcoal dust and silver sand. The surface should be made very smooth, and the seeds pressed lightly into the soil with the bottom of a flower-pot and then covered with about  $\frac{3}{8}$  inch of fine silver sand. This allows the seedlings to push through readily and prevents the soil from crusting on the surface of the pots, as they usually have to stay in their seedling pots at least one year. The pots should be placed in a greenhouse where they will receive plenty of light but not the direct sunlight, for, although cacti are natives of desert regions, the seedlings will roast if exposed to full sunlight under glass. For the first winter, at least, the seedlings should be kept in a temperature of not less than 60° and carefully looked over every day to ascertain the condition of the soil, for, although they should be kept on the dry side, they must never be allowed to become quite dry during the seedling stage. When about a year old they may be transplanted to shallow pans not more than 6 inches in diameter, and prepared with the same mixture as for seedling pots. These pans will be found better than small pots, because the soil may be kept more evenly moist and the seedlings do better in consequence. When grown from 2 to 3 inches in diameter, seedling *echinocacti* may be transferred to pots, using only sizes just large enough to accommodate them, as they make but few roots. Pot them in a mixture of two parts fibrous loam, one part leaf-mold and one part pounded brick and silver sand. During the spring and summer months, established plants may be given a liberal supply of water, but must be studiously watered during the fall and winter months.—During the winter they should be given a light position in a dry greenhouse, with a night temperature of 45° to 50°, and a rise of 10° by day. For the summer, they may be either kept in an airy greenhouse or placed in some convenient position outside, plunging the pots in the soil or in some light non-conducting material. Some of the species will begin to blossom in May and others at intervals during the summer. The flowers vary considerably in size, and embrace a good range of color, from white to deep yellow, and from faintest purple to deep rose. They do not readily produce seed (in New England, at least) unless artificially pollinated.—Like most of the cactus family, the more cylindrical species

will readily unite when grafted upon other kinds, not only in the same genus, but in other genera of Cactaceæ, and for weak-growing species it may often be an advantage to graft upon some stronger-growing species. *Cleistocactus Baumannii* (or *C. colubrinus*) makes an excellent stock to graft upon, choosing stock plants of reasonable size and height. The system known as "wedge-grafting" is perhaps best for the purpose, and the early spring months, or just as the growing season is about to begin, is the best time for grafting.—If plants of echinocactus can be kept in a healthy condition, they are not much troubled with insect pests; mealy-bug is their worst enemy and should be removed at once with a clean mucilage brush.—The following varieties have been found to be among the most easily grown: *E. capricornis*, *E. coptonogonus*, *E. cornigerus*, *E. Grusonii*, *E. horizontalionius*, *E. longihamatus*, *E. myriostigma*, *E. setispinus*, *E. texensis*, and *E. Wislizenii*. (E. J. Canning.)

## A. Spines, or some of them, hooked (Nos. I-10).

## B. Central spine solitary.

1. *Wrightii*, Coulter (*E. uncinatus* var. *Wrightii*, Engelm.). Oval, 3-6 in. high, 2-3½ in. diam.: radial spines 8, arranged as in *E. uncinatus*; central spine solitary, angled, flexuous and hooked, elongated (2-6 in.), erect, straw-color, with dark tip: fls. 1-1½ in. long, dark purple. Texas and N. Mex.

## BB. Central spines 4.

## c. Some or all of the spines annulate.

2. *cylindraceus*, Engelm. Globose to ovate or ovate-cylindrical, simple or branching at base, becoming as much as 3 ft. high and 1 ft. diam.: ribs 13 in younger specimens, 20-27 in older ones, obtuse and tuberculate: spines stout, compressed, more or less curved, reddish; radials about 12, with 3-5 additional slender ones at upper edge of areole, 1-2 in. long, the lowest stouter and shorter and much hooked; centrals 4, very stout and 4-angled, about 2 in. long and ½-⅓ in. broad, the uppermost broadest and almost straight and erect, the lowest decurved: fls. yellow. S. W. U. S. and Low. Calif.

3. *longihamatus*, Gal. Subglobose or at length ovate, becoming 1-2 ft. high: ribs 13-17, often oblique, broad, obtuse, tuberculate-interrupted: spines robust, purplish or variegated when young, at

length ashy; radials 8-11, spreading, straight or curved or flexuous, the upper and lower ones 1-3 in. long, the laterals 2-4 in.; centrals 4, angled, the upper ones turned upward, straight or curved or twisted, the lower one stouter, elongated (3-8 in.), flexuous and more or less hooked: fls. yellow, tinged with red, 2½-3½ in. long. Texas and Mex.

4. *Wislizenii*, Engelm. At first globose, then ovate to cylindrical, 1½-4 ft. high: ribs 21-25 (13 in small specimens), acute and oblique, more or less tuberculate: radial spines ¾-2 in. long, the 3 upper and 3-5 lower ones stiff, straight or curved, annulate, red (in old specimens the 3 stout upper radials move toward the center and become surrounded by the upper bristly ones), the 12-20 laterals (sometimes additional shorter ones above) bristly, elongated, flexuous, horizontally spreading, yellowish white; centrals 4, stout, angled, and red, 1½-3½ in. long, the 3 upper straight, the lower one longest (sometimes as much as 4-5 in.), very robust (flat and channeled above), hooked downward: fls. yellow or sometimes red, 2-2¾ in. long. From S. Utah to N. Mex. and Low. Calif.

## cc. None of the spines annulate.

5. *brevihamatus*, Engelm. Globose-ovate, very dark green: ribs 13, deeply tuberculate-interrupted, the tubercles with a woolly groove extending to the base: radial spines mostly 12, terete, straight, white or yellowish, with dusky tips, ½-1 in. long, the upper longer; central spines 4 (rarely 1 or 2 additional ones), flattened, white with black tips, the 2 lateral ones divergent upward, straight or a little recurved, 1-2 in. long, the uppermost one weaker, the lower stoutest and darkest, porrect or deflexed, hooked downward, ¾-1 in. long: fls. funnelform, rose-color, 1-1½ in. long. S. W. Texas and New Mex.

6. *sinuatus*, Dietr. (*E. Treculianus*, Labour.). Globose, 4-8 in. diam., bright green: ribs 13, oblique, acute, tuberculate-interrupted, the tubercles short-grooved: radial spines 8-12, setiform and flexible, the 3 upper and 3 lower purplish brown and straightish (the lower ones sometimes more or less hooked), ½-1 in. long, the 2-6 laterals more slender, longer (1-1½ in.), often flattened, puberulent and whitish, sometimes flexuous or hooked; central spines 4, puberulent, yellowish (or purplish variegated), the 3 upper ones slender, flattened or subangled, erect and generally straight (rarely hooked). 1½-2 in. long, the lowest one much stouter, flattened or even channeled, straw-color, flexuous, more or less hooked (sometimes straight), 2-4 in.

long: fls. yellow, 2-3 in. long. Texas, Ariz. and N. Mex.

7. *uncinatus*, Gal. Glaucous, globose to oblong: ribs 13, obtuse, tuberculate-interrupted: radial spines 7 or 8, 1-2 in. long, the upper 4 or 5 straw-color, straight, flattened, the lower 3 purplish, terete and hooked; centrals 4, the upper 3 rather stout and straight, about 1 in. long, the lowest one very long, flattened, hooked at apex: fls. brownish purple. N. Mex.

8. *Whipplei*, Engelm. Fig. 1371. Globose-ovate, 3-5 in. high, 2-4 in. diam.: ribs 13-15 (often oblique), compressed and tuberculately interrupted: radia-

1371. *Echinocactus Whipplei*. (×½)

spines usually 7, compressed, straight or slightly recurved,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long, lower ones shorter than the others, all white excepting the two darker lowest laterals; central spines 4, widely divergent, the uppermost one flattened, straight and white, 1–1½ in. long, turned upward in the plane of the radials (completing the circle of radials), the others a little shorter, quadrangular-compressed, dark brown or black, becoming reddish and finally ashy, the 2 laterals straight, the lowest one stouter and sharply hooked downward: fl. greenish red. N. Ariz. Fig. 1371 is adapted from the Pacific Railroad Report.

BBB. *Central spines 5 to 8.*

9. **cornigerus**, DC. Globose or depressed-globose, 10–16 in. diam.: ribs about 21, very acute and wavy (not tuberculately interrupted): radial spines 6–10, white and comparatively slender, or wanting; centrals red and very robust, angular-compressed, with long, sharp, horny tips, the upper 3 erect-spreading, 1–1½ in. long, the lower 2 weaker and declined, the central one longer, more rigid and keeled, very broad ( $\frac{1}{2}$ – $\frac{1}{3}$  in.) and hooked downward: fls. purple, 1–1½ in. long. Mex.

10. **polyancistrus**, Engelm. & Bigel. Ovate or at length subcylindric, becoming 4–10 in. high and 3–4 in. diam.: ribs 13–17, obtuse, tuberculately interrupted: radial spines 20 or more, compressed and white, the uppermost wanting, the 4 upper ones broader and longer (1–2 in.) and dusky-tipped, the laterals shorter ( $\frac{1}{2}$ –1 in.), the lowest very short ( $\frac{1}{2}$  in.) and subsetaceous; central spines of several forms, the uppermost one (rarely a second similar but smaller one above or beside it) compressed-quadrangular, elongated (3–5 in.), white with dusky tip, curved upward, the other 5–10 teretish or subangled, bright purple-brown; upper ones long (2–4 in.) and mostly straight, the others gradually shortening (to about 1 in.) downward and sharply hooked: fls. red or yellow, 2–2½ in. long and wide. Nev. and S. E. Calif.

AA. *Spines not hooked (Nos. 11–48).*

B. *Central spines none or indistinct.*

11. **Monvillii**, Lem. Stout, globose and bright green: ribs 15–17, tuberculate, broadest toward the base, undulate: tubercles somewhat hexagonal, strongly dilated below: radial spines 9–12, the lower ones somewhat longer, very stout, spreading, yellowish translucent, reddish at base; central wanting: fls. varying from white to yellow and red. Paraguay.

12. **Pfeifferi**, Zucc. Oblong-globose, becoming 1–2 ft. high and 1 ft. diam.: ribs 11–13, compressed and somewhat acute: spines 6, about equal, rigid, straight, divergent or erect, pale transparent yellow with a brownish base; very rarely a solitary central spine. Mex.

13. **coptonogonus**, Lem., var. **major**, Salm-Dyck. Depressed, from a large indurated naked napiform base, 2–4 in. across the top: ribs 10–15, acute from a broad base, more or less transversely interrupted and sinuous: spines 3, annulate, very stout and erect from deeply sunken areoles, reddish when young, becoming ashy gray; upper spine stoutest, erect and straight, or slightly curved upward, flattened and keeled, and occasionally twisted,  $1\frac{1}{2}$ – $2\frac{1}{4}$  in. long; the 2 laterals erect-divergent, straight or slightly curved, terete above and somewhat quadrangular below, 1–1½ in. long; all from an abruptly enlarged base: fls. said to be small and white, with purplish median lines. Mex.

14. **multicostatus**, Hildmann. Depressed-globose: ribs very numerous, 90–120, compressed into thin plates which run vertically or are twisted in every direction: spines exceedingly variable, in some cases wanting entirely, in others 3 or 4, short, rigid, and translucent yellow; in others more numerous, larger, and often flattish; in still other cases very long and flat, inter-

lacing all over the plant; no centrals: fls. white, with a broad purple stripe. Mex.

15. **capricornis**, A. Dietr. Globose: ribs about 11, broad, spotted all over with white dots: clusters of spines distant, usually seen only near the apex; spines 5–10, long and flexuous; centrals not distinct: fls. large, yellow. Mex.

16. **rinconensis**, Poselg. Cylindrical, covered with ivory-white spines which are tipped with crimson: spines 3, with no centrals: fls. large, purple-crimson, darker at base. N. Mex.

17. **phyllacanthus**, Mart. From globose to cylindrical, with depressed vertex, simple or proliferous,  $2\frac{1}{2}$ – $3\frac{1}{2}$  in. broad: ribs 40–55 (sometimes as few as 30), very much crowded and compressed, thin, acute, very wavy, continuous or somewhat interrupted: radial spines 5 (sometimes 6 or 7), straight and spreading, the 2 lowest ones white, rigid,  $\frac{1}{6}$ – $\frac{1}{4}$  in. long, half as long as the 2 darker, angled, larger laterals, the uppermost spine thin and broad, channeled above, faintly annulate, flexible, grayish pink,  $\frac{3}{5}$ –1 in. long; central spines none: fls. small, dirty white. Mex.

BB. *Central spine solitary (sometimes 2–4 in E. crispatus, E. helophorus, and E. setispinus, or wanting in E. lophothele).*

c. *Sts. with less than 13 ribs.*

18. **leucacanthus**, Zucc. Somewhat clavate-cylindrical, pale; ribs 8–10, thick, obtuse, strongly tuberculate, the areoles with strong wool: radial spines 7 or 8, similar, straight, finely pubescent, at first yellowish, at length white; central spine solitary, more or less erect, rarely wanting: fls. light yellow. Mex.

19. **ornatus**, DC. (*E. Mirbellii*, Lem.). Subglobose: ribs 8, broad, compressed, vertical, thickly covered with close-set white woolly spots, making the whole plant almost white: radial spines 7, straight, stout, yellowish or becoming gray; central spine solitary. Mex.

20. **ingens**, Zucc. (*E. Visnaga*, Hook.). Very large (sometimes as much as 10 ft. high and as much in circumference), globose or oblong, purplish toward the top: ribs 8, obtuse, tuberculate: areoles large, distant, with very copious yellowish wool: radial spines 8 or more; central spine solitary; all the spines shaded yellow and red or brownish, straight, rigid, and interwoven: fls. bright yellow, about 3 in. broad. Mex.

21. **horizontalis**, Lem. Glaucescous, depressed-globose or at length ovate or even cylindric with age, 2–8 in. high,  $2\frac{1}{2}$ –4 in. diam.: ribs 8–10 (fewer in very young specimens), often spirally arranged, the tubercles scarcely distinct by inconspicuous transverse grooves: spines 6–9, stout, compressed, reddish (at length ashy), recurved or sometimes almost straight, nearly equal,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. long (sometimes long and slender and almost terete, sometimes short, stout and broad); radials 5–8, upper ones weaker, lowest wanting; a single stouter decurved central (sometimes wanting): fls. pale rose-purple,  $2\frac{1}{2}$  in. long or more. New Mex. and N. Mex.

cc. *Sts. with 13–27 ribs.*

22. **electracanthus**, Lem. Globose or thick cylindrical, becoming 2 ft. high and 1 ft. diam.: ribs about 15: radial spines about 8, equal, rigid, spreading, yellowish, about 1 in. long; the central one solitary, red at base: fls. clear yellow. Mex.

23. **Echidne**, DC. (*E. Vanderzypii*, Lem.). Depressed-globose, 5–7 in. diam., 3–4 in. high: ribs 13, acute: radial spines 7, broad, rigid, spreading, yellowish, 1 in. or more long; central spine solitary and scarcely longer than the others: fls. bright yellow, 1 in. or more long. Mex.

24. **texensis**, Hopf. Mostly depressed (sometimes globose), 8–12 in. diam., 4–6 in. high, simple: ribs

mostly 21 (sometimes 27, and in smaller specimens 13 or 14) and undulate: spines stout and fasciculate, reddish, compressed; the exterior 6 or 7 radiant, straightish or curved, unequal,  $\frac{1}{2}$ – $\frac{3}{4}$  in. long in some cases,  $1\frac{1}{2}$ –2 in. in others, much shorter than the solitary and stout recurved central, which is sometimes  $\frac{1}{2}$ – $\frac{1}{4}$  in. broad: fls. about  $\frac{1}{2}$  in. long, parti-colored (scarlet and orange below to white above). Texas and N. E. Mex.

25. *rectispinus*, Brit. & Rose. Fig. 1372. Globose, at length cylindrical: ribs 13–21, obtuse and strongly tuberculate: radial spines 7–9, very unequal, the 3 upper ones 4–5 in. long, the lower  $1\frac{1}{2}$ –3 in. long and paler; the central very long (12–13 in.), straight or slightly decurved: fls. about  $1\frac{1}{2}$  in. long, pinkish; ovary bearing a few ovate, scarious, naked scales. Low. Calif.

26. *Emoryi*, Engelm. Becoming large, globular to cylindrical plants, 1–4 ft. high: ribs 13–21, obtuse: radial spines 7–9, nearly equal, stout, 1–2 in. long; central spine single, porrect, hooked: fls. red, tipped with yellow: fr. 1–2 in. long, covered with thin bracts. S. Ariz. and N. Sonora.

27. *recurvus*, Link & Otto. Subglobose and very stout: ribs about 15, covered with broad, dark red spines, the radials spreading, the central one recurved and very stout. Mex.

28. *setispinus*, Engelm. Subglobose, 2–3½ in. diam.: ribs 13, more or less oblique, often undulate or somewhat interrupted: radial spines 14–16, setiform and flexible,  $\frac{3}{8}$ – $\frac{1}{2}$  in. long, the uppermost (the longest) and lowest ones yellowish brown, the laterals white; central spines 1–3, setiform and flexuous, dark, 1–1½ in. long: fls. funnelform,  $1\frac{1}{2}$ –3 in. long, yellow, scarlet within. Texas and N. Mex.

29. *helóphorus*, Lem. Depressed globose, light green with purple-red veins: ribs about 20, compressed, obtuse: radial spines 9–12, very stout and porrect; central spines 1–4, stronger and annulate; all the spines pearl-gray. Mex.

ccc. *Sts. with 30 or more ribs.*

30. *obvallatus*, DC. Obovate-globose, depressed: ribs very numerous, vertical: spines most abundant towards the apex, unequal, spreading, stout, whitish; the 3 upper radials and solitary central strong, the others (especially the lowest) small: fls. purple, with whitish margin. Mex.—The name was suggested by the appearance of the terminal cluster of fls. surrounded by a fortification of strong spines.

31. *crispatus*, DC. (*E. drrigens*, Link) Globose, 5 in. or more high: ribs 30–60, compressed and sharp, more or less undulate-cripsed: spines 7–11, widely spreading, more or less flattened, the upper larger and brown at tip, the lower shorter and white, or all of them brown: fls. purple, or white with purple stripes. Mex.

1372. *Echinocactus rectispinus*. No. 25.

cccc. *Sts. tuberculate, as in Mammillaria.*

32. *hexædróphorus*, Lem. More or less globular, dark gray: ribs deeply tuberculate, giving the appearance of a mammillaria, with hexagonal tubercles: radial spines 6 or 7, radiating like a star; central spine solitary, erect, longer; all the spines annulate, reddish brown: fls. white, tinted with rose. Mex.

33. *lopothèle*, Salm-Dyck. Globose, strongly tuberculate, after the manner of *Mammillaria*: tubercles quadrangular, bearing clusters of 5–10, more or less porrect, long, rigid, and equal spines; central solitary or wanting: fls. white or yellowish. Mex.

BBB. *Central spines 4 (2 or 3 in E. Sileri and sometimes 3 in E. Scopa).*

c. *Ribs less than 13.*

34. *robustus*, Otto. Clavate and stout: ribs about 8, compressed, vertical: radial spines about 14, the upper ones slender, the lowest 3 stronger; central spines 4, 4-angled at base, transversely striate, the lowest one largest; all the spines purple-red,  $1\frac{1}{2}$ –3 in. long: fls. golden yellow. Mex.

35. *Ottónis*, Link & Otto. Depressed-globose or ovate, 3–4 in. high: ribs 10–12, obtuse: radial spines 10–18, slender, yellowish, more or less straight and spreading, about  $\frac{1}{2}$  in. long; central spines 4, dusky red, stronger, the uppermost very short, the 2 laterals horizontal, the lowest longest (1 in.) and deflexed: fls. lemon-yellow, becoming 2–3 in. diam. Mex.

36. *bicolor*, Gal. Globose-ovate, stout,  $1\frac{1}{2}$ –4 in. diam., sometimes becoming 8 in. high: ribs 8, oblique and obtuse, compressed, tuberculate-interrupted: lower radials and centrals variegated red and white; radials 9–17, spreading and recurved, slender and rather rigid, the lowest one  $\frac{1}{2}$ –1 in. long, the laterals 1–2 in. long and about equaling the 2–4 flat flexuous ashy upper ones; centrals 4, flat and flexuous,  $1\frac{1}{2}$ –3 in. long, the uppermost thin and not longer than the erect and rigid laterals, the lowest very stout, porrect and very long: fls. funnelform, bright purple, 2–3 in. long. N. Mex.

cc. *Ribs 13–27.*

37. *orthacánthus*, Link & Otto (*E. flavovirens*, Scheidw.). Globose, yellowish green: ribs 12 or 13, vertical, acute: radial spines 14, unequal, straight and spreading; central spines 4, stronger, the lowest the largest; all the spines rigid, annulate, and grayish white. Mex.

38. *intertéxtus*, Engelm. Ovate-globose, 1–4 in. high: ribs 13, acute, somewhat oblique, tuberculate-interrupted, the tubercles with a woolly groove: spines short and rigid, reddish from a whitish base and with dusky tips; radial 16–25, closely appressed and interwoven, the upper 5–9 setaceous and white, straight  $\frac{1}{2}$ – $\frac{1}{2}$  in. long, the laterals more rigid and a little longer, the lowest stout and short, a little recurved; centrals 4, the 3 upper ones turned upward and exceeding the radials and interwoven with them, the lower one very short, stout and porrect: fls. about 1 in. long and wide, purplish. Texas and N. Mex.

39. *Órcuttii*, Engelm. Cylindrical, 2–3½ ft. high, 1 ft. diam., single or in clusters up to 18 or more, not rarely decumbent: ribs 18–22, often oblique: spines extremely variable, angled to flat,  $\frac{1}{4}$ –3 in. wide; radials 11–13, unequal, lowest and several laterals thinnest; centrals 4: fls. about 2 in. long, deep crimson in center, bordered by light greenish yellow. Low. Calif.

40. *Jónhsonii*, Parry. Oval, 4–6 in. high: ribs 17–21, low, rounded, tuberculately interrupted, close set, often oblique, densely covered with stoutish reddish gray spines: radial spines 10–14,  $\frac{3}{8}$ – $1\frac{1}{2}$  in. long, the upper longest; centrals 4, stouter, recurved, about  $1\frac{1}{2}$  in. long: fls. 2–2½ in. long and wide, from deep red to pink. Utah, Nev., Calif.

41. *polycéphalus*, Engelm. & Bigel. Globose (6–10 in. diam.) to ovate (10–16 in. high, 5–10 in. diam.) and cylindrical (reaching 24–28 in. high and about 10 in. diam.), profusely branched at base: ribs 13–21 (occasionally 10): spines 8–15, very stout and compressed, more or less recurved and reddish; radials 4–11, comparatively slender (the uppermost the most slender), 1–2 in. long; the 4 centrals much stouter and longer ( $1\frac{1}{2}$ – $2\frac{1}{2}$  in.), very unequal, the uppermost one usually broadest and curved upward, the lowest one usually the longest and decurved: fls. yellow. Utah to Calif.

42. *viridescens*, Nutt. Globose or depressed, simple or branching at base, 4–12 in. high, 6–10 in. diam.: ribs 13–21 (fewer when young), compressed and scarcely tuberculate: spines more or less curved and sometimes twisted, reddish below, shading into greenish or yellowish above; radials 9–20,  $\frac{2}{5}$ – $\frac{1}{2}$  in. long, the lowest shortest, robust, and decurved; centrals 4, cruciate, much stouter, compressed and 4-angled,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. long, the lowest broadest, longest and straightest: fls. yellowish green, about  $1\frac{1}{2}$  in. long. S. Calif.—*E. limitus*, Engelm., is closely related to this species and is thought by some to be identical with it.

43. *Lecónteii*, Engelm. Resembles *E. Wislizenii*, but often somewhat taller (sometimes becoming 8 ft. high and 2 ft. diam.), usually more slender, and at last clavate from a slender base: ribs somewhat more interrupted and more obtuse: lower central spine more flattened and broader, curved (rather than hooked) or twisted, usually not at all hooked, sometimes as much as 6 in. long: fls. rather smaller. From the Great Basin to Mex. and Low. Calif.

44. *Sileri*, Engelm. Globose: ribs 13, prominent, densely crowded, with short rhombic-angled tubercles: radial spines 11–13, white; centrals 3, black, with pale base,  $\frac{3}{8}$  in. long, the upper one slightly longer: fls. scarcely 1 in. long, straw-colored.

45. *Grüsonii*, Hildmann. Globose, completely covered by a mass of almost transparent golden spines, which give the plant the appearance of a ball of gold: centrals 4, curved: fls. red and yellow. Mountains of Mex.—From illustrations it is evident that the radial spines are somewhat numerous and widely spreading, and that the centrals are prominent and more or less deflexed.

1373. *Echinocactus Palmeri*. No. 46.

46. *Pálmeri*, Rose (*E. saltillénsis*, Poselg.). Fig. 1373. Very stout, globose: ribs 15–19, compressed, dark green: spines very prominent, 5–7 in a cluster, stout and porrect, sometimes becoming 5 in. long; centrals 4. Mex.—Schumann makes this a variety of *E. ingens*.

ccc. Ribs 30 or more.

47. *Scôpa*, Link & Otto. More or less cylindrical, 1 ft. or more high, 2–4 in. diam., at length branching above: ribs 30–36, nearly vertical, tuberculate: radial spines 30–40, setaceous, white; central spines 3 or 4, purple, erect; sometimes all the spines are white: fls. yellow. Brazil.—The species is exceedingly plastic in form, branching variously or passing into the cristate condition.

1374. *Echinocactus myriostigma* No. 50.

BBBB. Central spines 5–10.

48. *pildsus*, Gal. Globose, 6–18 in. high: ribs 13–18, compressed, little if at all interrupted: radial spines represented by 3 slender ones at the lowest part of the pulvillus or wanting; centrals 6, very stout, at first purplish, becoming pale yellow, the 3 upper ones erect, the 3 lower recurved-spreading: fls. unknown. N. Mex.

AAA. Spines entirely wanting.

49. *turbinifórmis*, Pfeiff. Depressed-globose, grayish green, with 12–14 spirally ascending ribs, cut into regular rhomboidal tubercles; tubercles flat, with a depressed pulvillus, entirely naked excepting a few small setaceous spines upon the younger ones: fls. white, with a purplish base. Mex.—The depressed and spineless body, with its surface regularly cut in spiral series of low, flat tubercles, gives the plant a very characteristic appearance.

50. *myriostigma*, Salm-Dyck (*Astróphytum myriostigma*, Lem.). Fig. 1374. Depressed-globose, 5 in. diam.: ribs 5 or 6, very broad, covered with numerous somewhat pilose white spots, and with deep obtuse sinuses: spines none: fls. large, pale yellow. Mex.

*E. chrysanthus* (*E. chrysacanthus*)= (?).—*E. Drageanus*= (?).—*E. Lewinii*= Lophophora.—*E. micromeris*= Mammillaria.—*E. Poselgerianus*, A. Dietz.= Mammillaria Scheerii.—*E. Simpsonii*= *Pediocactus*.—*E. trifurcatus*= (?).—*E. Williamsii*= Lophophora.

JOHN M. COULTER.  
J. N. ROSE.†

**ECHINOCEREUS** (*spiny Cereus*). *Cactaceæ*. Condensed globular, cylindrical or prostrate cacti of the United States and Mexico.

Stems single or caespitose, sometimes forming large clusters of 200–300 sts., distinctly ribbed, usually low in stature, or, if elongated, sprawling or creeping, generally very spiny: fls. yellow, purplish or scarlet, with rather a short funnel-

shaped tube; fl.-tube and ovary covered with clusters of spines; stigma-lobes always green. This genus has commonly been merged into *Cereus*, although it seems to be quite distinct.

Most of the species of *Echinocereus* are unsuited for greenhouse purposes, for when brought under glass they survive only for a few years. The very large flowers of some species make them very attractive while in bloom.

A. *Sts. covered with long weak bristles or hairs, and resembling a small plant of Cephalocereus senilis.*

1. *De Lætii*, Gürke. Low and caespitose, 6–10 in. high: ribs 17–20: radial spines numerous; central spines 4 or 5, intermixed with long, hair-like bristles entirely hiding the plant: fls. small, rose-colored. Mex.—This species has been secured in great quantities by European dealers. It closely simulates a small *Cephalocereus senilis*, but has very different fls. and fr.

AA. *Sts. variously covered with spines, but not like the above (Nos. 2–27).*

B. *The sts. weak and trailing, at least becoming prostrate.*

c. *Ribs nearly continuous.*

2. *Scheeri*, Lem. (*Cereus Scheeri*, Salm-Dyck). Branching freely from the base of the st. and forming dense clusters: branches upright or ascending, about 8 in. long by 1 in. diam., slightly tapering toward the apex, dark green: ribs 8–9, straight or sometimes inclined to spiral, separated above by sharp grooves which become flattened toward the base, low arched: areoles little more than  $\frac{1}{4}$  in. apart, round, yellowish white: radial spines 7–9, spreading, needle-like, the under pair the longest, about  $\frac{1}{4}$ – $\frac{3}{8}$  in. long, white with yellowish bases; centrals 3, the lower the longest, about  $\frac{3}{8}$  in., red with brown bases; later all the spines become gray: fls. red, from the upper part of the st., about 5 in. long; ovary and tube bracteate and furnished with abundance of wool and spines. Mex.

CC. *Ribs divided into tubercles.*

D. *Central spines, when present, short: flowering areoles bearing cobwebby wool.*

3. *procumbens*, Lem. (*Cereus procumbens*, Engelm.). Branching from the lower part of the st. and so forming clusters: branches procumbent or ascending, angled, at the base tapering into cylindrical,  $1\frac{1}{2}$ –5 in. long by  $\frac{1}{2}$ – $\frac{3}{4}$  in. diam.: ribs mostly 5, rarely 4, straight or spiral, on the upper portion of the branch almost divided into tubercles: areoles  $\frac{1}{4}$ – $\frac{1}{2}$  in. apart, round, sparingly white curly-woolly, soon naked: radial spines 4–6, subulate, stiff, straight, sharp, in young growth brownish, then white, at the base often yellowish and the tip brownish, horizontally spreading, the upper the longest, reaching  $\frac{1}{4}$  in. length; central solitary or absent on the lower areoles, somewhat stronger,  $\frac{3}{8}$ – $\frac{5}{8}$  in. long, darker: fls. lateral, from just below the crown, 3–4 in. long, carmine-red to violet, with white or yellowish throat: fr. ellipsoidal, green,  $\frac{5}{8}$  in. long. Mex.

DD. *Central spines slender: flowering areoles with short wool.*

E. *Length of central spine  $\frac{3}{4}$  in.*

4. *Berlandieri*, Lem. (*Cereus Berlandieri*, Engelm.). Sts. prostrate, richly branching, forming dense clus-

ters, the branches upright or ascending, 2–3 in. long or longer, by  $\frac{1}{2}$ – $\frac{3}{4}$  in. diam., light or dark green, and in young growth often purplish: ribs 5–6, broken up into as many straight or spiral rows of tubercles; tubercles conical, pointed: areoles  $\frac{3}{8}$ – $\frac{5}{8}$  in. apart, round, white-woolly, soon naked: radial spines 6–8, stiff bristle-form, thin, horizontally spreading, white, about  $\frac{3}{8}$  in. long, the upper one sometimes light brown and somewhat stronger; central solitary, yellowish brown, sometimes reaching  $\frac{3}{4}$  in. length: fls. from the upper lateral areoles, 2–3 in. long, red to light pink: fr. ovoid, green, bristly. S. Texas and N. Mex.

EE. *Length of central spine 1 in. or more.*

5. *Blankii*, Palmer (*Cereus Blankii*, Poselg.). Branching freely from the base and thus forming clusters: sts. columnar, tapering above, about 6 in. long by 1 in. diam., dark green: ribs 5–6 (rarely 7), straight, almost divided into tubercles: areoles about  $\frac{3}{8}$  in. apart, round, white curly-woolly, later naked: radial spines mostly 8, horizontally spreading, the under pair the longest, reaching about  $\frac{3}{8}$  in. length, all stiff, straight, thin, white or the upper ones carmine-red when young, later reddish brown; central solitary, porrect, later deflexed, 1–1 $\frac{1}{4}$  in. long, white or brownish, black when young: fls. from near the crown, 2 $\frac{1}{2}$ –3 in. long, purple-red to violet. Mex. R.H. 1865: 90.

BB. *The sts. usually short and stout, usually erect.*

c. *Fls. rather small, scarlet.*

D. *Ribs 5–7.*

E. *Spines terete.*

6. *paucispinus*, Rümpl. (*Cereus paucispinus*, Engelm.). Clustered in irregular bunches: sts. cylindrical to ovoid, 4–7 in. high by  $1\frac{1}{4}$ –3 in. diam.: ribs 5–7, undulate: areoles  $\frac{3}{8}$ – $\frac{5}{8}$  in. apart, round, white-woolly, later naked: radial spines 3–6, spreading, subulate, straight or curved, round, bulbous at the base, the lowest one longest, reaching  $\frac{3}{4}$  in., light-colored, the upper ones reaching to about  $\frac{1}{2}$  in., reddish or brownish; central solitary or none, reaching about 1 $\frac{1}{2}$  in. length, somewhat angled, brown-black, porrect or upright; later all the spines blackish: fls. 2 in. or more long, dark scarlet to yellowish. Texas and Colo.

Var. *gonacanthus*, K. Sch. (*E. gonacanthus*, Lem. *Cereus gonacanthus*, Engelm. & Bigel.). Radial spines 8, very large, angled and sometimes twisted, the upper strongest, reaching nearly 3 in. length, light or dark yellow with brown tips; central always present, deeply grooved, often flattened, 3 in. or more long. Colo.

EE. *Spines angled.*

7. *triglochidiatus*, K. Sch. (*E. triglochidiatus*, Engelm. *Cereus triglochidiatus*, Engelm.). Radial spines usually 3, sometimes as many as 6, strong, angled, base bulbous, straight or curved, about 1 in. long, soon ash-gray. Texas and New Mex.

DD. *Ribs 9–11.*

E. *Axils of fl.-bracts filled with long cobwebby hairs.*

8. *polyacanthus*, Engelm. (*Cereus polyacanthus*, Engelm.). Sts. clustered, forming thick masses, cylindrical to ellipsoidal: ribs 9–13: radial spines 8–12, robust, subulate, stiff and sharp, under one the longest, nearly 1 in., upper ones scarcely  $\frac{1}{2}$  in., white to reddish gray with dark tips; centrals 3–4, bulbous base, stronger, about the length of the radials or the lowest sometimes reaching 2 in., horn-colored; later all the spines become gray: fls. lateral, about 1 $\frac{3}{4}$ –2 $\frac{1}{4}$  in. long, dark scarlet to blood-red: fr. spherical, about 1 in. long. greenish red, spiny. Texas to N. Mex.

EE. *Axils of fl.-bracts bearing short wool.*

F. *Central spines always solitary: sts. 6–8 in. high. Mex.*

9. *ácifer*, Lem. (*Cereus ácifer*, Otto). Sts. thickly clustered, 6–8 in. high by  $1\frac{1}{2}$ –2 in. diam., becoming

gray and corky with age: ribs 9-11, usually 10: radial spines usually 9, spreading, under pair longest, about  $\frac{1}{2}$  in., in young growth white, later horn-colored to gray, the upper ones brownish; central solitary, straight, porrect, at first ruby-red, later brown, 1 in. long: fls. lateral, 2 in. and more long, clear scarlet-red, with a yellow throat and sometimes a carmine border. N. Mex.

FF. Central spines 1-4: sts. 2-4 in. high. New Mex. and Colo.

10. **coccineus**, Engelm. (*E. phæniceus*, Lem. *Cereus phæniceus*, Engelm.). Sts. irregularly clustered, ellipsoidal to short-cylindrical, 2-4 in. high by  $1\frac{1}{2}$ - $2\frac{1}{4}$  in. diam.: ribs 8-11, straight: spines bristle-form, straight, round; radials 8-12, white,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long, upper ones shortest; centrals 1-4, stouter, white to yellow or brown, with bulbous base: fls. from upper lateral areoles scarlet-red, with the corolla-throat yellow. Colo. to Ariz.

Var. **conoideus**, Engelm. (*E. conoideus*, Rümpl. *Cereus conoideus*, Engelm.). Central spine long and robust: fls. large, red. S. Calif. and N. W. Mex.

cc. Fls. never scarlet, usually crimson or purplish, sometimes yellow.

d. Spines more or less pectinate: ribs 12 or more.

e. Areoles short, spines orbicular.

f. Color of spines white.

11. **longisetus**, Lem. (*Cereus longisetus*, Engelm.). Sts. clustered, cylindrical, covered with long, dirty white spines, about 8 in. high by 2 in. diam., light green: ribs 11-14, straight, undulate: radial spines 18-20, straight, compressed, base thickened, subulate, flexuose, usually horizontally spreading, interlocking with adjacent clusters, the lower laterals the longest, reaching  $\frac{3}{8}$  in. long, the upper more bristle-like and the shortest, all white; centrals 5-7, longer, reaching  $2\frac{1}{2}$  in., stronger, the upper ones scarcely longer than the longest radials; all are bulbous at the base; the 3 lower ones the longest and deflexed, spreading and sometimes curved: fls. red. Mex.

FF. Color of spines white and brown.

12. **chloranthus**, Rümpl. (*Cereus chloranthus*, Engelm.) Fig. 1375. Sts. in small clusters, cylindrical, slightly tapering above, 4-9 in. high by  $2\frac{1}{2}$  in. diam.: ribs 13-18, straight or rarely spiral: radial spines 12-20, horizontally spreading and appressed, sharp, the shortest one about  $\frac{3}{8}$  in. long and white, the lower laterals a little longer and have purple tips; centrals 3-5, or in young plants absent, bulbous at the base, the upper ones shortest, about the length of the radials, and darker colored, with purplish tips, the lower ones stouter, about 1 in. long, deflexed, white; frequently all the spines are white: fls. lateral, little more than 1 in. long; ovary and tube white bristly; petals green: fr. ellipsoidal, about  $\frac{1}{2}$  in. long, spiny. Texas and New Mex.

1375. *Echinocereus chloranthus*.

shortest one about  $\frac{3}{8}$  in. long and white, the lower laterals a little longer and have purple tips; centrals 3-5, or in young plants absent, bulbous at the base, the upper ones shortest, about the length of the radials, and darker colored, with purplish tips, the lower ones stouter, about 1 in. long, deflexed, white; frequently all the spines are white: fls. lateral, little more than 1 in. long; ovary and tube white bristly; petals green: fr. ellipsoidal, about  $\frac{1}{2}$  in. long, spiny. Texas and New Mex.

EE. Areoles more or less elongated.

F. Color of fls. greenish or yellow.

G. Fls. greenish.

13. **viridiflorus**, Engelm. (*Cereus viridiflorus*, Engelm.). Sts. solitary or only in age forming small, loose clusters, cylindrical or elongated, ellipsoidal, 3-7 in. high by 1-2 in. diam: ribs 13: radial spines 12-18, horizontally radiate, pectinate, straight or somewhat curved, subulate, the lower laterals the longest, about  $\frac{1}{2}$  in., translucent ruby-red, the others white; centrals usually absent, rarely 1, strong, about  $\frac{3}{4}$  in. long, curved upward, red with brown point: fls. lateral, from just below the crown, broad funnelform, little more than 1 in. long; ovary and tube spiny; corolla green, with a broad darker olive-green to pink stripe down the middle of each petal: fr. ellipsoidal, about  $\frac{1}{2}$  in. long, greenish. Wyo. and Kans. to Texas and New Mex.

GG. Fls. yellow.

H. Ribs 15-21: central spines unequal.

14. **dasyacanthus**, Engelm. (*Cereus dasyacanthus*, Engelm.). Sts. solitary or sometimes forming open clusters, ellipsoidal to short-cylindrical ribs 15-21, straight or sometimes slightly spiral, obtuse: radial spines 20-30, straight or sometimes slightly curved, subulate, stiff, sharp, pectinate, white with red or brown tips, later gray, the laterals longest,  $\frac{1}{2}$ -1 in., the upper ones shortest, about  $\frac{3}{8}$  in., those of one cluster interlocking with those of the adjacent clusters; centrals 3-8, the lower one longest, white with colored tips, mostly with bulbous bases: fls. from near the crown of the st. large,  $2\frac{1}{2}$ -3 in. long; ovary and short tube covered with white, reddish tipped stiff bristles; corolla yellow: fr. 1- $1\frac{1}{2}$  in. long, ellipsoidal, spiny, green to reddish. Texas.

HH. Ribs 15 or 16: central spines very short, equal.

15. **ctenoides**, Lem. (*Cereus ctenoides*, Engelm.). Sts. solitary or rarely branching, cylindrical to elongated ovoid, reaching a height of 6 in. and a diam. of  $2\frac{1}{2}$  in.: ribs 15-16, usually straight: radial spines 13-22, horizontally radiate, pectinate, subulate, bases bulbous and laterally compressed, stiff, straight or often slightly curved, the laterals longest and about  $\frac{3}{8}$  in., the upper ones very short, white or sometimes with brownish tips; centrals 2-3 or rarely 4, superposed, coarser, bulbous at the base, short and conical to  $\frac{1}{4}$  in. long, reddish; later all the spines are gray: fls. lateral, from near the crown,  $2\frac{1}{2}$ -3 in. long; ovary and short tube white bristly; corolla yellow, with greenish throat. Texas. and N. Mex.—This species is very rare in cult.

FF. Color of fls. purple.

G. The spines irregularly pectinate.

16. **Rötteri**, Rümpl. (*Cereus Rötteri*, Engelm.). Loosely open clustered: sts. upright, 4-6 in. high, 2-3 in. diam., cylindrical or ovoid: ribs 10-13, straight: radial spines 8-15, subulate, thickened at the base, stiff, sharp, straight or slightly curved, the laterals longest, about  $\frac{1}{2}$  in., the upper ones shortest, reddish with darker tips; centrals 2-5, stouter, bulbous at base,  $\frac{1}{4}$ - $\frac{3}{8}$  in. long, the lower ones the longest; later all the spines are gray: fls. lateral, from near the crown,  $2\frac{1}{2}$ -3 in. long, purple-red to violet: fr. short ellipsoidal, spiny, green,  $\frac{3}{4}$  in. long. Texas to Ariz. and N. Mex.

GG. The spines regularly pectinate.

H. Tube of fl. and spines of ovary slender and weak, the surrounding hairs long and cobwebby.

17. **cæspitosus**, K. Sch. (*Cereus cæspitosus*, Engelm.). Radials 20-30, curved, clear white or with rose-red tips; centrals absent, or 1-2 very short ones. Okla., Texas and Mex.

HH. Tube of fl. and spines of ovary short and stout, the surrounding hairs short.

I. Central spines several.

18. *pectinatus*, Engelm. (*Cereus pectinatus*, Engelm.). Clustered sts. cylindrical or ovoid, reaching a height of 10 in. by 3 in. diam.: ribs 13-23, straight: radial spines 16-30, pectinate, horizontally spreading and appressed, straight or curved, the laterals longest, round, hardly  $\frac{3}{8}$  in. long; central usually absent, or as many as 5, which are short, conical and superposed, white, with tips and bases variously colored with pink, yellow or brown; later all become gray: fls. lateral, from near the crown,  $2\frac{1}{2}$ -4 in. long; ovary tuberculate and spiny, light to dark rose-red or rarely white: fr. globose, spiny, green to reddish green. Mex.

Var. *adustus*, K. Sch. (*Cereus adustus*, Engelm.). Like the type, but with black-brown to chestnut-brown spines. Mex.

Var. *rufispinus*, K. Sch. Of more robust growth: radial spines curved, red. Mex.

II. Central spines none.

19. *rigidissimus*, Engelm. (*Cereus candicans*, Hort. *C. rigidissimus*, Hort.). RAINBOW CACTUS. Fig. 1376. Sts. comparatively shorter and thicker: radial spines 16-20, coarser and stiffer, straight or very little curved; base thickened, white, yellow or red to brown, these colors commonly arranged in alternating bands around the plant, the spines of adjacent clusters interlocking; centrals absent. Ariz. and N. Mex.

DD. Spines not pectinate.

E. Ribs 10 or fewer.

F. Fls. crimson.

20. *mojavensis*, Rümpl. (*Cereus mojavensis*, Engelm. & Bigel.). Sts. clustered, ovoid, reaching 3 in. height by 2 in. diam.: ribs 8-12, conspicuously undulate: radial spines 5-8, the lowest pair the longest, reaching about  $2\frac{1}{4}$  in. long; all are white with brown tips, subulate, straight or curved, strongly bulbous at the base; central solitary, or sometimes absent, stronger and somewhat longer and darker colored; later all the spines become gray: fls. 2-3 in. long, deep carmine: fr. ellipsoidal, about 1 in. long. Deserts of Ariz., Nev. and Calif.

FF. Fls. purple-violet.

G. The spines dark, often of several colors.

H. Central spine 1.

21. *Fendleri*, Rümpl. (*Cereus Fendleri*, Engelm.). Irregularly clustered: st. cylindrical or rarely ovoid or even globose, sparingly branching, 3-7 in. high by  $1\frac{3}{4}$ - $2\frac{1}{2}$  in. diam.: ribs 9-12, straight or slightly spiral, undulate: radial spines 7-10, subulate, straight or curved, the lowest or the 2 lower laterals the longest, about 1 in., stronger, quadrangular, white; the 2 next higher brownish; the upper ones round, white and much shorter; all are bulbous at the base; central solitary (or in old plants 3-4), very strongly thickened at the base, round, black, sometimes with a lighter colored tip, curved upward, reaching a length of  $1\frac{3}{4}$  in.: fls. lateral, from near the crown, 2- $3\frac{1}{2}$  in. long, dark carmine-red to purple and violet: fr. ellipsoidal, spiny, green to purple-red, about 1 in. long. Colo., Utah and south to N. Mex. B.M. 6533.

HH. Central spines several.

22. *Engelmannii*, Lem. (*Cereus Engelmannii*, Parry). Sts. clustered, cylindrical to ovoid, 4-10 in. high,  $1\frac{3}{4}$ - $2\frac{1}{2}$  in. diam., light green: ribs 11-13, undulate: radial spines 11-13, somewhat angled, stiff, sharp, straight or somewhat curved, horizontally spreading, the lowest or lower laterals the longest, about  $\frac{1}{2}$  in., the upper ones the shortest, whitish with brown tips; centrals 4, stiff, straight, angled, stout, the lowest one deflexed, white

to dark-colored, reaching a length of  $2\frac{1}{2}$  in., the upper ones about half as long, spreading, brown: fls. lateral, from just below the crown,  $1\frac{3}{4}$ - $2\frac{1}{2}$  in. long, purple-red: fr. ovoid, green to purple-red, spiny, later naked, about 1 in. diam.; pulp purple-red. Calif. to Utah and south into Mex.

Var. *chrysocentrus*, Engelm. & Bigel. The 3 upper centrals golden yellow, the lowest white. Mojave Desert, Calif.

Var. *variegatus*, Engelm. & Bigel. The 3 upper centrals curved, horn-colored and mottled with black. Utah, Nev. and Calif.

GG. The spines usually white or straw-colored.

H. Central spines somewhat curved.

23. *dubius*, Rümpl.

(*Cereus dubius*, Engelm.). Tolerably thickly clustered: sts. branching at the base, cylindrical or elongated ellipsoidal,  $4\frac{1}{2}$ -7 in. high by  $1\frac{1}{2}$ - $2\frac{1}{4}$  in. diam.: ribs 7-9, undulate: areoles  $\frac{3}{8}$ - $\frac{5}{8}$  in. apart, round, covered with short curly white wool, later naked: radials 5-8, subulate, horizon-

1376. *Echinocereus rigidissimus*.

tally spreading, stiff, round or faintly angled, the lower ones usually the longest, about 1 in. long, the upper ones about half as long, or sometimes absent, transparent white; centrals 1-4, stronger and longer, bulbous at the base, straight or curved, reaches  $2\frac{1}{2}$  in. length, the lowest one longest, straight, porrect or deflexed, the upper ones spreading: fls. lateral, 2 in. long, rose-red to violet: fr. spherical, greenish to purple-red, covered with bundles of deciduous spines. Texas and N. Mex.

HH. Central spines straight.

I. Sts. erect, with the spines pale at base.

24. *enneacanthus*, Engelm. (*Cereus enneacanthus*, Engelm.). Freely branching at the base of the st. and thus forming thick, irregular clusters: branches ascending, usually 3-5 in. long by  $1\frac{1}{2}$ -2 in. diam., green or sometimes reddish: ribs 8-10, straight, often divided by transverse grooves into more or less conspicuous tubercles: areoles  $\frac{3}{8}$ - $\frac{5}{8}$  in. apart, round, white curly-woolly, soon naked: radial spines 7-12 (mostly 8), horizontally spreading, needle-form, straight, stiff, translucent white, base bulbous, the under one longest, reaching about  $\frac{1}{2}$  in., the upper one very short; central solitary, or seldom with 2 additional upper ones, straight, porrect or deflexed, round or angled, whitish to straw-yellow or darker,  $\frac{3}{8}$ - $1\frac{1}{2}$  in. long; later all the spines are gray: fls. lateral, from near the crown or lower,  $1\frac{3}{4}$ - $2\frac{1}{2}$  in. long, red to purplish: fr. spherical, green to red, spiny,  $\frac{3}{4}$ -1 in. long. Texas and N. Mex.

II. Sts. spreading and flabby, with the spines red at base.

25. *Mérkeri*, Hildmann. Sts. at first upright, columnar, later reclining and by branching at the base forming clusters, in new growth bright green, later gray to gray-brown and corky: ribs 5-9, undulate to more or less tuberculate: areoles  $\frac{3}{4}$  in. and more apart, round, white velvety, later naked: radial spines 6-9, the upper ones the longest, reaching  $1\frac{1}{4}$  in. length, somewhat confluent with the centrals, subulate, spreading, straight; centrals 1-2, stronger, reaching a length of 2 in.; all the spines are white, nearly transparent, with red-tinted bulbous base. N. Mex.

EE. *Ribs 11 or 13.*F. *Plants in small clusters: central spines sometimes solitary.*

26. **conglomeratus**, Forst. Sts. clustered, columnar, somewhat tapering above, reaching a height of 1 ft. and 2 in. diam., light green: ribs 12–13, strongly undulate, tubercled above: radial spines 9–10, glossy, spreading, the lower pair the longest, base yellow; centrals 1–4, the lowest straight, porrect, reaching a length of  $1\frac{1}{2}$  in. and more, somewhat stronger than the rest. N. Mex.

FF. *Plants often 200 in a single mound: centrals never single.*

27. **stramineus**, Rümpl. (*Cereus stramineus*, Engelm.). Clustered in thick, irregular bunches: sts. ovoid to cylindrical, 4–8 in. long,  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. diam.: ribs 11–13: radial spines 7–10 (usually 8), horizontally radiate, straight or slightly curved, subulate, sharp, round or the long lower ones angled, transparent white, tolerably equal in length, about  $\frac{1}{2}$ – $\frac{3}{4}$  in. or the lower ones sometimes longer and reaching a length of  $1\frac{1}{2}$  in.; centrals 3–4, much longer, stronger, twisted, angled, taw-yellow to brownish, when young reddish transparent, the upper ones shortest and spreading upward, the lower ones porrect or depressed: fls. lateral,  $2\frac{1}{2}$ – $3\frac{1}{2}$  in. long, bright purple-red or deep dark red, to scarlet: fr. ellipsoidal, about  $1\frac{1}{2}$  in. long, covered with numerous spines, purple-red. Texas to Ariz. and N. Mex.

Horticultural names are: *E. paucispina*, no doubt a mutilation of *paucispinus*.—*E. polycephalus*.—*E. sanguineus*.—*E. Schlenkeri*.—*E. Scheeri* (?).—*E. tuberosus*, Rümpl.=Wilcoxia.—*E. Uehri*.—*E. Uspendkii*.

C. H. THOMPSON.  
J. N. ROSE.†

**ECHINÓCHLOA** (Greek, *echinos*, a hedgehog, *chloa*, grass). *Gramineæ*. Annual grasses with narrow inflorescence of several thick spikes. Sometimes grown for grain and forage, but scarcely horticultural subjects.

Spikelets as in *Panicum*; glumes hispid-spiny, mucronate, the sterile lemma more or less awned.—Species about 12, in the warm regions of both hemispheres. Regarded by many botanists as a section of *Panicum*. *E. Crusgalli*, Beauv., barnyard grass, is a common weed in cult. soil. The spikelets are usually long-awned, the panicle 4–10 in. long, green or purple. Dept. Agric., Div. Agrost. 7:82.

**frumentacea**, Link (*Panicum frumentaceum*, Roxbg.). JAPANESE BARNYARD MILLET. Closely allied to *E. Crusgalli*, but differing in the compact, somewhat incurved, appressed spikes, of nearly awnless spikelets: culms 1–4 ft., erect.—Cult. in S. E. Asia for the seed which is used for food. Occasionally cult. in U. S. for forage. Sometimes known as “billion-dollar grass.”

A. S. HITCHCOCK.

**ECHINOCYSTIS** (Greek, *hedgehog* and *bladder*; from the prickly fruit). Syn. *Micrampelis*. *Curcubitaceæ*. WILD CUCUMBER. WILD BALSAM-APPLE. A profuse native annual vine which is a favorite for home arbors; the other species not generally cultivated, except perhaps the perennial-rooted *megarrhiza*.

Most of the species are annual herbs, with branched tendrils and palmately lobed or angled lvs.: fls. small, white or greenish, dioecious, the campanulate calyx 5–6-lobed and the corolla deeply 5–6-parted; stamens in staminate fls. 3; ovary 2-celled, with 2 ovules in each: fr. fleshy or dry, more or less inflated and papery, opening at the summit; seeds flattened, more or less rough.—The species are about 25, in the warmer parts of the western hemisphere, about 10 of them in the W. U. S., and 1 in the eastern states. The eastern species (*E. lobata*) is one of the quickest-growing of all vines, and is therefore useful in hiding unsightly objects while the slower-growing shrubbery is getting a start. Cogniaux, in DC. Mon. Phan. vol. 3, 1881, makes three sections of this genus, and this plant the sole

representative of the second section, or true *Echinocystis*, because its juicy fr. bursts irregularly at the top, and contains 2 cells, each with 2 flattish seeds. The *Megarrhiza* group (kept distinct by some) is distinguished by its thick perennial root, large turgid seeds and hypogeal germination.

**lobata**, Torr. & Gray. Lvs. wider than long, deeply 5-lobed, slightly emarginate at the base: tendrils 3–4-branched: staminate fls. small, in many-fl. panicles longer than the lvs.; calyx glabrous: fr. egg-shaped, sparsely covered with prickles. New Bruns. and Ont. to Mont. and Texas, growing in rich soil along rivers and in low places. A.G. 14:161. R.H. 1895, p. 9. G.C. III. 22:271. G.W. 10, p. 499.—Sometimes becomes a weed.

**fabacea**, Naudin (*Megarrhiza californica*, Torr.), is sometimes grown in fine collections and botanic gardens. It is a tendril-climber, reaching 20–30 ft. in its native haunts: lvs. deeply 5–7-lobed: fls. monœcious, greenish white, the corolla rotate: fr. densely spinose, globose or ovoid, 2 in. long; seed obovoid, nearly or about 1 in. long and half or more as broad, margined by a narrow groove or dark line. S. Calif.—Odd in germination (see Gray, Amer. Journ. Sci. 1877, and Structural Botany, p. 21).

L. H. B.†

**ECHINÓPANAX** (Greek, *hedgehog* and *panax*, referring to the prickly nature of the plant). *Arabiaceæ*. Ornamental shrub, but rarely grown; very handsome on account of the large foliage and scarlet fruits.

Deciduous, prickly throughout: lvs. alternate, long-petioled, palmately 5–7-lobed, with serrate lobes, without stipules: fls. greenish white, in umbels forming terminal panicles; calyx-teeth indistinct; petals 5, valvate; stamens 5, with filiform filaments; styles 2, connate at the base: fr. a compressed drupe.—One species, Pacific N. Amer., Alaska to Calif., and Japan.

This is a strikingly handsome shrub with its large bright green palmately lobed leaves and scarlet fruits late in summer. Little known in cultivation; it will succeed best in moist and cool places and in partial shade. Propagation is by seeds and by suckers and probably also by root-cuttings.

**hórridum**, Deene. & Planch. (*Fatsia hórridum*, Benth. & Hook. *Panax hórridum*, Smith). Shrub, to 12 ft.: sts. densely prickly: lvs. roundish-cordate, prickly on both sides, pubescent below, 5–7-lobed, lobes incisely lobulate and sharply serrate, 6–12 in. long; infl. tomentose: fr. scarlet,  $\frac{1}{3}$  in. long. July, Aug.; fr. Aug., Sept.

ALFRED REHDER.

**ECHINOPS** (Greek, *like a hedgehog*; alluding to the spiny involucre scales). *Compositæ*. GLOBE THISTLE. Coarse thistle-like plants, with blue or whitish flowers in globose masses, sometimes used in the wild garden.

More or less white-woolly herbs: lvs. alternate, sometimes entire, usually pinnate-dentate or twice or thrice pinnatisect, the lobes and teeth prickly: fls. in globes; the structure of one of the globes is very odd; each fl. in the globe has a little involucre of its own, and the whole globe has one all-embracing involucre; fls. perfect and fertile (or sterile by abortion), corolla regular and no ray-fls.; pappus of many short scales forming a crown: achene elongate, 4-angled or nearly terete, usually villous.—About 60 species, from Spain and Portugal to India and Abyssinia.

Globe thistles are coarse-growing plants of the easiest culture, and are suitable for naturalizing in wild gardens and shrubberies. An English gardener with an eye for the picturesque (W. Goldring) recommends massing them against a background of *Bocconia cordata*, or with such boldly contrasting yellow- or white-flowered plants as *Helianthus rigidum* or *Helianthus multiflorus*. The best species is *E. ruthenicus* (form of *E. Ritro*). A few scattered individuals of each species are not so effective as a condensed group of one kind.

*E. ruthenicus* flowers in midsummer and for several weeks thereafter. The silvery white stems and handsomely cut prickly foliage of globe thistles are interesting features. They make excellent companions for the blue-stemmed eryngiums. All these plants are attractive to bees, especially *E. exaltatus*, which has considerable fame as a bee-plant. Globe thistles are sometimes used abroad for perpetual or dry bouquets.

A. Lvs. not pubescent nor setulose above but sometimes roughish above.

**Ritro**, Linn. (*E. Vitro*, Hort.). Tall thistle-like plant, with pinnate-lobed lvs., which (like the sts.) are tomentose beneath, the lobes lanceolate or linear and cut, but not spiny: involucre scales setiform, the inner ones much shorter: fls. blue, very variable. G.M. 46:69. R.H. 1890, p. 524. G. 31:611. Var. *tenuifolius*, DC. (*E. ruthenicus*, Hort.), has the lower lvs. more narrowly cut, more or less spine-tipped. Gn. 45:174.—Perennials of S. Eu., growing 2-3 ft. high. They bloom all summer. Lvs. sometimes loosely webby above.

**Tournefortii**, Ledeb. (*E. Tournefortiana*, Hort.). Three to 4 ft., the sts. branched and velvety: lvs. rough above, white-hairy below, much divided into 5 linear segms., spiny: heads "silver-gray" (bluish), the involucre bracts free, bristly. E. Medit. region. Sept. B.M. 8217. R.H. 1906, p. 523.—Suitable for dry places.

AA. Lvs. pubescent or setulose above.

B. Plant perennial.

**sphaerocephalus**, Linn. Tall (5-7 ft.): lvs. pinnatifid, viscose-pubescent above, tomentose below, the teeth of the broad lobes yellow-spined: fls. white or bluish, the involucre bracts subulate-acuminate, free. S. Eu. B.R. 356 (as *E. paniculatus*).

**humilis**, Bieb. Three to 4 ft.: lvs. very hairy on both surfaces, webby above, those of the st. essentially entire, the radical lvs. sinuate-lyrate, almost unarmed; st.-lvs. with spiny tips: heads large, blue, the involucre bracts all distinct and free. Sept. Asia.

**bannaticus**, Rochel. Lvs. hairy-pubescent above, tomentose beneath (as also the sts.), the lower ones deeply pinnately parted, the upper pinnatifid, spiny: fls. blue. Hungary. R.H. 1858, p. 519.

BB. Plant biennial.

**exaltatus**, Schrad. Tall, the st. nearly simple and glandulose-pilose, the lvs. pinnatifid, scarcely spiny: fls. blue. Russia. B.M. 2457 (as *E. strictus*, Fisch.).—Distinguished by its simple, erect st. The garden *E. commutatus* may be the same as this.

*E. nivālis*, Hort., is a trade name that is unknown in botanical literature.

N. TAYLOR.†

**ECHINÓPSIS** (Greek, *hedgehog-like*). *Cactaceæ*. SEA-URCHIN CACTUS. South American small condensed cacti.

Stems spherical to ellipsoidal or rarely columnar: ribs prominent and usually sharp-angled: fls. usually long trumpet-shaped; ovary and tube covered with linear-lanceolate, cuspidate bracts which become longer toward the outer end of the tube, where they pass gradually into the outer petals, in their axils bearing long, silky, wavy hairs and usually a few rather rigid bristles.—This is a well-marked genus of about 18 species, although by some authors combined with *Cereus*. Cult. as for *Echinocactus*; see also *Succulents*.

Only a few species of *Echinopsis* are grown in this country, although they are more easily grown and

propagated than most of the United States species of cacti. The genus is well adapted for use as window plants.

A. Ribs of st. divided into more or less evident tubercles.

**Péntlandii**, Salm-Dyck (*Echinocactus Péntlandii*, Hook.). St. simple, later branching, spherical or ellipsoidal, reaching 6 in. diam.: ribs 12-15, divided between the areoles into oblique compressed tubercles: radial spines 9-12, spreading, straight or slightly curved, yellowish brown, the upper the longest and strongest, reaching  $\frac{1}{2}$ -1 $\frac{1}{4}$  in.; central solitary, or seldom in pairs, porrect, curved, 1-1 $\frac{1}{2}$  in., rarely 3 in. long: fls. lateral, 2-2 $\frac{1}{2}$  in. long, yellow, orange, pink to scarlet-red: fr. spherical, green,  $\frac{3}{4}$  in. diam. Peru, Bolivia. B.M. 4124.—Probably not of this genus.

AA. Ribs of sts. not divided.

B. Fls. red or pink.

**múltiplex**, Zucc. Sts. at first rather clavate, later globose to ellipsoidal, abundantly branching, 6-12 in. diam. and the same in height, or rarely taller, light green to yellowish: ribs 12-14, straight, scarcely undulate: radial

spines about 10, subulate, straight, yellow to yellowish brown, with darker tips, reaching  $\frac{3}{4}$  in. length, very unequal, horizontally spreading; centrals mostly 4, of these the lowest is the longest, reaching  $1\frac{1}{2}$  in., somewhat porrect at first, later curved and deflexed, darker colored than the others: fls. rare, lateral, 11-15 in., rose-red. S. Brazil. B.M. 3789. Var. **cristata**, Hort. Sts. flat and spreading in growth, like an open fan or the fl.-stalk of the common garden cockscomb: spines reduced to fine, stiff bristles. This is merely a monstrosity of the species.

**oxygona**, Zucc. Sts. at first simple, nearly spherical or rarely clavate, becoming short columnar, reaching  $1\frac{1}{2}$  ft. height and 1 ft. diam., gray-green, darker above: ribs 13-15, straight or wavy at the base: radial spines 5-15, horizontally spreading, very unequal, reaching  $\frac{5}{8}$  in., subulate, obliquely upright; centrals 2-5, somewhat longer, straight, porrect or deflexed, dark horn-colored, with black tips: fls. commonly many together, lateral, reaching 13 in. length, pink to carmine-red, the inner petals lighter than the outer ones. S. Brazil.

**triumphans**, Jacobi. This is a hybrid between *E. Eyriesii* and *E. oxygona*, with pink double fls.

BB. Fls. white.

**Eyriesii**, Zucc. St. simple, commonly branching later, at first somewhat depressed, later short to rather tall columnar, reaching a height of 2 ft. and a diam. of 4-6 in., dark green: ribs 11-18, straight, undulate, with sharp-angled margins: radial spines about 10, scarcely more than  $\frac{1}{2}$  in. long, rigid, straight, slender conical, pointed, dark brown to black; centrals 4-8, but very little different from the radials: fls. lateral, 10-15 in. long, white: fr. small, ellipsoidal, about 1 in. long. S. Brazil, Uruguay and Argentina. B.M. 3411. B.R. 1707 (as *Echinocactus*).

**gemmata**, K. Sch. (*E. turbinata*, Zucc.). Fig. 1377. St. simple or sometimes branching, at first low spherical or short columnar, later more top-shaped, reaching 1 ft. height by 4-6 in. diam., dark green: ribs 13-14, rarely more, straight or sometimes slightly spiral with sharp or obtuse margins, which are but little or not at all undulate; central spines appear first, about 3-6 in number, very short, stiff, black; later the radials appear.

1377. *Echinopsis gemmata*.

about 10-14, longer, horizontally spreading, at first yellowish brown, later horn-colored: fls. lateral or from the upper areoles, 9-10 in. long, clear white, with a pale greenish midline in the petals. S. Brazil.

**tubiflora**, Zucc. (*E. Duvallii*, Hort. *E. Zuccarinii*, Pfeiff.). Sts. spherical to ellipsoidal, at first simple but later more or less branching, reaching 10 in. height by 8 in. diam., dark green: ribs 11-12, straight, with margins inconspicuously undulate: radial spines numerous, sometimes as many as 20, unequal, horizontally or obliquely spreading, yellowish white with brown tips, sometimes darker; centrals 3-4, the lowest the longest, reaching  $\frac{5}{8}$  in., later deflexed: fls. lateral, about 14 in. long, white with pale green midline in the petals. S. Brazil and Uruguay. B.M. 3627.

C. H. THOMPSON.

J. N. ROSE.†

**ECHINOSPÉRMUM**: *Lappula*.

**ECHINÓSTACHYS** (Greek, *spiny head*). *Bromeliaceae*. About a half-dozen species allied to *Æchmea* (with which some writers unite it), from S. Amer. Outer fl. parts bristly; petals broadly clawed, with 2 fringed scales or glands; ovary thick and fleshy, 3-seeded; spike cylindrical, thin, club-shaped: lvs. small, becoming darker after flowering. The species require hothouse conditions, as for *Æchmea* and related things. Three names have appeared in the American trade: *E. Hystrix*, Wittm., for which see *Æchmea Hystrix*. **E. Pineliána**, Wittm. (*Æ. Pineliána*, Baker). Two to 3 ft.: peduncle and bracts brilliant red: lvs. 12-18 in. long in a rosette, strap-shaped, deltoid at summit, spine-edged: spike dense, 2-3 in. long, spiny; petals golden yellow and becoming black-brown, the tips fringed and incurved. Brazil. B.M. 5321. **E. Van Houtteána**, Van Houtte (*Æ. Van Houtteána*, Mez. *Quesnelia Van Houtteána*, Morr.). Lvs. many, strong-spined, sometimes white-banded beneath: fls. white, blue-tipped, in a crowded spike, the bracts reddish at the summit and white-downy at the base: 1-2 ft. Brazil.

L. H. B.

**ECHITES** (Greek, *viper*; possibly from its poisonous milky juice or from its twining habit). *Apocynaceae*. Tropical American twining shrubs related to *Dipladenia*, and of similar culture.

The genus differs technically from *Dipladenia* in the 5-lobed disk and the glandular or 5-scaled calyx. Lvs. simple, opposite, penninerved: fls. usually showy, purple, red, yellow or white, in sub-cymose clusters; calyx small, 5-lobed, with many glands at the base inside or else 5 scales opposite the lobes; corolla salver-shaped, the throat usually contracted, the limb 5-lobed; stamens included, the filaments very short; stigma with an appendage in the form of a reversed cup or of 5 lobes.—Some 40 species, S. Fla. to Chile.

**Andrewsii**, Chapm. (*E. suberecta* Andr.). Lvs.  $1\frac{1}{2}$ -2 in. long, close together, oval or oblong, mucronate, acute or rounded at the base, margins revolute; peduncles axillary, 3-5-fl., shorter than the lvs.; fls. yellow, 2 in. long; corolla-tube much dilated above the insertion of the stamens, bell-shaped, scarcely longer than the lobes; anthers tapering into a long bristle-like awn. Sandy shores, S. Fla., W. Indies. B.M. 1064. P.M. 7:101.

**paludosa**, Vahl. Lvs. oblong, oval-oblong, or lanceolate-oblong, rounded toward the mucronate top: calyx-segms. glandular, devoid of an interior scale, oblong, mucronate-blunt, spreading; corolla-tube funnel-shaped above a cylindrical base; anthers oblong-lanceolate, acuminate, rounded-cordate at the base, hirsute on the back above. Mangrove swamps, S. Fla.

**umbellata**, Jacq. Lvs. ovate or ovate-roundish, mucronate: fls. greenish white; calyx-segms. glandular, devoid of an interior scale; corolla-tube cylindrical, enlarged below the middle, tapering again above; anthers rigid, tapering from a hastate base, glabrous. S. Fla., W. Indies.

WILHELM MILLER.

**ÉCHIUM** (from the Greek for a *viper*). *Boraginaceae*. **VIPER'S BUGLOSS**. Coarse, mostly rough herbs and shrubs, with spikes of blue, violet, red or white flowers, some of them grown in the open and others under glass.

Plant usually scabrous, hispid or canescent: lvs. alternate: fls. in unilateral, scirpoid, forked or simple spikes, with either small or foliaceous bracts; calyx with 5 narrow lobes; corolla tubular-trumpet-shaped, the throat oblique and dilated and without appendages; corolla-lobes 5, roundish and unequal, somewhat spreading or erect; stamens 5, inserted below middle of tube, unequal and exserted; ovary deeply 4-lobed; style filiform, 2-parted at top: fr. 4 nutlets.—Some 30-40 species, from the Canaries and Madeira (where they are specially important) to W. Asia. One species, *E. vulgare*, Linn., is a showy intro. biennial weed in fields and along roadsides, with blue or rose-tinted fls.; it is known as blue-weed and blue-devil. The shrubby species of Madeira and the Canaries are much confused, some of the names having been established on cult. material. This is particularly true of the forms passing as *E. candicans* and *E. fastuosum*, which are very unsatisfactorily determined (See Hooker, B.M. 6868). In those islands, the plants produce much forage and they persist from the goats in inaccessible places. (The portraits quoted below are cited under the names they bear.)

In rich soil echiums grow coarse and scarcely flower, and the flowers are never as richly colored as when the plants are more or less starved. Biennials seed freely, and the seed is sown as soon as gathered. *E. fastuosum* is said to be the handsomest of the shrubby kinds, grows 2 to 4 feet high, has long, pale green leaves covered with soft white hairs, and flowers of a peculiarly brilliant deep blue. Echiums are eminently suited for dry places, and need good drainage.

**candicans**, Linn. f. (*E. fastuosum*, Jacq. f., not Ait. *E. truncatum*, Hort.). Forms a bush several feet high, but flowers at 3 ft., the lvs. and sts. white-hairy; branches thick, leafy toward the tips: lvs. lanceolate, the upper ones smaller, crowded and narrower; panicles much looser than the spikes of *E. fastuosum*; fls. sessile, pale blue, the buds reddish purple, the pink stamens protruding. Madeira, Canaries, on mountains. B.M. 6868. B.R. 44. G.C. III. 51:368. G.M. 55:376.—The fls. are said sometimes to be streaked with white or all white.

**fastuosum**, Ait., not Jacq. This has darker blue fls. in a dense spike and perhaps less hoary foliage than *E. candicans*, the protruding filaments nearly white (said by some to be white in *E. candicans*). Coast, Canaries. R.H. 1876:10. Gn. 10:546. G.C. III. 33:328. G.W. 15, p. 356.—*E. fastuosum* has dark blue, 5-lobed fls. about  $\frac{1}{2}$  in. across, in spikes 6 in. long and 2 in. wide, perhaps as many as 200 fls. in a spike. Great masses of stamens are thrust out and add to the interest, and the young fl.-buds look like pink 5-pointed stars.

**simplex**, DC. Woody but biennial and not branched, 8-10 ft.: lvs. ample, oval-lanceolate; panicle very long, cylindrical, spike-like, the spikelets 2-fl., pedicelled; stigmas simple. R.H. 1912, p. 351. Gt. 51, p. 375. G.C. III. 53:20.

*E. Auberianum*, Hort., not Webb & Berth.—=*E. Bourgeanum*.—*E. Bourgeanum*, Webb. Stout and strict, 8-11 ft., the st. covered with long-linear drooping lvs.: fls. rose-colored, in a dense pyramidal spike. Mountains, Canaries. R.H. 1912, p. 440. G.C. III. 53:25. A striking plant.—*E. callithyrsum*, Webb. Woody or tree-like, robust, hispid-hairy: lvs. strongly nerved: calyx-segms. very unequal: fls. pale red: floral lvs. exceeding the different cymes of the thyrses. Canaries.—*E. formosum*, Pers.—=*Lobostemon*.—*E. Pininana*, Webb & Berth. Very large species, reaching 16 ft., with an abundance of stout spreading long-oblong lvs. G.C. III. 53:20.—*E. Wildpretii*, Pears. A tall soft-hairy biennial, with simple erect st. 2-3 ft.: lvs. sessile, narrowly linear-lanceolate, hairy: fls. pale red with long-exserted filaments, in a large terminal thyrsis: floral lvs. much exceeding the different cymes. Canaries. B.M. 7847. G.C. III. 38:5; 52:317. G.M. 53:111. Gn. 76, p. 363. G. 27:261.

WILHELM MILLER.  
L. H. B.†

EDELWEISS: *Leontopodium*.

**EDGEWORTHIA** (after M. P. Edgeworth, English botanist in East Indies, and his sister Maria). *Thymelæaceæ*. Ornamental woody subjects grown chiefly for their early yellow and fragrant flowers and for the handsome foliage.

Deciduous sparingly branched shrubs, with stout branches: lvs. alternate, entire, short-petioled, crowded at the end of the branches: fls. in dense, peduncled heads, axillary, on branches of the previous year, with or before the lvs., apetalous; calyx-tube cylindric, with 4 spreading lobes, densely villous outside; stamens 8, in 2 rows; style elongated, stigma cylindric: fr. a dry drupe.—Two species in Japan, China and Himalayas.

These plants are hardy only in warmer temperate regions, but do not stand hot and dry summers; they thrive in any good well-drained garden soil; if grown in pots, a sandy compost of peat and loam, with sufficient drainage given, will suit them. Propagation is by green-wood cuttings in spring under glass; also by seeds.

**papyrifera**, Zucc. (*E. chrysantha*, Lindl. *Daphne papyrifera*, Sieb.). Small shrub with thick branchlets: lvs. deciduous, membranous, elliptic-oblong to oblong-lanceolate, acute at the ends, at first clothed with silky hairs on both sides, later glabrous above, 3–5 in. long: heads of fls. dense, up to 2 in. across, on short axillary stalks; fls.  $\frac{3}{4}$  in. long, densely silky-hairy outside, fragrant, yellow, drying whitish; ovary pubescent only at the apex. April. Japan, China. B.R. 33:48. F.S. 3:289.—Cannot withstand the long dry summers.

**Gárdneri**, Meisn. Large shrub, with slender branchlets: lvs. persistent, of firmer texture: fls. with a more shaggy pubescence, drying black; ovary hairy throughout: otherwise very similar to the preceding species which is, by some botanists, considered not specifically distinct. April. Himalayas. B.M. 7180.

ALFRED REHDER.

**EDRAIÁNTHUS**: *Wahlenbergia*. By some kept distinct, to include about a dozen species. Spelled also *Hedreanthus*.

**EDUCATION, HORTICULTURAL.** In the United States and Canada, instruction in horticulture is part of the publicly maintained colleges of agriculture. In Canada, these colleges are provincial rather than national or established by the Dominion. The Canadian colleges of agriculture are: Nova Scotia and New Brunswick, Truro, N. S.; Quebec, Sainte Anne de Bellevue (only in part provincial); Ontario, Guelph; Manitoba, Winnipeg; Saskatchewan, Saskatoon; British Columbia, in plan at the university being established at Victoria.

In the United States, general horticultural education is mostly a part of a national system of professional and applied education of collegiate grade or name. There is a college of agriculture in every state in the Union, being part of a national system with coöperation and aid from the State. (For list, see *Experiment Stations*, p. 1195.)

There is little development, as yet, in North America of the training-school idea on either a private or a public basis, and relatively few institutions or establishments in which persons are trained for "gardening," as they are trained in the Old World. There is no recognized apprentice system for gardeners. The whole subject, therefore, needs to be considered quite by itself and not in comparison with systems or methods of education in horticulture in other and older countries; and it is necessary to understand something of the system of publicly endowed industrial education, of which instruction in horticulture is a part. The general nature of these institutions in both Canada and the United States may be understood from a brief discussion of the land-grant institutions in the latter country.

The public industrial education of the United States,

of college grade, is founded on the Land-Grant Act of 1862. By the terms of this great instrument, every state received from the federal government 30,000 acres of land for every representative that it had in Congress, the proceeds of which are to be used for "the endowment, support, and maintenance of at least one college where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, in such manner as the legislature of the states may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions in life." This endowment has been supplemented by subsequent direct federal appropriations, to further the objects for which the original grant was made. On this foundation, all the forty-eight states comprising the Union have established colleges of agriculture and the mechanic arts, about half of them separate institutions and about half of them connected with or part of state universities or other general institutions. The states themselves have supplemented and extended the proceeds of the land-grant. These and the Canadian colleges represent many types of organization and method. Their purpose is increasingly to train young men and women broadly by means of agricultural and country-life subjects. They are now exerting great influence in re-directing rural civilization. They are rapidly putting agricultural and rural subjects into educational form, and are demonstrating that such subjects may have training and even cultural value equal to that of historical subjects.

The agricultural colleges contain many departments, and horticulture is usually one of these departments, coördinate with the others. Some of these departments, aside from the work in the fundamental arts and sciences, are as follows: agricultural chemistry, agronomy, entomology, plant physiology, plant pathology, bacteriology, plant-breeding, soils, farm crops, farm management (the principles of business as applied to farming), horticulture, pomology, floriculture, forestry, animal husbandry, poultry husbandry, veterinary, dairy industry or dairy husbandry, home economics, farm mechanics and engineering, rural economy or agricultural economics, landscape gardening or landscape art, drawing, rural education, meteorology, and extension teaching. It will be seen, therefore, that horticulture is only one contributing part in an educational establishment for the teaching of agriculture in a broad way.

Aside from these publicly endowed or maintained institutions, there are a few other regular colleges that teach horticulture with other work, but they have not made great headway, although the subject may assert itself strongly in some of them in the future. There are two or three training-schools, one for women. More training-schools will be needed.

The students in agriculture in the colleges of agriculture number many thousands, in some cases 1,000 and more in one institution. They come from all walks and conditions of life, and from city and country alike. Some of them, of course, have strong inclinations for horticulture, and soon specialize in that subject. The full course of instruction is four years, following college entrance requirements, and the student at graduation receives a diploma carrying Bachelor of Science or a similar degree. In many of these institutions, post-graduate work in a variety of subjects is provided, leading to a master's degree or even to a doctor's degree.

The first institutions to develop horticulture as a separate subject appear to have been those in Michigan, under W. W. Tracy, Chas. W. Garfield and successors, Mr. Tracy having been instructor in horticulture as early as 1867; New York (1874) and in Ohio under

W. R. Lazenby; and in Iowa (1876) under J. L. Budd. The instruction by means of horticulture has now grown to great importance in many of the colleges, the staffs comprising, in some cases, as many as fifteen to thirty persons.

*The horticultural work in the colleges.*

We may now consider the horticultural teaching work of these colleges in more detail.

In the early days of such instruction, the horticulture was set over against the agriculture, and these two comprised the main applied groups. The breaking-out of the group of horticulture was really the beginning of the broadening of these institutions and of their more perfect articulation with the conditions before them.

Horticulture, as understood in these colleges, comprises fruit-growing, flower-growing, vegetable-gardening, together with the nursery and glasshouse subjects naturally associated with them. With the further differentiation of the curriculum, horticulture tends to be split or separated into its three main parts, with separate units or teacherships for each, but this division has not yet proceeded far in most of the institutions. If this division is ever carried to its conclusion, the name "horticulture" as an educational unit may pass out.

In the colleges, horticulture is regarded as a phase of the general agricultural field. For the most part, the student approaches the subject from the point of view of farming by means of fruits or vegetables or even of flowers. The strictly amateur phase is incidentally emphasized as a rule, and this undoubtedly is one of the weaknesses of the American horticultural instruction. The amateur attitude, however, will appear more markedly as the country develops and matures. The present attitude very well represents the development that America is now making, as expressed particularly in the great orchard interests. The gardeners, as a group, have had relatively little touch with these institutions in the way of dictating or even influencing their development. So far as institutions are concerned, the gardening phase of horticulture is well expressed where the great collections are, as at the Shaw or Missouri Botanical Gardens, Arnold Arboretum, New York Botanic Gardens, and others; and these institutions will also produce highly trained specialists in small numbers in related scientific lines.

The content of the work in the land-grant colleges varies greatly, depending, of course, on the constituency of the particular college as well as on the staff. Naturally, in the states in which horticultural interests are large, the work will express itself strongly in the college. Some of the courses in horticulture now offered in different colleges of agriculture may be displayed, showing how the subject is divided and what is considered to be the content of the instruction. These examples are chosen only to show the kind and the range of representative courses, and the writer makes no comment on them. Other courses might be chosen from the catalogues, but these are sufficient for illustration. In some cases, practically the same subject is entered twice: this represents the way in which the subject is phrased in different institutions. Some of the courses in landscape work that are given by departments of horticulture are also included.

*Elements of horticulture.*—Fruit-growing, vegetable-gardening and ornamental planting, with special reference to the farm home.

*Gardening.*—A personal and informal course for lovers of plants and gardens. The course consists of actual work with identification and growing plants, supplemented by conferences and informal discussions. Attention is given to garden literature and history, planning of grounds.

*Cultivated plants.*—The relationship and classification of certain economic and ornamental plants of the temperate zone; identification of species; examination of living plants and herbarium specimens.

*Evolution of horticultural plants.*—History, botanical classification, and geographical distribution of cultivated plants; modification under culture; theoretical causes and observed factors that influence variation, particularly food-supply, climate and cross-fertilization.

*Amateur floriculture.*—Window-gardening; growing of flowers on the home grounds; containers; potting soils; fertilizers; preparation and planting of flower-beds; propagation and culture of plants suitable for window and garden.

*Commercial floriculture.*—Studies in the propagation and culture of the leading florist crops. As facilities permit, students are assigned space in the greenhouses for practical experience in the growing of roses, carnations, chrysanthemums, violets, sweet peas, and other plants. Discussions on diseases, insects, botany, and the packing, handling, and marketing of cut-flowers and plants for retail and wholesale markets. Classes participate in a required excursion.

*Garden flowers.*—Designed to acquaint the student with garden plants and to give practical knowledge of the propagation and culture of the annuals, herbaceous perennials, bulbs, and shrubs used for cut-flowers or in ornamental planting.

*Greenhouse construction.*—The development of the modern greenhouse; types of houses, materials, and methods of construction, installation of heating systems, etc. Laboratory practice in erecting section of cypress and iron frame houses, and in planning and estimating the cost of commercial ranges for flower- and vegetable-production. The class participates in a required excursion.

*Greenhouse management.*—Studies of the principles and practice of propagation, soils, potting, shifting, watering, ventilation, and fumigation of plants cultivated by florists.

*Conservatory plants.*—A study of the culture and uses of tropical and subtropical plants grown in conservatories, including palms, ferns, begonias, orchids, etc.

*Floral design.*—A study of the principles of floral art. Practice in the arrangement of flowers in designs and bouquets, baskets, table decorations, interior decoration, etc.

*Greenhouse and garden practice.*—Designed to give the student practical knowledge of greenhouse work. Lectures and exercises in greenhouse management, propagation, composting soils, potting, watering, etc.

*Investigation in floriculture.*—The investigation of problems in the growing of cut-flowers, exotics, and garden flowers; hybridizing; study of varieties. Designed primarily for upper classmen and graduate students.

*Elements of landscape gardening.*—Reconnaissance surveys and mapping, with special reference to the methods used in landscape gardening; detailed study of selected designs of leading landscape gardeners; grade design, road design and field work.

*General design.*—Field notes; examination of completed works and those under construction; design of architectural details, planting plans, gardens, parks and private grounds; written reports of individual problems.

*Civic art.*—The principles and applications of modern civic art, including city design, city improvement, village improvement, and rural improvement.

*Trees and shrubs.*—Plant material important to landscape gardening; landscape value of each plant with respect to adaptability to the soil and situation and the use of the plant in design.

*Advanced landscape design.*—Real estate subdivisions and a complete set of plans, including a sketch plan, general plan, report, detailed study of architectural features, grading plans, planting plans, set of specifications, and estimate of cost.

*Landscape practice.*—Interpretation of topographic maps and their relation to landscape design; calculation of cut and fill; quantities of material; preparation of grading plans and working drawings.

*Exotics.*—Temporary decorative plants used in landscape gardening.

*Plant materials.*—This course aims to make the student familiar with the character of the trees, shrubs and herbaceous perennials used in ornamental work, and with the methods of propagating them.

*Decorative and bedding plants.*—Tropical and subtropical plants used in decorative work in the conservatory; tender plants used in outdoor bedding.

*Home vegetable-gardening.*—A study of vegetables and their production for home use. The planning and management of the garden, special crop requirements, factors influencing quality, and control of pests, will be considered. The laboratory work consists of actual practice in the garden. The starting of early plants in hotbeds and frames, intercropping and succession-cropping to secure largest yields from small areas, are studied. Each student assumes charge of his own plants and carries them through to the end of the term.

*Commercial vegetable-gardening.*—The principles of vegetable-growing as applied in commercial production; the scope of the industry and its opportunities; choice of location; equipment; management. The vegetable crops are considered singly, as to their adaptation, culture, special requirements, varieties, enemies, marketing, and profits. The laboratory work includes exercises in growing plants under glass and in the planting and care of early outdoor vegetables. Each student assumes full charge of his own plantings.

For students specializing or desiring a fuller knowledge of vegetable-gardening, another course is given, throughout the year. Advantage is taken of the opportunity for practice in harvesting, packing, and marketing fall crops. A two-days' excursion to two or three important vegetable-growing centers some time during May constitutes a part of the course. Each student gives a part of his time to a special problem, to be agreed on. Report on this problem is presented in typewritten form.

*Vegetable-forcing.*—Vegetable-growing under glass. Important

forcing crops. Laboratory consists of practical work in crop-production. Each student is assigned a plot in the greenhouse on which he grows vegetables to maturity, assuming full charge except in heating and ventilation. This is supplemented by descriptive studies.

**Systematic vegetable crops.**—Lectures and descriptive studies dealing with vegetable crops, their origin and botany. Special attention is given to varieties, and their adaptation to different cultural and market conditions. The important commercial types of the different vegetables are grown in the garden each year, and there is an abundance of first-hand material for the course.

**Advanced vegetable-gardening.**—The student's time is divided between advanced studies of vegetable crops and their culture and the study of a special problem to be agreed upon. An excursion to two or three important vegetable-growing centers constitutes a part of this course.

**Elementary pomology.**—A study of the methods of propagation and early care of commercial fruits, including the growing of seedlings, cuttings, and layers; the principles of budding, grafting, pruning, and planting; the soils, varieties, and planting plans for the orchard.

**Practical pomology.**—A study of the soils and varieties for the orchard; cultivation, cover-crops, fertilization, spraying, pruning, and thinning as practised in orchard management; the picking, grading, packing, storing, and marketing of fruit. This course considers the apple, pear, quince, cherry, plum, apricot, and peach.

**Systematic pomology.**—A study of the varieties of the different fruits and of nomenclature, with critical descriptions; special reference being given to relationships and classification.

**Bush-fruits.**—A lecture course which considers the grape, raspberry, blackberry, dewberry, currant, gooseberry, and strawberry. The topics discussed are: varieties, planting, culture, picking, grading, packing, and marketing.

**Small-fruits and grapes.**—The strawberry, raspberry, blackberry, dewberry, currant, gooseberry, grape. History; extent of cultivation; soil; location; fertilizers; propagation; planting; tillage; pruning; insect enemies; diseases; varieties; harvesting; marketing.

**Spraying of fruit trees.**—A study of the preparation and application of the spray mixtures used in orchard practice.

**Nuciculture.**—Lectures on the practical and systematic phases of nut-culture, with special reference to the cultivation and improvement of the forms native to the United States.

**Subtropical pomology.**—A study of citrus and other tropical fruits, with special reference to American conditions. Laboratory work in describing and judging the various fruits.

**Plant-propagation.**—Grafts; buds; layers; cuttings; seeds.

**Systematic pomology.**—A course designed primarily for graduates and students who are preparing to do experimental work. A study of the characters and botanical relationships of the fruits of the United States. Each student is required to collect and mount a number of varieties and species.

**Research in pomology.**—Original investigation of problems in pomology. A typewritten thesis is required.

The equipment for the horticultural work usually consists of classrooms, laboratories with tables and sometimes equipped for microscopic work, and herbaria; workrooms in which practice may be had in the mixing of soils, the compounding of spraying materials, the testing of machines, the study of vegetables and fruits, and the like; range of glasshouses; and a number of acres of land for gardens and orchards. Sometimes the orchard area amounts to fifty and more acres. In some colleges the plant-breeding is included with the horticulture; and in some of those that are least differentiated the plant pathology and economic entomology are also included, as also forestry. In the courses detailed above, all these subjects are excluded as horticulture, since they are likely to be handled in regular departments by themselves in numbers of different courses.

The subject of landscape architecture, or landscape gardening, has developed in the institutions in the United States from two sides. When it is an offshoot of colleges or departments of architecture, or when strongly dominated by architectural ideas, it is likely to be known as landscape architecture. In the agricultural colleges, however, the subject has developed mostly from the horticultural or gardening side, and has usually been called landscape gardening. As a part of the curriculum, landscape gardening is given more or less attention in nearly all the land-grant institutions. In three or four of them, however, the subject is now being given special and professional attention, as also at Harvard. Two institutions in this country give a post-graduate degree, Master of Landscape Architecture or Master of Landscape Design.

### Other forms of horticultural teaching.

The colleges of agriculture are engaged rather largely in extension work, the extension meaning all educational efforts prosecuted at the homes and on the farms of the people. The extension work is welfare work, and it is properly a necessary part of an institution that is maintained by the people for the service of the people. Some of this extension work is horticultural. It comprises tests and experiments in orchards, gardens, and greenhouses; coöperation with growers' associations; surveys of conditions and industries; the issuing of popular bulletins and other literature; lecture-courses, reading-courses, and much correspondence. See *Extension Teaching in Horticulture*, page 1199.

The experiment and research work of the institutions is also of course educational, but this effort is reserved for separate discussion. See *Experiment Stations*, page 1195.

In the public schools, there is now a strong sentiment for the introduction of agriculture. This pertains in all parts of the United States and Canada. This agricultural instruction will be organized eventually on the same basis as other instruction in the common schools. Agriculture will include a great variety of subjects, the horticultural affairs being given their due consideration. This will result in a gradual re-direction of the youthful mind toward horticultural and other rural pursuits.

The nature-study movement is widespread and established, and the material of the teaching is largely of plants. School-gardening is growing in popularity and importance. All these subjects are finding their way into normal schools and colleges, in some of which there is definite horticultural work for the training of teachers. Correspondence courses, the rural press, state departments of agriculture, and other agencies and enterprises are also forwarding horticultural education as a part of the general rural betterment.

In the United States and Canada, horticulture is largely a training for citizenship, on the basis of general collegiate education. The Americans have had a continental area to discover and to conquer; they are endeavoring to conquer it by many means, and the most fundamental means is by organizing all industry educationally. The horticultural subjects are important not only in themselves but in their personal appeal, and the organizing of horticultural knowledge into large plans and methods of human training is one of the best privileges of any people.

L. H. B.

EEL-GRASS: *Vallisneria spiralis*.

**EGGPLANT** (*Solanum Melongena*, Linn.). *Solanaceæ*. GUINEA SQUASH. AUBERGINE of the French. Strong perennial herb or sub-shrub, grown as a vegetable-garden annual for its large fruits, which are eaten cooked; requires a long warm season.

1378. Rotate corolla of eggplant; stamens connivent.

The eggplant is native of the tropics, probably from the East Indies, but its native land is not known. It is cultivated to a greater or less extent throughout the entire tropical regions. The first reports of its use as a vegetable come from India, hence the above assumption. In the United States it is cultivated as a vegetable as far north as

New York, but it usually grows to greater perfection in the southern states. It is much grown in Florida. The demands for it in the early months of the year have not been fully supplied. Its cultivation demands a specialist as much as either celery or tobacco, while the specialization must be in a different direction from that of either one of these. Nearly all of the fruit

that grows to proper size is edible, and there is no special demand for particular flavors. Eggplants are forced under glass to a limited extent for home use. They require the temperature of a tomato house, and great care must be taken to keep off red-spider and mites.

In order to insure large fruits, practise artificial pollination. Non-pollinated fruits will grow for a time, but always remain small (Fig. 1379).

1379. Non-pollinated fruit.

*Soil.*—Eggplant will grow on almost any land in the South, but it develops to greater perfection on a rich, deep, loamy soil free from debris. In the clay districts this is not easily secured, but there are often small fields that are sufficiently dry and yet contain enough sand to make eggplant-growing profitable. No matter whether clay land, loam or sandy land be employed for raising this crop, it will be necessary to plow deeply and thoroughly. The land should be drier than that required by cabbage or beets. In fact it will stand a greater drought than the ordinary vegetables. On the other hand, one should not attempt to grow a crop on land that is composed of large particles, such lands as are ordinarily called "thirsty" in the vegetable-growing sections of Florida.

*Fertilizer.*—On the coastal plains of the South Atlantic and Gulf States, barn manure is of doubtful value for fertilizing eggplant. When it is advisable to use this material, it is preferable to compost it and use it in the form of well-rotted stable manure. A cheaper and at the same time preferable way of securing the humus necessary in the loamy sands is to grow leguminous plants that are not subject to root-knot. Such plants will give much more humus and at a cheaper price than can be obtained by the use of stable manure. On the loamy sands, the fertilizer should not be applied until after the plants have been set out and have started. A small quantity is then applied by hand or by drill. On very poor land, as much as 200 to 500 pounds of a good home-mixed fertilizer should be used. In the course of two to four weeks, the eggplants will have shown the effect of the fertilizer and by this time will be making a considerable growth. A second application may then be made of as much more, or twice as much as was used the first time. Later in the season, when the plants are beginning to make bloom buds or setting the fruit well, an after-dressing of nitrate of soda could be applied if the plants show need of further fertilizing, using it at the rate of 100 to 300 pounds to the acre. This can be applied very readily by hand or by the use of a fertilizer drill. The hand method is more economical of fertilizer but more costly in applying. On the heavy clay lands less potash will be needed and in those places in which a stiff clay is employed for gardening purposes, the potash may be reduced to 4 or 5 per cent, or even eliminated. Ammonia and phosphoric acid are needed on nearly all the soils.

*Propagating the seedlings.*—The time required to bring plants into bearing from seeds varies with the condition of the soil and the temperature. During cool weather the plants grow very slowly, but during hot weather they grow rapidly and mature fruit in much less time. Those who wish to have early fruit and are able to use hotbeds or propagating-houses should sow the seed 120 to 150 days before the fruit is wanted. Pre-

pare the hotbeds as for other seedlings, and sow in rows a few inches apart. When these are beginning to show their leaves or when the seedlings are beginning to look spindly, they should be pricked out and transferred to another bed. In this each plant should be given about a 2-inch square; then they may be forced until the plants crowd one another in the bed, when they should be transferred again. When the plants have attained the size of 6 inches, and the atmosphere will permit, they may be set out in the field. A somewhat more laborious, but at the same time more successful plan, is to plant the seedlings in 2-inch flower-pots and then shift to larger ones as often as the plants become pot-bound or crowd one another in the bed. Fig. 1380 represents a plant three-tenths natural size, just taken from a flower-pot and ready to be shifted to a larger one. By shifting until 6-inch pots are reached, the eggplant may be forced along without injury to blooming size or even to a size when fruit is beginning to set, and then set out in the field without injury to the plants or crop. Eggplant-growers should bear in mind constantly that from the time of sprouting the seeds to the harvesting of the crop, the plants cannot stand a severe shock in their growth without detriment to the crop. When the plant is once started, it should then be forced right along and never allowed to become stunted during its growth. The amount of damage done by neglecting plants before they are set in the field varies with the severity of the shock and the length of time during which the plant undergoes the disadvantageous conditions. If it becomes necessary to harden the plants off before setting them in the field, this should be done gradually.

*Culture in the field.*—After the field has been thoroughly prepared in the way of plowing and fertilizing, which should have been done at least two weeks before the plants were set out, the rows should be laid off 3 to 4 feet apart. The plants may be set 2 to 4 feet apart in the row, varying with the varieties to be used and the soil. Tillage should be continued and varied according to the conditions of the weather. In a wet season it is well to cultivate the land as deeply as possible, while in dry weather cultivation should be shallow, simply sufficient to keep the weeds from growing, to keep the soil well aired, and to keep mulching of dry soil on the land. Under ordinary circumstances it does not pay to prune or pinch out the buds, but when the season is short this may be resorted to with some advantage. If it is desirable to have the fruit attain a certain size before frost, one may begin to pinch out the blossoms and new growth about three weeks before its usual occurrence. This same process will be of advantage when the fruit is to be brought into market at a certain time. A great many attempts have been made to hold eggplants

1380. Pot-grown plant ready for setting in the field.

over the summer, that is to have a spring cropping and then allow the plants to remain in the field, cultivate them up and make a fall crop from the old stalks. Sometimes this process is successful but generally speaking it is a wasteful and expensive method. The old plants that have borne a crop should be discarded and a fresh seed-bed started to bring the plants in at the

time desired. If about 150 days are allowed from the time of sowing the seed, the grower will have a good field of fresh plants to start in with, which will produce a higher quality and larger quantity of fruit.

**Marketing.**—It is better to cut the fruit from the plant than to attempt to break it, especially if the work is being done by careless laborers. After cutting the fruit, it may be placed in large baskets and hauled to the packing-house for crating. Each fruit should be wrapped separately in heavy paper, either manila or brown, and care must be exercised not to wrap it while moist. Formerly the large crate was generally employed, but in the last ten years there has been a decided tendency toward reducing the size of the crate. The eggplant crate is now about double the size of the bean crate, and usually ships at the 80-pound rate. The eggplant is regarded as a staple vegetable, consequently fancy wrapping-paper or fancy methods of packing do not pay for the trouble. It stands shipment well to distant markets, so that freight shipments are usually employed. At times in the winter and spring, the price of eggplant becomes very high and then the shipments go forward by express.

**Varieties.**—There are only a few varieties offered in the market. The New York Improved Spineless matures a little earlier than the Black Pekin. The New York Purple (Fig. 1381), Black Pekin and the New York Spineless are excellent for shipping purposes. The above varieties are the black-fruited, and the most popular in the United States, while the white-fruited sorts are said to be the most popular in Europe. For home use, the white-fruited varieties are preferable, but as these make poor sellers in the United States, one must raise the purple sorts for market. For home gardens, the early and small Early Dwarf Purple (Fig. 1382) is useful. It is particularly recommended for northern climates. There are three main types of eggplants, as follows: The commoner garden varieties, *Solanum Melongena* var. *esculentum*, Bailey (Figs. 1381, 1383); the long-fruited or "serpent" varieties, *S. Melongena* var. *serpentinum*, Bailey; the Early Dwarf Purple type var. *depressum*, Bailey (Fig. 1382). See *Solanum*. The so-called Chinese eggplant is a different species, for which consult *Solanum*.

**Seed-growing.**—This is by no means a difficult operation and may be done profitably in certain sections of the South. For this purpose all defective or dwarfed plants in the field should be cut out. By a little attention one will be able to know when the seeds have matured sufficiently for gathering. At this time the eggs usually turn a lighter color or even somewhat yellow. The fruit should be gathered and carried to the

packing-house, where it may be left in a pile for two or three days, as there is very little danger from rotting. When a sufficient number have been collected, the laborers may be set to paring off the extra amount of meat on the outside of the seed. The remaining core may then be cut longitudinally into quarters or eighths,

1382. Sprays of Early Dwarf Purple eggplant.

using a dull knife to avoid cutting the seed. After a quantity of these have been pared, they may be placed in a barrel and covered with water. The barrel should not be made more than two-thirds full. In a day or two fermentation will set in and the meaty portion will macerate from the seed. The seed may then be separated from the meat by means of sieves, using first wide-meshed ones to remove the meat and then finer-meshed ones to screen out the seed from the finer pulp. The seed should not be allowed to stand more than two or three days in the macerating barrel, as the heat evolved by fermentation and the heat of the summer is liable to cause them to germinate. After separating the seed from the pulp, it should be dried in the shade and wrapped in secure packages. By covering with tin-foil or oil-paper, the atmospheric moisture will be kept out and molding prevented.

**Diseases.**—The most destructive of diseases in the lower South is a blight fungus which attacks the plant just beneath the surface of the ground, causing the softer tissues at this point to rot off and the plant to die. The fungus is not able to penetrate the harder portion of the stem, consequently the plant lingers along for weeks after being attacked. A number of attempts have been made to cause this blight fungus to produce fruiting organs so it could be classified, but up to the present this has proved futile. In such cases as this there is no remedy. After the plant is attacked, it is usually doomed. Much, however, can be done in the way of preventing the spread of this fungus. If all plants are destroyed as soon as found to be affected, the fungus cannot perfect its sclerotia, or rusting state, and thus its propagating is prevented. The normal home of this fungus is in decaying vegetable matter. If, therefore, a field is kept free from this sort of material one will do much to prevent this fungus from being present. Some soluble form of fungicide, as Eau Celeste or potassium sulfide, may be sprayed about the roots of the plants to good advantage. Practise rotation of crops. A second form of blight is caused by *Bacillus solanacearum*. This disease has its origin of infection in the leaves, and is introduced by means of insects

1381. Field-grown plant of New York Improved eggplant.

which have fed upon diseased plants and carried the infection to the well ones. The disease works rapidly down the tissues and causes the death of the leaf and finally of the whole plant. The only remedy for this is to destroy all plants that are affected with the disease as soon as detected, and kill off all insects. When this disease is known to be present in a section, it is best to set the plants as far apart as practicable. In this way the danger of infection from insects is somewhat reduced. When the disease is known to be present in a field it should not be planted to this crop. Anthracnose (*Glaesporium melongenæ*) does not cause great damage to this crop, but is one of the agents that reduce the profits. "It may be recognized by its producing decided pits in the fruit, upon which soon appear minute

1383. Long White eggplant.

blotches bordered with pink." Bordeaux mixture may be used to good advantage for preventing this disease. *Phoma solani* frequently causes damping-off in the hotbed. It often renders a whole bed worthless. Plants affected with this fungus usually fall over as if eaten off by some insect. Some plants, however, continue a miserable existence and finally die. Careful examination will reveal the point of injury, which is at the ground-level. The best preventive is to use well-drained beds and then avoid excessive watering. When damping-off is detected in a seedling bed, the atmosphere and surface soil should be dried as rapidly as possible, followed by one application of fungicide.

**Insect enemies.**—Among the most annoying of the insect enemies is the cutworm (larvæ of Noctuidæ). These insects are almost omnipresent, and when nearly full grown are liable to cut off plants that are 4 or 5 inches high. It is not common for one insect to cut off more than a single plant, but in ordinarily fertile soil there are enough cutworms present to destroy the entire field. So that, on the whole, it becomes very annoying. When these insects are quite destructive, it is possible to kill them with poisoned bran or poisoned

cottonseed meal, sweetened with syrup or sugar. Another insect that does more or less damage is the cotton bollworm (*Heliothis armiger*). This insect does its damage by boring a hole into the stems or the fruit. In the latter case it causes it to rot before it is picked, or possibly in transit. As the fruit becomes larger there is less danger of attack from this insect, so that the main trouble occurs in the earlier stages of its growth. The eggplant aphid (*Siphonophora cucurbitæ*) is one of the most annoying pests to this crop. It usually makes its appearance about the time the crop is fit to ship, and appears in such numbers that the plants are ruined in the course of a week or two. The insect attacks the lower surface of the leaves, making it difficult to reach the pests with insecticides, but persistent efforts and a good tobacco decoction, applied with a fine nozzle, will give considerable relief. Sulfur spray or other mild contact insecticide will be found more uniformly effective than tobacco decoction. Whale-oil soap is an excellent insecticide to use. Kerosene emulsion and insecticides made from the miscible oils, largely employed in proprietary insecticides, should be avoided. While they may be used effectively, there is considerable danger from scalding in handling by indifferent laborers.

P. H. ROLFS.

**EGLANTINE:** *Rosa rubiginosa*; also applied to *Rubus Eglantaria*, *Rosa Eglantaria*, and perhaps *Lonicera Periclymenum*.

**EGYPTIAN LOTUS:** *Nymphaea Lotus*; also *Nelumbium*.

**EHRËTIA** (G. D. Ehret, botanical painter, born in Germany, 1708 or 1710, died in England 1770). *Boraginaceæ*. Tender trees and shrubs, found in the warmer regions of the world.

Plants with or without rough, short hairs: lvs. alternate, entire or dentate: fls. small, often white, in cymes, corymbs, terminal panicles, or rarely all borne in the upper axils; calyx 5-parted or -cleft; corolla short-tubed, rotate, with 5 obtuse spreading lobes; stamens 5, affixed in the tube, exerted or rarely included, the filaments very slender; style 2-lobed or -parted: fr. a small drupe, usually containing two 2-celled 2-seeded nutlets.—Species 40–50, the larger number in the Old World tropics, but widely dispersed about the globe. A few species are planted in S. Calif. and perhaps elsewhere along the southern parts.

A. Lvs. toothed.

B. Foliage hairy.

**macrophylla**, Wall. Tree: lvs. 6–8 in. long, broadly elliptic, acuminate, bristly above and soft-hairy beneath, serrate: panicle terminal, pubescent; calyx ciliate: fr. globose, obscurely 4-grooved. Himalayas, China.

BB. Foliage not hairy.

**acuminata**, R. Br. (*E. serrata*, Roxbg.). **HELIO-TROPE TREE**. Tree, to 40 ft.: lvs. 3–4 in. long, elliptic to oblong, acuminate, serrate: panicles terminal and axillary; fls. clustered, sessile; corolla-tube very short. Trop. Asia, Japan and Austral. B.R. 13:1097. Hardy at Arnold Arboretum.

AA. Lvs. usually not toothed.

**elliptica**, DC. Tree, 15–50 ft. high: lvs. oval or oblong, sometimes serrate, nearly smooth, or with minute hairs and very rough above: fls. small, white, fragrant, in cymes or panicles; calyx-lobes broad-lanceolate and acute, as long as the corolla-tube: fr. a yellow globose drupe, the size of a small pea, with edible thin pulp. Texas, Mex.

WILHELM MILLER.  
L. H. B.†

**EICHHORNIA** (after J. A. F. Eichhorn, a Prussian Minister, born 1779). *Pontederiacæ*. Tropical aquatic herbs, grown for showy flowers and interesting habit.

Perennial, floating, rooting at the nodes: immersed lvs. on young sts. linear; emerged lvs. obovate or

rounded (or rarely lanceolate), the petioles in some species much inflated and acting as buoys: fls. in a spike or panicle, the scape 1-lvd.; perianth funnel-shape with a long or short tube; stamens 6, attached unequally in the tube, part of them exserted; ovary sessile, 3-celled; style filiform: fr. a caps. contained in the withering perianth, ovoid to linear.—About a half-dozen species in S. Amer., one reaching Afr.

This genus includes the water hyacinth (see Fig. 1384), the famous "million-dollar weed" that obstructs navigation in the St. John's River, Florida, and is a source of wonder and delight in every collection of tender aquatics in the North. The curious bladders made by the inflation of the petioles help the plant to float freely. About flowering time the plant sends down anchoring roots which, if the water be only 3 or 4 inches deep, penetrate the soil. The true hyacinths belong in an allied family (Liliaceæ); the pickerel weed, in the allied genus *Pontederia*, the ovary of which by abortion is one-celled, and each cell one-ovuled, while *Eichhornia* is three-celled and many-ovuled. The plants of this family have been greatly confused botanically, partly because the fugacious, membranous flowers are not well preserved in dried specimens, and partly because of variation in form of leaves, depending upon whether the plants grow in deep or shallow water, or in mud. The common water hyacinth sends out two kinds of roots, the horizontal ones often thick and fleshy, and apparently for reproductive purposes, the vertical ones long, slender, and clothed with innumerable small, horizontal fibers.

The flowers are most beautiful, and the plant is worthy of special cultivation. It is often called a water-orchid, being of such delicate coloring and texture. The plants must be more or less stationary although it is a floating plant, for they will not flower when drifted about by any light breeze or where the water is 2 or more feet deep as is often the case where nymphæas are grown. A depth of 9 to 12 inches of water is sufficient with a guard to keep the plants in bounds. Good soil underneath is necessary so that the plants will derive some nourishment. They will grow rapidly and flower profusely all through the season, and it may be necessary to thin out the plants, for when too crowded the petioles will become elongated and the plants unsightly. They can also be grown in a tub or tank observing the same method of culture. Propagated by division. (Wm. Tricker.)

A. *Lf.-stalks inflated: inner perianth-segms. not serrated.*

**crassipes**, Solms (*E. speciosa*, Kunth. *Pontederia crassipes*, Mart.). Fig. 1384. Lvs. in tufts, all constricted at the middle, bladder-like below, sheathed, many-nerved: scape 1 ft. long, with wavy-margined sheaths at and above the middle; fls. about 8 in a loose spike, pale violet, 6-lobed, the upper lobe larger and having a large patch of blue, with an oblong or pear-shaped spot of bright yellow in the middle; stamens 3 long and 3 short, all curved upward toward the tip. Brazil. B.M. 2932 (as *Pontederia azurea*). I.H. 34:14. A.F. 5:511. Var. *majör*, Hort., has rosy lilac fls. Var. *azùrea*, Hort., has yellowish fls.

AA. *Lf.-stalks not inflated: inner perianth-segms. beautifully serrate.*

**azùrea**, Kunth. Lvs. on long or short not-inflated petioles, very variable in size and shape: scape often as stout as the lf.-stalk, gradually dilated into a hooded spathe; fls. scattered or crowded in pairs along a stout, hairy, sessile rachis; perianth bright pale blue, hairy outside, inner segms. beautifully toothed, the upper a trifle larger, with a heart-shaped spot of yellow, which is margined with white. Brazil. B.M. 6487. G.C. II. 25:17. I.H. 34:20. R.H. 1890:540.—One plant will become 5 or 6 ft. across in a season.

*E. paniculata*, Spreng. Fls. in a compound spike or panicle, 2-lipped, purple and blue and with large white spots: lvs. long-petioled, cordate-acuminate, without petiole bladders: st. 12–18 in., often several. B.M. 5020 (as *E. tricolor*).

WILHELM MILLER.

**ELÆAGNUS** (ancient Greek name, meaning a kind of willow; from *elaïos*, olive). *Elæagnacæ*. Shrubs and small trees, grown chiefly for their handsome foliage and for their ornamental fruits, edible in a few species.

Deciduous or evergreen, sometimes spiny: lvs. alternate, short-petioled, entire, clothed more or less with silvery or brownish scales: fls. axillary, solitary or in clusters, apetalous, perfect; perianth campanulate or tubular, 4-lobed; stamens 4, included, on very short filaments: fr. a 1-seeded drupe.—About 40 species in S. Eu., Asia and N. Amer. Monograph by Servettaz in Bot. Centralblatt, Beihefte 25, pt. 2:1–128 (1908).

1384. *Eichhornia crassipes*.

These are highly ornamental shrubs with handsome foliage and mostly decorative fruits; the flowers are inconspicuous, but mostly fragrant. Some of the deciduous species, as *E. argentea*, *E. multiflora* and *E. umbellata*, are hardy North, while the evergreen ones are hardy only South. A distinct feature of some species, as *E. argentea*, *E. angustifolia* and *E. parvifolia*, is the conspicuous silvery hue of their foliage, while *E. multiflora* and *E. umbellata* are the most ornamental in fruit.

They grow in almost any well-drained soil, including limestone, and prefer sunny position. Propagation is by seeds which do not germinate until the second year and ought to be stratified and sown the second spring, and by cuttings of mature and half-ripened wood; also sometimes increased by layers and by root-cuttings; varieties and rarer kinds can be grafted on seedlings of vigorous-growing species.

A. *Lvs. deciduous.*

B. *Winter-buds and lvs. beneath and usually the branchlets silvery white, without any brown scales.*

1. *angustifolia*, Linn. (*E. hortensis*, Bieb.). OLEASTER. Shrub or small tree, to 20 ft., sometimes spiny:

lvs. lanceolate or oblong-lanceolate, quite entire, light green above, 2-3 in. long; fls. short-pedicelled, 1-3, axillary, on the lower parts of the branches; perianth campanulate, tube about as long as limb, yellow within, fragrant; style at the base included by a tubular disk: fr. oval, yellow, coated with silvery scales. June. S. Eu. W. Asia to W. Himalayas. Var. *orientalis*, Dipp. (*E. orientalis*, Linn. f. *E. hortensis* var. *orientalis*, Schlecht.). Often spineless: lvs. often oblong or oval, usually rounded at the base, clothed more with stellate hairs beneath than with scales, usually glabrous above at length: fr. rather large to 1 in. long. A.G. 21:405, 519, 613, 645. Var. *spinosa*, Schneid. (*E. spinosa*, Linn.). Spiny: lvs. linear-lanceolate or lanceolate, narrowed at the base, scaly above and densely scaly beneath: fr. smaller. L.B.C. 14:1339. B.R. 1156.

2. *parvifolia*, Royle (*E. japonica*, Hort. *E. umbellata* var. *parvifolia*, Servettaz.). Shrub or small tree to 20 ft., with erect sts. and spiny, spreading branches: lvs. elliptic-ovate or oblong-lanceolate, crisped at the margin, usually with stellate hairs above, glabrous at length, silvery beneath,  $1\frac{1}{2}$ -3 in. long; fls. axillary, usually crowded on short lateral branchlets, short-pedicelled; perianth narrow, tube longer than limb, whitish within, fragrant: fr. globose or nearly so, densely silvery when young, pink when ripe,  $\frac{1}{8}$  in.

1385. *Elaeagnus multiflora*. ( $\times \frac{1}{4}$ )

long. June; fr. in Aug. Himalayas, China, Japan. B.R. 29:51. Mn. 5:145.—Not quite hardy N. Sometimes cult. under the name of *E. reflexa*, which species, however, is evergreen. Var. *japonica macrophylla* is advertised but probably does not belong to this species.

BB. *Winter-buds and branchlets with reddish or yellowish brown scales and sometimes silvery besides; lvs. silvery white beneath, often with few brown scales.*

c. *Fr. juicy, scarlet-red or brownish red.*

3. *umbellata*, Thunbg. Spreading shrub, to 12 ft., often spiny, with yellowish brown branchlets, often partially silvery: lvs. elliptic or oval to ovate-oblong, above usually with silvery scales while young, sometimes glabrous, often crisped at the margin,  $1\frac{1}{2}$ -3 in. long; fls. yellowish white, fragrant, 1-7 in the axils, usually crowded on short lateral branchlets, tube much longer than the limb, slender: fr. globose or oval, scarlet,  $\frac{1}{4}$ - $\frac{1}{3}$  in. long, erect, on stalks  $\frac{1}{3}$ - $\frac{1}{2}$  in. long, clothed with silvery scales, mixed with brown scales while young. May, June; fr. in Sept., Oct. M.D.G. 1899:569. A.G. 12:206. R.H. 1901, p. 85. S.I.F. 2:54.

4. *multiflora*, Thunbg. (*E. longipes*, Gray. *E. edulis*, Sieb.). GUM. Fig. 1385. Shrub, to 6 ft., with reddish brown branchlets: lvs. elliptic, ovate or obovate-oblong, with stellate hairs above, usually glabrous at length, mostly with scattered brown scales beneath, 1-2 $\frac{1}{2}$  in. long; fls. usually solitary in the axils, sometimes 2 on the lower part of the branches or on short branchlets, yellowish white, fragrant; tube as long as the limb: fr. pendulous, oblong,  $\frac{3}{4}$  in. long, scarlet, on

slender pedicels, much longer than the fr.; fr. with brown scales when young, ripening in June or July, of agreeable, slightly acid flavor. April, May. Japan, China. B.M. 7341. L.I. 4. G.F. 1:499. G.C. 1873: 1014. G.M. 31:715. B.H. 33:217. F.E. 13:830. A.G. 1890:565. M.D.G. 1901:573. Gng. 1:275, 277. Var. *rotundifolia*, Servettaz. (*E. rotundifolia*, Gagnaire). Lvs. broadly oval, half-evergreen, glabrous above. Var. *ovata*, Servettaz. Lvs. usually with stellate hairs above while young, soon glabrous: fls. 1-3: fr. oval,  $\frac{1}{3}$ - $\frac{1}{2}$  in. long, nodding, with brown scales when young, ripening July or Aug.; pedicels  $\frac{1}{2}$  in. long or longer. Japan. M.D.G. 1899:569 (as *E. multiflora*). Var. *crispa*, Servettaz. Similar to the preceding var., usually spiny: lvs. oblong-lanceolate: pedicels as long as fr.

cc. *Fr. rather dry, silvery white.*

5. *argentea*, Pursh. SILVERBERRY. Erect shrub, to 12 ft., spineless, stoloniferous, with reddish brown branchlets: lvs. ovate or oblong-lanceolate, silvery on both sides, often with scattered brown scales beneath, 1-3 in. long; fls. 1-3, axillary, yellow within, fragrant: fr. oval or roundish oval, densely clothed with silvery scales, short-pedicelled,  $\frac{1}{3}$ - $\frac{1}{2}$  in. long. May, June. Canada, south to Que., Minn., Utah. B.B. (ed. 2) 2:576. B.M. 8369.

AA. *Lvs. evergreen: usually flowering in fall.*

6. *macrophylla*, Thunbg. Spineless shrub, to 6 ft., with silvery white branchlets: lvs. broad-ovate or broad-elliptic, on stout and rather long petioles, scaly above, usually glabrous at length, silvery white beneath: fls. axillary, with silvery and brownish scales outside; tube campanulate, abruptly narrowed at the base, as long as limb. Japan. B.M. 7638. G.C. III. 25:90.

7. *pungens*, Thunbg. Spreading shrub, to 6 ft., mostly spiny, with brown branchlets: lvs. oval or oblong, undulate and often crenulate at the margin, at length glabrous above, silvery beneath, more or less interspersed with brown scales, 2-4 in. long; fls. in axillary clusters; tube cylindrical, slightly narrowed at the base, longer than the limb: fr. short-stalked, about  $\frac{3}{4}$  in. long, with silvery and brown scales. Japan. Var. *Frederici variegata*, Servettaz. Lvs. with yellow center and green margin. Var. *maculata*, Hort. (var. *aureo-maculata*, Hort.). With a large yellow blotch in the middle. A. G. 13:122. A.F. 23:1015. Var. *Simoni*, Rehd. (*E. Simoni*, Carr.). Lvs. rather large, oblong-elliptic, with few brown scales beneath or nearly without. Var. *Simoni tricolor*, Hort. Lvs. like the former, but variegated with yellowish and pinkish white. Var. *reflexa*, Rehd. (*E. reflexa*, Morr. & Deene.). Branches elongated and flexile: lvs. ovate-lanceolate, acute or acuminate, lustrous above, only scaly while young, ferruginous below. H.U. 4:328. Var. *variegata*, Rehd. (var. *aurea*, Servettaz., var. *aureo-variegata*, Hort.). Lvs. margined yellowish white. G.M. 54:327.

*E. ferruginea*, A. Rich. Spineless evergreen shrub, with spreading brown branches: lvs. with yellowish and brown scales beneath: perianth with quadrangular, abruptly contracted tube: fr. long-stalked. Japan.—*E. glabra*, Thunbg. Spineless evergreen shrub, with brown branches: lvs. shining above, with yellow and brown scales beneath: perianth with slender, tubular tube, gradually narrowed toward the base, twice as long as the limb: fr. short-stalked. Japan. S.I.F. 2:54.

ALFRED REHDER.

ELÆIS (Greek, *olive*). *Palmaceæ*, tribe *Cocoinææ*. Tropical spineless palms with pinnate foliage, of which the best known is the oil palm of western Africa, whose red fruits, borne in large clusters, yield the palm oil of commerce, which is used in making candles and soap.

Leaves terminal, numerous, large and pinnately divided, the segms. sword-shaped, the margins in some species spiny: spadix short and thick. Young plants are grown for ornament in S. Calif., and in the N., but it is not hardy outdoors in U. S., according to Franceschi. The other 6 species are from Trop. S. Amer. The genus is separated from *Cocos* by the 1-3-seeded frs., with 3 pores above the middle.

**guineënsis**, Jacq. **OIL PALM**. Sts. stout, 20–30 ft., coarsely and deeply ringed: lvs. 10–15 ft.; petiole spiny-serrate; lfts. 50–60, linear-lanceolate, acute, the same color above and below. F.S. 14:1492.—From an early stage in growth, this is one of the most ornamental palms. Until it reaches several feet in height, it is a slow grower, consequently one does not see much of it, except in collections. It does best in a warm temperature, although it will thrive in an intermediate house. Seeds are always obtainable from several of the large European houses. It is but little grown as a commercial palm, as young plants do not show their full character. Given same treatment as *Areca lutescens*, will grow well. This treatment includes night temperature of 65° and plenty of water.

JARED G. SMITH.  
N. TAYLOR.†

**ELÆOCÁRPUS** (Greek, *olive-fruit*). *Elæocarpææ*; formerly included in *Tiliææ*. Tropical trees, with showy flowers, in their juvenile stages also sometimes cultivated under glass.

Leaves simple, usually alternate; to 50 and 60 ft. high or some of them practically shrubs in cult.: fls. perfect or polygamous, in axillary racemes; sepals distinct, 4 or 5; petals 4 or 5, cut or fringed (rarely entire), attached about a thickened torus; stamens many (rarely 8–12), with long-awned anthers opening by a slit at the apex; ovary 2–5-celled: fr. a drupe, with a large and bony stone, sometimes 1-celled by abortion. —Perhaps 100 species, in the Old World tropics. They are little known in cult. but are sometimes mentioned in greenhouse lists. The pulp of the fr. in some species is said to be edible; and the interesting sculptured stones of some kinds (as of the bead-tree of India, *E. Ganitrus*, Roxbg.) are used for beads, heads of ornamented pins, and other decorations. They propagate by ripened shoots with the lvs. left on, and also by seeds when obtainable.

**grandiflorus**, J. Smith. A much-branched shrub, about 7 ft. high under glass: lvs. considerably clustered at the ends of branches, 3–6 in. long, broadly lanceolate; petiole  $\frac{1}{4}$ –1 in. long, with a few distant saw-teeth, or more or less round-toothed or wavy-margined: sepals 5, red outside, white inside; petals 5, white or pale yellow, silky outside, fringed. Java. B.M. 4680 (as *Monocera grandiflora*). F.S. 8:817. J.F. 4:339.—Lvs. rather leathery, dark green above, paler beneath. Warmhouse. Prop. by cuttings of nearly ripened wood.

**cyaneus**, Sims (*E. reticulatus*, Smith). Under glass a shrub, but in the wild a small tree and sometimes reaching 60 ft., glabrous: lvs. elliptic-oblong, or lance-oblong, acuminate, prominently reticulate: fls. cream-white, fringed, in loose racemes that are shorter than the lvs.; stamens many: drupe globular or nearly so, blue (whence the specific name). Austral. B.M. 1737. B.R. 657. G.C. III. 36:272; 51:393. G.M. 55:423. G. 34:389. Gn. 77, p. 301. L. H. B.†

**ELÆOCÓCCA**: *Aleurites cordata*.

**ELÆODÉNDRON** (Greek for *olive tree*, from the resemblance of the fruit). *Celastrææ*. Tropical shrubs or small trees, some kinds of which are grown in the juvenile state under glass for the interesting foliage.

Leaves simple, entire or crenate, opposite or alternate, thickish, frequently evergreen: fls. inconspicuous, greenish or white, in axillary or lateral clusters; calyx usually 4–5-parted; petals 4–5, and exceeding the calyx; stamens 4–5, inserted under the edge of the thick disk; ovary single, mostly 3-celled; style very short: fr. a small fleshy or nearly dry drupe.—Species probably upward of 40, in Afr., India to Austral., and somewhat in S. Amer. Very closely allied to Cassine, a South African genus.

**orientale**, Jacq. A graceful and handsome plant: the mature lvs. are very different from the juvenile lvs., being obovate, obtuse, crenate, cuneate at base, and 2–3 in. long, and the slender graceful young lvs. pass into them by gradual transition: fls. less than  $\frac{1}{4}$  in. across in close axillary cymes which are shorter than the lvs.; pedicels equaling or surpassing the corolla; calyx deeply lobed; petals yellow-green: drupe size of olive, oblong. Madagascar, Mauritius.—The plant holds its lower foliage well, or throws out new foliage to take the place of that which drops. It thrives in either an intermediate or a warmhouse. Prop. by single eye cuttings in small pots, kept rather warm. It has been said that *Aralia Chabrieri* of gardens belongs to this species (although of a different family), but this is apparently an error. See *Polyscias* for a discussion of this plant.

**australe**, Vent. Intro. into S. Calif. from Austral., and prized for its holly-like foliage. In its native habitat it is a tree 30–40 ft. high, producing useful close-grained wood: lvs. mostly opposite, ovate to oblong-lanceolate, nearly or quite obtuse, entire or open-crenate, coriaceous, very reticulate beneath: fls. with parts in 4's: drupe about  $\frac{1}{2}$  in. long, red, ovoid or globular. L. H. B.

**ELAPHOGLÓSSUM** (Greek, *serpent tongue*). *Poly-podiææ*. A large group of tropical ferns, with creeping rootstocks and simple leaves.

The sporangia cover the entire under surface of the fertile leaves which are usually much smaller than the sterile ones. Nearly all the species are free-veined but a few have netted venation.—There are 80–100 species in the tropics of both hemispheres. They were formerly included under *Acrostichum*. All require warmhouse treatment, an abundance of water at the roots, and an open porous compost.

gorgoneum, 11.	pilosum, 5.	

#### A. Veins all free.

#### B. Surface of lvs. densely scaly throughout.

#### c. Texture thin, flaccid.

1. **villosum**, J. Smith. Fig. 1386. Sterile blades 6–9 in. long; fertile lvs. scarcely more than half as large, both with abundant slender, dark brown scales. Mex. and W. Indies. —Dwarf, variable.

#### cc. Texture thick, leathery.

2. **hirtum**, C. Chr. (*Acrostichum squamodum*, Swartz). Sterile blades 6–12 in. long, the fertile narrower, on longer sts., both surfaces matted with bright reddish brown linear or lanceolate scales. Tropics of both hemispheres.

3. **muscosum**, Moore. Sterile blades 6–12 in. long, fertile much shorter; upper surface slightly scaly, the lower densely matted with ovate, rusty scales. Tropics of both hemispheres. S. 1:211 (as *Acrostichum*).—Very distinct in habit, and an interesting greenhouse species.

#### BB. Surface of lvs. slightly scaly.

4. **petiolatum**, Urban (*Acrostichum viscosum*, Swartz). Sterile blades 6–12 in. long, narrowed gradually at the base: the fertile shorter, on longer stalks; texture

1386. *Elaphoglossum villosum*. ( $\times \frac{1}{2}$ )

leathery, the surfaces somewhat viscid. Tropics of both hemispheres.

5. *pilōsum*, Moore. Blades flexuous, 6-8 in. long,  $\frac{3}{4}$  in. wide, with tufts of star-like scales beneath; texture herbaceous. Mex. to Colombia.—Chiefly of botanical interest.

BBB. Surface of lvs. not scaly; texture leathery.

c. Margins of lvs. thick, cartilaginous.

6. *simplex*, Schott. Sterile blades 4-12 in. long, with a very acute point, the lower portion gradually narrowed into a short, somewhat margined stalk. W. Indies to Brazil.

7. *confōrme*, Schott. Sterile blades 2-9 in. long, with a bluntish point and wedge-shaped or spatulate base; fertile lvs. narrower. Tropics of both hemispheres.

cc. Margins of lvs. not thickened.

8. *flāccidum*, Moore. Sterile blades 6-12 in. long, with very acute point, the lower portion gradually narrowed to the short stalk; fertile lvs. on stalks 3-4 in. long. S. Amer.—Of botanical interest only.

AA. Veins uniting to form a network.

B. Surface of lvs. densely clothed with narrow scales. (*Hymenodium*.)

9. *crinitum*, Christ. ELEPHANT-EAR FERN. Fig. 1387. Blades 10-18 in. long, 4-8 in. wide, on densely scaly stalks; fertile lvs. smaller, on shorter stalks. W. Indies. F.S. 9:936 (as *H. crinitum*).—Omit sand in potting, and avoid over-watering.

1387. *Elaphoglossum crinitum*.

BB. Surface of lvs. mostly smooth, 6-15 in. long.

10. *reticulātum*, Gaud. Blades on distinct stalks, with wedge-shaped bases,  $1\frac{1}{2}$  in. wide; veins forming copious meshes. (*Chrysodium*.) Hawaiian Isls.—Of botanical interest only.

11. *gorgōneum*, Brack. Blades tapering gradually downward to the short stalks, 2-3 in. wide; veins forming meshes only near the margin. (*Aconiopteris*.) Hawaiian Isls.—Of little decorative value.

L. M. UNDERWOOD.

R. C. BENEDICT.†

**ELATINE** (Greek name of doubtful application). *Elatinaceæ*. Small mostly glabrous creeping herbs, probably annuals, of temperate and warm regions (perhaps 10 species), sometimes used in bog- and water-gardening. They root at the nodes, spreading along the margins of streams and ponds. Lvs. opposite or verticillate, mostly broad, entire; fls. minute and inconspicuous, mostly solitary in the axils; sepals and petals

2-4, and stamens as many or sometimes twice as many; styles or stigmas 2-4; pod 2-4-valved. The plants are grown for their foliage cover. Four species are native in the U. S. and Canada, but they appear not to be in the trade. Abroad, *E. macrópoda*, Guss., of the Medit. region, is offered. Lvs. oblong, short-petioled; fls. axillary and terminal, 4-merous, stalked; caps. half shorter than the sepals.

The family *Elatinaceæ* is allied to the *Hypericaceæ*. It comprises perhaps 25 species in many parts of the world. The only other genus is *Bergia*, which differs from *Elatine* in being terrestrial and in having 5-merous fls. *B. texana*, Seub., occurs in swamps and on wet banks from S. Ill. to Texas and Calif. The *Bergias* are apparently not in cult.

L. H. B.

**ELDER AND ELDERBERRY:** *Sambucus*.

**ELECAMPANE:** *Inula Helenium*.

**ELECTRO-HORTICULTURE** is a term used by Siemens to designate the application of the electric light to the growing of plants. The term is an unfortunate one, since the use of electric light is not an application of electricity to plant-growing, but is a way of securing illumination. Any strong artificial light hastens assimilation and thereby causes plants to grow more rapidly. The practical questions to be considered are, therefore, the expense of using the light, and whether there are injurious elements in the spectrum of the given light.

The spectrum of the electric arc light is the spectrum of carbon plus that of certain gases incident upon combustion. The spectrum of the arc light is rich in rays which light beyond the luminous part, and these rays are very injurious to most plants. These rays of the ultra-violet part of the spectrum are eliminated by a plain glass, so that when the electric light is surrounded by a globe, or when the light is hung above the roof of the greenhouse, the injuries are reduced to a minimum. Experiments at Cornell University showed that each kind of plant behaves in its own way in the presence of electric light. It is not possible to prophesy what the results may be in a given species, without experiment. A few plants, as tomatoes, cucumbers, melons and carrots, seem to be very little affected either injuriously or beneficially. Nearly all flowers are hastened into bloom by the influence of the light, and their colors are often brighter than under normal conditions; but in very many cases they do not last so long. The best results are secured if the light is applied to the plants when they have reached nearly or quite their full stature. If applied very early in its growth, the plant tends to make flowers before it has attained sufficient size. In floriculture, therefore, the practical value of the electric arc light seems to be its influence in hastening the flowering of certain plants in dark climates, or when plants must be had for a definite season. For example, if the light is applied to Easter lilies for a month before their normal blooming time, the period of bloom may be hastened four to ten days.

Lettuce has shown greater beneficial results from the application of the electric light than any other plant with which careful experiments have been made. Lettuce which receives light from the arc lamp for half of each night may be expected to reach marketable size from one to two weeks before that which is grown in normal conditions.

As a rule, better results are secured when the light runs only half the night. A common two-thousand candle-power light has a marked effect on the growth of many plants at a distance of sixty to even one hundred feet. The incandescent light has a similar influence, but not so marked. It has no injurious effect, however.

As now understood, the application of the electric light to the growing of plants is a special acceleration to be used when the climate is abnormally cloudy or

when it is desired to hasten the maturity of crops for a particular date. Only in the case of lettuce is it yet thought to be of any general commercial importance; and even with lettuce, it is doubtful whether it will pay for its cost in climates that are abundantly sunny. For the literature of the subject, consult the publications of the experiment stations of Cornell University and of West Virginia. See the article *Light*, Vol. IV.

*Electroculture* is a term employed to designate any culture of plants under the influence or stimulus of electric currents. The electric stimulation may arise from the electrification of the atmosphere in the immediate vicinity of the plants, or from the application of electric currents to the plants themselves. In either case, electricity exerts an appreciable and often a very marked influence, resulting in accelerated germination and growth (see the discussion, pp. 30-35, Vol. II, *Cyclo. Amer. Agric.*).

In recent years much more attention has been given to the stimulation of plants by electricity directly through the atmosphere than through the soil. According to experiments made at the Massachusetts Experiment Station, this method appears to be successful and offers a most promising field for future research. Of the various methods used to stimulate plants by electricity, direct currents applied through the soil prove less valuable than alternating currents or static charges. In a series of experiments made with radish plants in closed glass cases, an average increase of 50 per cent was secured, and in another case 45 per cent increase when the case was charged from a static machine with an average potential of 150 volts for a few minutes each day. There are some obstacles in the way of electrically treating plants by the use of high tension wires or static machines owing to the possibility of grounding through steam-pipes and iron posts, and nothing very definite has been obtained as yet from this method. High tension wires (100,000 volts, more or less) have been used in the field with fairly good results, but winds affect a charged atmosphere to a certain extent. The use of high poles provided with points to collect atmospheric electricity has proved successful in laboratory experiments for the stimulation of plants and the fixation of nitrogen, and in the future probably some such method will become of practical use. At present the various methods cannot be considered as of great economic importance. (G. E. Stone.)

**ELEOCHARIS** (Greek-made word, meaning *delighting in marshes*). Sometimes written *Heleocharis*. *Cyperaceæ*. Rush-like native plants, mostly of low, wiry growth, and commonest in marshes and on muddy shores, mostly perennial. The culms are simple, terete or angular, bearing a spherical or oblong head of inconspicuous fls.: lvs. usually reduced to mere sheaths. They are interesting for the borders of ponds, and are very easy to naturalize. Numbers of species are likely to be offered by dealers in native plants; three have been listed: *E. interstincta* R. & S. (*E. equisetoides*, Torr.). A shore plant, with terete knotted culms 2-3 ft. high, and cylindrical heads about the thickness of the culm; resembles horse-tail (*Equisetum*). *E. acicularis*, R. & S. Hair-like, 3-6 in. high, making grass-like mats. *E. ovata*, R. & S. Culms nearly terete, 12-15 in. high; head globose or ovate. *Eleocharis* has about 100 species, widely distributed, of which nearly half occur in Canada and the U. S. L. H. B.

**ELEPHANT'S EAR** is a name for begonias. The elephant-ear *Caladium* is a *Colocasia*.

**ELEPHANT'S FOOT:** *Testudinaria*.

**ELETTARIA** (East Indian name). *Zingiberaceæ*. **CARDAMON.** Hothouse perennial herbs, sometimes seen in collections of economic plants.

Differs from *Amomum* in technical characters, as in the slender tube of the perianth, the presence of internal lobes in the perianth, and the filaments not prolonged beyond the anther. Probably only 1 species, although more have been described. *E. Cardamomum*, Maton (*Cardamomum officinale*, Salisb. *Amomum Cardamomum*, Linn.), affords the small or true cardamoms of commerce, which are the dried capsules and which are used in medicine. Species of *Amomum* yield other kinds of cardamon. The *elettaria* is native to India, but is cult. in Jamaica, and it will no doubt thrive in parts of S. Fla., where plants have been offered. The cardamon plant grows 5-10 ft. high, bearing a curving jointed, closely sheathed st. and oblong-lanceolate acuminate entire nearly sessile lvs. often 2 ft. long rootstock horizontal: fls. purple-striped: caps oblong or nearly globular, with many thin vertical ribs, indehiscent; seeds small, angled. *Gt. 62, p. 93*. It is said to prefer shade and a moist soil. In three or four years plants give full crops, but they become more or less exhausted after bearing three or four crops. Prop. by dividing the roots and by seeds. Under glass, handled the same as *Alpinia*. L. H. B.

**ELEUSINE** (Greek, *Eleusin*, the town where Ceres, the goddess of harvests, was worshipped). *Gramineæ*. **CRAB-GRASS. YARD-GRASS.** Coarse tufted annual grasses, more or less grown as ornamentals; also for the grain in Africa.

The stout unilateral spikes digitate at the apex of the culm; spikelets several-fl'd., awnless, arranged in 2 rows along one side of a continuous rachis; rachilla articulate above the empty glumes; fls. perfect or the upper one staminate: grain loosely inclosed by the lemma and palea.—Species about 6 in tropical regions of the Old World. Some are valued as cereals in Afr., India, and some other eastern countries. For *E. ægyptiaca*, see *Dactyloctenium*.

1388. *Eleusine indica*.  
( $\times \frac{1}{2}$ )

1389. *Eleusine coracana*.  
( $\times \frac{1}{2}$ )

*indica*, Gaertn. **WIRE-GRASS. GOOSE-GRASS.** Fig. 1388. Erect, or in open ground prostrate, 2-4 ft. high: culms flattened: spikes 5-7, about 2-4 in. long, digitate, often with one or two lower down; spikelets 3-6 fl'd. Blooms from June to Oct.—A very common grass in cult. fields and dooryards in the S., often troublesome as a weed on lawns throughout the S. and in Calif.

**coracana**, Gaertn. **AFRICAN MILLET**. Fig. 1389. Erect, 2-4 ft. high, closely related to and much resembling *E. indica*. Can be distinguished from it by its stouter habit, shorter, broader and larger spikes.—Cult. in S. E. Asia for the grain. Beer is brewed from the grain in Abyssinia. In cult. in Amer. as an ornamental grass. *Coracana* means "pertaining to crows."

1390. *Elliottia racemosa*.  
( $\times \frac{1}{2}$ )

**tristachya**, Kunth (*E. barcinonensis*, Costa). Culms tufted, 6 in. to 1 ft. high: lf.-blades short, about  $\frac{1}{8}$  in. wide, obtuse at the apex: spikes broad, mostly 3, digitate, 1-1 $\frac{1}{2}$  in. long,  $\frac{1}{4}$  in. thick; spikelets closely imbricate, 5-flid. India.—Intro. into Amer. on ballast, and in cult. as an ornamental plant.

P. B. KENNEDY.  
A. S. HITCHCOCK.†

**ELEUTHERÏNE** (Greek *free*, referring to the stamens). *Iridaceæ*. Two or three species in the W. Indies and S. Amer., perhaps forms of one; bulbous plants of warmhouse cult., allied to *Cipura* and *Ixia*: fls. white, several on a naked scape, the perianth-tube none and the segms. obovate and spreading; stamens attached to base of perianth-segms., the filaments short and free; ovary oblong, 3-celled; style very short, 3-branched: lvs. long, radical. *E. plicata*, Herb. (*Galathea plicata*, Salisb.), has a large ovoid bulb: root-lvs. 1-2, linear to linear-lanceolate, plicate, 18 in. or less long; scape 6-12 in. high; perianth white, 1 in. or less diam., not lasting: something the general habit of *Babiana*. B.M. 655 (as *Marica plicata*).

**ELEUTHEROCÓCCUS**: *Acanthopanax*.

**ELÍSMÀ** (suggested from *Alisma*). *Alismaceæ*. One species in W. Eu., sometimes grown in water-gardens. It is known also as *Alisma* (p. 246, Vol. I) but has been separated from that genus because of its floating rather than erect habit, sub-solitary fls., and character of the ovules. *E. natans*, Buch., is a slender perennial, with the sts. and developed ovate or oblong lvs. floating: radical lvs. of the original tuft represented by a lf.-stalk which is only slightly or not at all widened at

the top, every succeeding node producing the floating lvs. and roots: fls. 1-3 or 5, large, white, with 3 broad obtuse petals: carpels forming a globular head, each with many slender ribs: summer. Of easy cult.

L. H. B.

**ELLIÓTTIA** (after Stephen Elliott, South Carolina's early and excellent botanist. For a fine portrait and sketch of him, see G.F. 7:204-6). *Ericaceæ*. Deciduous shrub cultivated for its handsome racemes of delicate white flowers.

Leaves alternate, entire, without stipules: fls. in terminal racemes; calyx small, 4-parted; petals 4, oblong; stamens 8, with short filaments; ovary 4-celled; cells 1-ovuled; style slender, exserted: fr. unknown.—One species in S. C. and Ga., very rare and local. The Japanese species formerly referred to this genus are well distinguished by the 3-merous fls. and by the many-ovuled cells of the ovary; they form the genus *Tripetaleia*. Like *Cladothamnus*, *Ledum* and *Leio-phyllum*, the genus differs from most other *Ericaceæ* in having distinct petals, but is easily distinguished from the genera mentioned by its racemose infl. and other characters.

*Elliottia* is very rare in cultivation owing to its difficult propagation; it is not hardy North and seems to grow best in a humid sandy or peaty soil. Propagation by suckers, which appear only occasionally.

**racemosa**, Muhl. Fig. 1390. Shrub, 4-10 ft. high: branches slender: lvs. alternate, oblong, acute at both ends, glandular-mucronate, entire, thin, membranous, 3-4 in. long, 1-1 $\frac{1}{2}$  in. wide; petioles slender, grooved, hairy, about 1 in. long; racemes 6-10 in. long, often branched at the base; calyx-lobes short, rounded; petals spatulate-oblong,  $\frac{1}{2}$  in. long. Wet, sandy woods of S. C. and Ga. G.F. 7:205 (adapted in Fig. 1390). B.M. 8413. G.C. III. 51:11. Gn. 75, p. 471.

ALFRED REHDER.

ELM: *Ulmus*.

**ELODËA** (Greek, *marshy*). *Hydrocharitaceæ*. Aquatic herbs, one of which is grown in aquaria.

The genus is known in horticulture as including the ditch-moss, an interesting hardy perennial plant found in slow streams and ponds nearly throughout N. Amer., except the extreme north and particularly desirable for home and school aquaria. It is a slender, wholly submerged plant, with branching sts. 4 in. to 3 ft. long, according to the depth of the water. The pistillate fls. are raised to the surface by their long calyx-tubes, and float there. The minute staminate fls., which are rarely seen, commonly break off below, rise to the surface, float about, open, and shed their pollen. The fr. ripens below the surface, and the seeds rise. It reached England in 1841 and choked up many canals and waterways, notably the Cam. It was very abundant in 1852 and 1853, but declined in the next few years. Ducks, geese and swans are fond of it, and render great service in getting rid of it. It can be used for manure where it grows in sufficient quantities. Like many other water plants, it makes heavy buds in the fall (Fig. 1391), which drop to the bottom and grow in the spring. This genus contains perhaps 10 species.

**canadensis**, Mich. (*Anácharis canadensis*, Planch. *A. alsinástrum*, Bab. *Philótria canadensis*, Brit.). **WATER-WEED. DITCH-MOSS. WATER-THYME.** Lvs. in whorls of 3 or 4, or the lower ones opposite, linear, minutely toothed or not, 2-7 lines long,  $\frac{1}{2}$ -2 lines wide: fls. white; calyx-tube of the pistillate fls. 2-12 in. long; spathes 5-7 lines long.

1391. Winter bud of *Elodea*. (Nat. size)

Var. *gigantæa*, Hort. GIANT WATER-WEED. A much stronger grower than the species and a desirable plant for the aquarium, and a good oxygenator. Now generally used in preference to the type.

WM. TRICKER and WILHELM MILLER.

1392. *Elsholtzia cristata*.

ELÔDES: *Hypericum*.

**ELSHOLTZIA** (John Sigismund Elsholtz, author of unpublished *Flora Marchica*, the MS. of which is in the Royal Library, Berlin). *Labiata*. Herbs or undershrubs grown chiefly for their blue or lilac flowers appearing in dense spikes late in summer.

Usually aromatic: lvs. opposite, short-petioled, serrate; fls. in usually 1-sided, terminal spikes; calyx tubular or campanulate, 5-toothed; corolla 2-lipped or slightly so; lower lip 3-lobed, the upper undivided, emarginate, concave; stamens 4, exserted; anther-cells diverging; fr. consisting of 4 ovoid or ovoid-oblong nutlets.—Twenty species in E. and Cent. Asia, south to Java, 1 in Eu. and 1 in Abyssinia. Of the cult. species *E. cristata* and *E. Stauntonii* are hardy N., while *E. polystachya* is tender. They are chiefly valued for their late-appearing fls., profusely produced in dense upright spikes; they do not seem particular as to the soil, but demand a sunny position to bloom well. Prop. is by seeds, sown in spring; also with the suffruticose species by greenwood cuttings in summer.

*cristata*, Willd. Fig. 1392. Twelve to 18 in. high, with opposite, petioled, ovate-oblong toothed lvs. and small, light blue fls. in crowded, more or less 1-sided spikes: calyx enlarging in fr. Asia. B.M. 2560.—Hardy annual, with very aromatic foliage and attractive, upright habit. Said to be a good bee plant.

*Stauntonii*, Benth. Undershrub, to 5 ft.: branchlets terete, pubescent: lvs. ovate-oblong to oblong-lanceolate, acuminate, serrate, bright green and glabrous above, lighter green and densely glandular below, 3-5 in. long: fls. lilac-purple, in dense 1-sided spikes 4-8 in. long, usually paniced at the end of the branches; stamens and style long exserted. Sept., Oct. N. China. B.M. 8460. G.C. III. 51:21. Gn. 75, p. 533. M.D.G. 1910:541-2; 1913:52.

*E. polystachya*, Benth. Undershrub, to 6 ft.: lvs. elliptic-oblong to lanceolate, serrate, pubescent on the veins beneath and glandular, 3-5 in. long: fls. white, in very slender spikes 2-6 in. long. Himalayas, W. China.

ALFRED REHDER.

**ÉLYMUS** (Greek name for a kind of millet). *Gramineæ*. LYME-GRASS. WILD-RYE. Erect perennial grasses with terminal usually bristly spikes somewhat resembling rye, sometimes grown as ornamentals and having other uses.

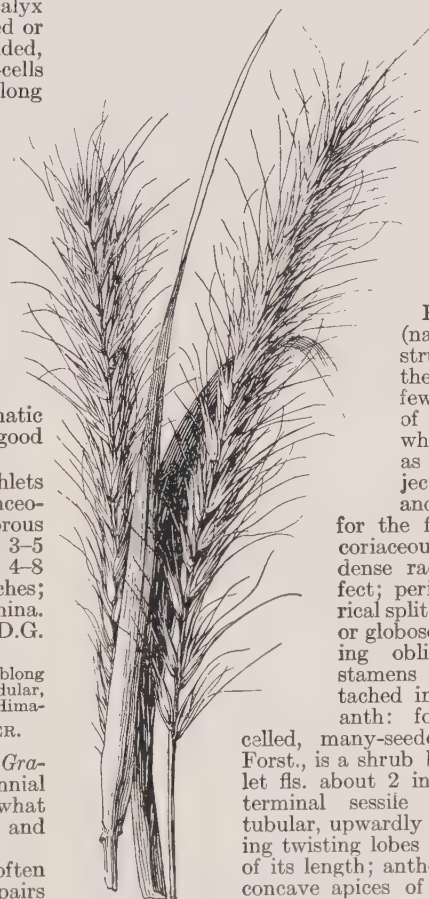

Leaves flat or convolute: spikelets 2-6 fld., often long-awned, the uppermost imperfect, sessile, in pairs (rarely in 3's or 4's), at each joint of the continuous or articulate rachis, forming terminal spikes; glumes acute

or awned, often placed at the front of the spikelet.—Species about 25, in the temperate regions of both hemispheres. For *E. Hystrix*, see *Hystrix*. See p. 3568.

*arenarius*, Linn. SEA LYME-GRASS. Stout, coarse perennial, 2-8 ft. high, with strong, creeping rootstocks: lvs. long, rigid, smooth: spikes dense, terminal, 6-12 in. long; spikelets about 1 in. long and 3-4 fld., awnless. G. 15:701. Dept. Agric., Div. Agrost., 7: 319.—Sometimes used for binding the drifting sands of our Atlantic and Pacific coasts, especially when combined with beach grass, *Ammophila arenaria*. The seed is also used by the Digger Indians for food.

*canadensis*, Linn. CANADA LYME-GRASS. TERREL GRASS. Fig. 1393. Rather stout, smooth perennial, 2-5 ft. high, with broad, flat lvs. 6-12 in. long: spikes 4-9 in. long, exserted, nodding; spikelets very rigid, 3-5 fld.; lemmas long-awned. Common in low thickets and along streams in rich, open woods throughout the country.—Cult. as an ornamental plant. Var. *glaucofolius*, Gray (*E. glaucifolius*, Hort.), is pale and glaucous throughout, with usually more slender awns. Cult. as an ornamental grass.

*condensatus*, Presl. GIANT RYE-GRASS. The largest of the native rye-grasses, growing to the height of 5-10 ft.: culms in dense tufts, stout: spikes 6-12 in. long, very variable, compact or interrupted, bearing branching clusters of spikelets at each joint; glumes subulate; lemmas awnless or mucronate. Rocky Mt. regions and the Pacific slope.—Cult. as an ornamental. A Pacific Coast form has large branched heads.

1393. *Elymus canadensis*. ( $\times \frac{1}{2}$ )

*E. glaucus*, Regel. A glaucous-leaved, dense, caespitose, hardy perennial grass 3-4 ft. high, with very short, smooth lvs. and erect, elongated spikes: spikelets in 2's, erect, usually 5-fld., densely villous-pubescent, short-awned. Turkestan.—Rarely in cult. as an ornamental grass.

P. B. KENNEDY.

A. S. HITCHCOCK.†

## EMBOTHRIUM

(name refers to the structure of the anthers). *Proteaceæ*. A few trees and shrubs of S. Amer., one of which is offered abroad as a greenhouse subject, grown from seeds, and apparently prized

for the fls. Foliage sparse, coriaceous, entire: fls. in dense racemes, showy, perfect; perianth with a cylindrical split tube, the limb ovoid or globose in bud but becoming oblique or recurved; stamens 4, the anthers attached in lobes of the perianth: follicles oblong, 1-

called, many-seeded. *E. coccineum*, Forst., is a shrub bearing bright scarlet fls. about 2 in. long in many-fld. terminal sessile racemes: perianth tubular, upwardly curved, the 4 reflexing twisting lobes representing a third of its length; anthers imbedded in the concave apices of the perianth-lobes; pistil with an elongated cylindrical ovary and long-exserted red style: lvs.

oblong to elliptic, short-stalked, alternate, obtuse and mucronate, pale beneath. Chile. B.M. 4856.—Should be hardy in warm-temperate parts.

**EMÍLIA** (perhaps a personal name). *Compositæ*. Flower-garden herbs, perennial or annual, with orange or scarlet bloom.

Related to *Senecio* (to which some authors refer it), but always without rays: heads rather small, the involucre very simple and cup-shaped, with no small outer scales; style-branches long or short: achenes with 5 acute ciliate angles: florets all perfect.—A dozen or more species have been described from warm parts of Afr., Asia to China, Polynesia and Amer. One species in common cult.

**flammea**, Cass. (*E. sagittata*, DC. *E. sonchifolia*, Hort., not DC. *E. sonchifolia*, Linn., var. *sagittata*, Clarke. *Cacalia coccinea*, Sims, B.M. 564. *C. sonchifolia*, Hort., not Linn. *C. sagittata*, Vahl. *Senecio sagittatus*, Hoffm.). **TASSEL-FLOWER**. **FLORA'S PAINT-BRUSH**. A neat annual, erect, 1–2 ft., glabrous or sparsely hairy, the long sts. terminated by clusters of small scarlet (golden yellow in the form called *Cacalia lutea*, Hort.) heads: lvs. lance-oblong or ovate-lanceolate, clasping the st., remotely crenate-dentate: involucre-scales much shorter than the florets. Probably tropics of New World. H.F. 7:50.—This much-named annual is one of the commonest garden fls. It is of the easiest cult. in any good soil. Blooms from July until frost, if sown as soon as weather is settled. Two species are sometimes recognized in this variable group,—*E. sagittata*, DC., with involucre shorter than the fls., and *E. sonchifolia*, DC., involucre as long as the fls.

*E. purpurea*, Cass. (*E. sonchifolia*, DC., not Hort. *Cacalia sonchifolia*, Linn. *Senecio sonchifolius*, Moench). Radical lvs. often more or less lyrate, st.-lvs. broader and clasping, the heads fewer in the cluster and the involucre-scales nearly as long as the florets. Apparently not in cult. in this country.

L. H. B.

**EMMENÁNTHE** (Greek, *enduring flower*; the persistent corollas retain their shape when dry). *Hydrophyllaceæ*. A half-dozen low annual herbs from western North America, of which the most interesting species was introduced to cultivation in 1892, under the name of California yellow- or golden-bells.

Diffuse, depressed or erect: lvs. mostly alternate: fls. yellow or cream-color, the corolla campanulate and persistent; corolla-lobes 5; stamens 5; style 2-cut. The species named below belongs to a section of the genus, with calyx-lobes broader downward, and coarsely pitted seeds. All the others have the calyx-lobes broader upward and the seeds more or less wrinkled transversely.

**penduliflora**, Benth. **CALIFORNIA YELLOW- or GOLDEN-BELLS**. Somewhat sticky, with long or short soft hairs: lvs. pinnatifid, lobes numerous, short, somewhat toothed or sharply cut; ovules about 16; seeds 1 line long. Calif. G.C. III. 11:339.—It grows 9–12 in. high, forming bushy plants, each branch loaded with broadly bell-shaped, pendulous, unwithering fls., about  $\frac{1}{2}$  in. long, of creamy yellow. The general effect of a branch suggests the lily-of-the-valley, but the foliage is pinnatifid.

WILHELM MILLER.

**EMMENÓPTERYS** (Greek, *persistent*, and *wing*; referring to the wing-like calyx-lobe, persistent on the fruit). *Rubiaceæ*. Ornamental tree grown for its large leaves and the handsome flowers.

Deciduous: lvs. opposite, petioled, with caducous stipules, entire: fls. in many-fld. terminal panicles; calyx small, 5-parted, deciduous, in some fls. 1 lobe leafy and changed into a petioled, oblong, obtuse whitish lf. persistent on the fr.; corolla campanulate-funnelform, tomentulose outside, with a narrow tube and 5 ovate lobes pubescent inside; stamens 5, included; ovary inferior, 2-celled; style filiform, not exceeding

the stamens: fr. a spindle-shaped 2-celled caps., with numerous irregularly winged seeds.—One species in Cent. China. A tall tree, with large elliptic lvs. and showy yellow fls. in many-fld. dense terminal panicles. It will succeed in warmer temperate regions only and is yet little known in cult., as it has been only recently intro. Prop. is by seeds and possibly by softwood cuttings under glass.

**Hénryi**, Oliver. Tree, to 40 ft., quite glabrous: lvs. chartaceous, elliptic, acute, cuneate at the base, entire, 4–6 in. long; petiole 1–2 in. long: fls. in many-fld. panicles, yellow, about 1 in. long: caps. spindle-shaped, about  $1\frac{3}{4}$  in. long, often at the apex with a persistent enlarged wing-like calyx-lobe  $1\frac{1}{2}$ –2 in. long on a petiole of equal length. Cent. China. H.I. 19:1823.

ALFRED REHDER.

**ÉMPETRUM** (Greek, *en*, in, *petros*, rock; growing often on rocks). *Empetraceæ*. **CROWBERRY**. Ornamental low shrubs sometimes grown for the evergreen foliage and attractive fruits.

Leaves linear-oblong, obtuse, thick: fls. dioecious or monœcious, axillary, 1–3, nearly sessile; sepals and petals 3; stamens 3, exserted; ovary superior, 6–9-celled with as many stigmas on a short and thick style: fr. a 6–9-seeded drupe.—Five species through the northern hemisphere in mountainous and arctic regions, also in Chile, antarctic Amer. and Tristan da Cunha.

The crowberries are hardy, evergreen, densely branched, prostrate or creeping, heath-like shrubs, with small, crowded leaves, inconspicuous purplish flowers, and globose, red or black, edible berries. They grow best in moist, sandy or peaty soil, and are especially handsome for rockeries. Propagated usually by cuttings of nearly ripened wood in late summer under glass.

**A. Branchlets and margin of expanding lvs. glandular, the latter not tomentose.**

**nigrum**, Linn. Lvs. linear to linear-oblong, divergent, soon reflexed, glabrous or nearly so, entire,  $\frac{1}{6}$ – $\frac{1}{4}$  in. long: fls. purplish: fr. black, about  $\frac{1}{2}$  in. diam. April, May; fr. in Aug., Sept. N. Eu., N. Asia., in N. Amer. south to N. H., N. Y., Mich. and N. Calif. B.B. (ed. 2) 2:479. S.E.F. 8:1251.

**AA. Branchlets and margins of expanding lvs. white-tomentose.**

**atropurpureum**, Fern. & Wiegand (*E. nigrum* var. *andinum*, Fern., not *E. andinum*, Philippi. *E. nigrum* var. *purpureum*, Auth., not DC.). Trailing: lvs. linear-oblong, soon loosely divergent, rarely becoming reflexed, those of the leading shoots  $\frac{1}{6}$ – $\frac{1}{4}$  in. long: fr. red to purplish black, opaque,  $\frac{1}{6}$ – $\frac{1}{2}$  in. across. Gulf St. Lawrence to Maine and N. H.

**Eamesii**, Fern. & Wiegand (*E. nigrum* var. *purpureum*, Auth., not DC. *E. rubrum*, La Pylaie, not Vahl). Lvs. linear-oblong, crowded, ascending, becoming slightly divergent, those of the leading shoots  $\frac{1}{2}$  in. or less long: fr. pink or light red, becoming translucent,  $\frac{1}{2}$  in. or less across. S. Labrador, Newfoundland, E. Que.—Very handsome in fruit.

*E. rubrum*, Vahl (*E. nigrum* var. *rubrum*, DC.). Closely related to *E. Eamesii*. Lvs. less crowded, spreading, somewhat larger. Antarctic Amer., Tristan da Cunha. B.R. 1783.

ALFRED REHDER.

**ENCÈLIA** (Christopher Encel in 1577 wrote a book on oak galls). *Compositæ*. Herbs or sub-shrubs, one or two of which have been sparingly introduced for planting in the southern parts of the United States.

Rather showy plants with mostly yellow-rayed naked-stalked heads (rays now and then absent), and yellow or brownish disk: lvs. alternate or opposite, entire, toothed or lobed, often white-tomentose: rays neutral, disk-fls. perfect; pappus none or an awn or scale for each margin or angle of the achene.—About 30 species, Utah and Calif. to Chile.

*californica*, Nutt. Woody at base, 2-4 ft. high, strong-scented, rather hoary, or becoming green: lvs. 1-2 in. long, ovate to broadly lanceolate, usually entire, indistinctly 3-ribbed from the base, abruptly stalked: heads  $2\frac{1}{2}$  in. across, the golden yellow rays numerous, 2-4-toothed: seeds obovate, with long, silky hairs on the callous margins and a shallow notch at the tip. Calif., Ariz.

*adenóphora*, Greenm. Stout almost woody herb, 3-6 ft., sometimes 10 ft., glandular-hairy throughout: lower lvs. opposite, stalked, ovate or deltoid,  $2\frac{1}{2}$ -4 in. long, 3-nerved; upper lvs. gradually smaller: fls. cymose, the rays pale yellow, sometimes tinged with orange. Autumn. N. Mex.—Not hardy north of Washington, D.C.

N. TAYLOR.†

**ENCEPHALÁRTOS** (Greek combination, alluding to the bread-like interior of the trunk). *Cycadaceæ*. Excellent cycads from tropical and southern Africa, grown chiefly for their evergreen foliage.

The species are probably 20 or more, allied to *Dioon* and *Macrozamia*; with *Stangeria*, they constitute the peculiarly African representatives of the family. They are trees with stout cylindrical often fleshy trunks, and a terminal crown of stiff mostly spiny pinnate long lvs. or fronds: fls. diceious, in cones; staminate cone oblong, ovoid or cylindrical, the scales in many series, imbricate, thick and often rough, broadly or elongate-cuneate, with anthers on the under surface; pistillate cone ellipsoid or oblong, thick, the scales numerous in many series and imbricated, peltate, with the ovule beneath. For differences between this and related genera, see Vol. I, p. 120. From *Dioon* it is distinguished by its pinnate rather than pinatifid lvs., and from *Cycas* by straight rather than circinnate segms. in veneration, as well as by technical features of cones. These plants are specially suited for large conservatories, the fronds being not easily injured. They should succeed outdoors S. The trunks of some kinds grow only a few inches in many years. Most kinds prefer a sunny, tropical house, but *E. brachyphyllus* and perhaps others may be grown in a cool greenhouse if kept a little dry in winter. The cones are always interesting and often very decorative. Those of *E. villosus* are twice as large as a pineapple, orange-yellow, half revealing the scarlet frs. They are prop. by seeds; also by offsets or suckers. Some other cycads frequently produce seed in conservatories, but *Encephalartos* seldom does, and plants are, therefore, usually imported. Dry trunks, weighing frequently 50-75 lbs. have been received from S. Afr. They often remain dormant for a year or more, and do not make ornamental specimens for two or more years. They are slow-growing, except in very warm houses. They like a strong, loamy soil. While making new growth they need plenty of water. See *Cycas*.

The woolliness of the stem and leaf-segments varies with the age of the plants and of the leaves. The pith and central portion of the cones of some species form an article of food among the Kafirs, hence the common name of Kafir bread. The most widely known species in cultivation are *E. villosus*, *E. Altensteinii* and *E. pungens*. Though very handsome cyads, they are by no means popular. They require much room for best results.

In the following descriptions "rachis" refers to the midrib of the leaf on which the leaflets or segments are borne, and "petiole" means the part of the leaf below where the leaflets begin.

A. Lfts. toothed (sometimes entire in the first).

B. Petiole 4-angled: foliage glaucous.

*hórridus*, Lehm. Trunk short and stout, woolly or not: lvs. to 6 ft., reflexed at top; lfts. opposite or alternate,

lanceolate, mostly entire, sometimes toothed, with a sharp spine at the apex. Var. *glaúca*, is presumably more glaucous than the type. B.M. 5371. There is a var. *trispinosus*.

BB. Petiole sub-cylindrical: foliage not glaucous.

*Áltensteinii*, Lehm. Trunk stout, not woolly: lvs. 2-6 ft.; lfts. about 6 in. long and 1 in. broad, oblong-acuminate, paler beneath, edges and apex spiny; petioles swollen at base; lfts. mostly opposite, lanceolate. B.M. 7162-3. G.C. II. 6:392, 393, 397; III. 2:281; 12:489-493; 40:206 (showing a specimen in Cape Colony over 100 years old, with a high trunk and an offshoot over half way up). G. 7:516.

*villósus*, Lehm. Trunk short and thick, woolly and scaly, 6 ft.: lvs. to 6 ft.; lfts. very numerous, opposite or alternate, linear-lanceolate, spiny-toothed and pointed. B.M. 6654. R.H. 1897:36. G.C. II. 1:513; 3:400; 7:21; 13:181.

1394. *Encephalartos cycadifolius*.

AA. Lfts. not toothed (except in young lvs. of the last one).

B. Foliage glaucous.

*Léhmännii*, Lehm. (*Cycas Léhmännii*, Hort.). Trunk not woolly: rachis and petiole obtusely 4-angled; lfts. nearly opposite, narrowly or broadly lanceolate, to 7 in. long, rarely 1-toothed, with brown spine at apex. Gt. 1865:477.

BB. Foliage not glaucous.

c. Apex of lfts. mostly obtuse, pointless.

*longifólius*, Lehm. Trunk not woolly, at length tall: rachis and petiole 4-cornered but flattish above; lowest lfts. often 1-3-toothed, margin somewhat revolute: wool soon vanishing from the rachis and lfts. S. Afr. G.W. 5, p. 404. Var. *revolutus*, Miq., has the margins more distinctly revolute. Var. *angustifólius* has narrower, flat lfts. Var. *Hoòkeri*, DC., has narrowly lanceolate lfts., not glaucous but intense green, and rachis not woolly. B.M. 4903, erroneously named *E. caffer*, is referred to this place, though the lfts. are distinctly pointed in the picture.

cc. Apex of lfts. always strong-pointed.

D. Form of lfts. linear.

*cycadifólius*, Lehm. (*E. Friderici-Guilielmi*, Lehm. *E. cycadifólius* var. *Friderici-Guilielmi*, Rod.). Fig. 1394. Trunk nearly globular, several inches in diam., woolly at first: rachis and petiole ashy-pubescent;

lfts. opposite and alternate, linear, margin revolute. I.H. 29:459. G.F. 4:209 (adapted in Fig. 1394). G.W. 10, p. 377 (as *E. cycadifolius* var. *Friderici-Guilielmi*).

**püngens**, Lehm. (*Zamia püngens*, Ait.). Rachis and petiole glabrous; lfts. long-linear, dark green, rigid, flat, striated beneath, margin not revolute. Var. **glauca** is also sold.

DD. *Form of lfts. lanceolate.*

**cáffer**, Miq. (*E. cáfra*, Hort.). Trunk to 18 ft. and 1 ft. or more diam.: lvs. to 4 ft., very stiff, recurved; petiole 3-angled; rachis glabrous; lfts. alternate, narrower at the base, twisted, the younger ones with 1 or 2 teeth, to 6 in. long. R.H. 1869, p. 233. Not B.M. 4903, which is *E. longifolius* var. *Hookeri*.

Var. **brachyphýllus**, DC. (*E. brachyphýllus*, Lehm.). Rachis and blades of the lower lfts. spidery pubescent: male cones sessile instead of peduncled. The pinnæ are erect, and longer and narrower than in *E. cáffer*.

*E. Bárteri*, Carr. St. short, about 1 ft. high and to 9 in. diam.: lvs. to 5 or 6 ft. long, and 10 in. broad, erect or suberect; petiole and rachis with a gray tomentum that falls off; lfts. about 80 pairs, linear-lanceolate, sharp at the apex, few-toothed: male cone to 9 in. long, pale; female cone about 8 in. long, oblong-ellipsoid, dark olive. W. Trop. Afr. B.M. 8232.—*E. Ghellinckii*, Lem. Spineless: trunk stout, woolly-sealy: lvs. 3-4 ft., erect-spreading; pinnæ very narrow-linear, densely tomentose. S. Afr. I.H. 15:567.—*E. Hildebrandtii*, A. Br. & Bouché. Trunk cylindrical: lvs. pinnate, with numerous lanceolate toothed pinnæ which become 3-parted scales toward the end of the lf., woolly at least at first. Trop. Afr. G.C. III. 27:120. R.B. 29:196. G.W. 10, p. 210. An attractive species.—*E. Laurentianus*, Wildem. Large, the st. reaching 30 ft. or more and 2½ ft. diam.: lvs. often over 20 ft. long; lower lfs. small, 3-toothed; middle lfts. lanceolate, 12-16 in. long and 2 in. broad, spiny on both edges and at the apex. Congo. G.C. III. 35:370. Named for Professor Laurent.—*E. Lemarinellianus*, Wildem. & Dur. St. 3-7 ft.; lvs. to 3 ft. or more; petiole shaggy; lfts. 18-60 on each side, rigid, coriaceous, glaucous, lanceolate, the edge slightly recurved, more or less spiny: male cone greenish, subcylindrical; female cone thick, green turning to salmon-color, short-peduncled, the scales triangular. Congo. Named for Capt. Lemarinell. G.C. III. 35:371. R.H. 1904, p. 59.—*E. Woodii*, Hort. Allied to *E. Altensteinii*: st. 18 in. high and 8 in. thick, bearing about 25 lvs. which are gracefully curved and reach 5 ft.: lfts. 8 in. long and 2 in. broad, spiny-toothed, the broadest ones pinnatifid. Zululand. G.C. III. 43:282. R.B. 34, p. 193. L. H. B.†

ENCHOLIRION: *Vriessia*.

**ENCHYLÈNA** (name alludes to the soft or juicy character of the berry-like fructification). *Chenopodiaceæ*. One procumbent or wide-branched very small-leaved shrub from Austral. recently intro. by U. S. Dept. Agric., and thriving well at the University of California. *E. tomentosa*, R. Br., grows 3 ft. or more high and makes a mass many feet across; branches mostly woolly or silvery: lvs. alternate, linear, usually under ½ in. long; fls. solitary in the axils, bracted, very small, perfect; perianth urn-shaped to globular, with

5 short teeth that close over the fr.; stamens 5, somewhat exserted: fr. inclosed in the perianth, which becomes red or yellow, fleshy and berry-like and the size of a small pea. The Australian aborigines are said to eat the berries in great quantities. The plant endures drought, and it is eaten by sheep when other herbage becomes scarce. The procumbent habit and the enduring color suggest its use in landscape work in dry mild climates.

ENCKËA: *Piper*.

**ENDIVE** (*Cichorium Endivia*). *Compósitæ*. A leaf-salad plant. See *Cichorium*.

Until recently endive has been almost unknown in American home gardens, but it is gradually receiving favor with salad-lovers. Although more frequently a product of the amateur, during August and September, and possibly later, it is now freely offered in the larger markets. It is especially the people of foreign descent who grow, buy and use endive. In the hot weather of summer and fall, when lettuce plants are more likely to produce seed-stalks than good solid heads, endive, although of somewhat bitter flavor when unbleached, makes a good and acceptable substitute for lettuce as a salad plant. In the unbleached state it may even be used for "greens."

The requirements as to culture are simple, as the plant succeeds well on any ordinary well-enriched garden soil. Seed may be sown in the open ground as early as June, and as late as August, the rows to be a foot apart and the plants to be thinned early to a foot apart in the row; or seed may be started in flats and the young seedlings transplanted to open ground. The latter is the better way when the ground is very dry. In extreme cases, it may be advisable for the home gardener to grow his seedlings in flats and pot them off in thumb-pots to become well rooted. This gives a chance to grow good plants, while waiting for a rain to moisten the open ground. To be tender, the plants should be forced into strong and succulent growth by high feeding and the free use of the hoe. It is a waste of effort to plant endive on poor land that is deficient in humus, or naturally dry and exposed.

The originally bitter flavor becomes pleasant and acceptable when the leaves or hearts are well blanched. The blanching is accomplished by tying the outer leaves over the heart with bast (Fig. 1395), or by placing a big flower-pot over each plant, or by setting boards, say 10 inches wide, on edge along each side of the row, in inverted V shape, and in somewhat the same fashion as for blanching celery, except that no opening is left on top. The light should be excluded from the hearts as much as possible. In any of these ways endive may be well blanched in about three weeks, and will come out with inner leaves showing a delicate whitish or creamy color, and being crisp, tender and of pleasant flavor.

If to be kept for winter use, sow the seed of Green Curled endive in August, or set the plants early in September; then take up the full-grown but as yet unblanched plants with a ball of earth adhering to the roots, and store them in a root-cellar as is done with celery. If kept in the dark, they will soon bleach and be ready for use.

Green Curled has long been the favorite variety in our markets and gardens. Its narrow curled leaves make the well-blanched plant far more attractive to the eye than the wider and plain leaves of Broad-Leaf. The latter, however, is gaining on the other in both growers' and consumers' favor. This is the only practical difference between the two varieties. The catalogues of European seedsmen list and describe several additional varieties, such as the Moss Curled and Rouen, none of which is often met with in American gardens. A few fungi and the spinach insects sometimes attack the plant.

T. GREYNER.

1395. Green curled endive tied up for blanching.

**ENGELMANNIA** (Dr. Geo. Engelmann, eminent botanist of St. Louis, died 1884). *Compositæ*. One yellow-fl. herb, *E. pinnatifida*, Torr. & Gray, allied to Parthenium and Silphium, Kans. to La., Ariz. and Mex., that is likely to be planted in wild gardens. It grows a foot or two high, in dry places, from a stout perennial root, branching above, hirsute, with alternate and radical deeply pinnatifid lvs., and corymbose heads of golden yellow fls. on slender and naked peduncles: involucre hemispherical, somewhat double; receptacle flat and chaffy; ray-fls. 8-10, pistillate and fertile, the rays  $\frac{1}{2}$  in. or more long; disk-fls. perfect and sterile: achene obovate, wingless, ribbed, with a persistent pappus-crown.

**ENKIANTHUS** (Greek *pregnant and flower*, referring to the colored involucre which subtends the flowers of *E. quinqueflorus*, giving the appearance of small flowers springing from a larger flower). Also written *Enkianthus*. *Ericaceæ*. Ornamental woody plants, chiefly grown for their handsome flowers and the brilliant autumnal tints of the foliage.

Deciduous, rarely evergreen shrubs with whorled branches: lvs. alternate, usually serrulate, crowded toward the end of the branchlets: fls. in terminal umbels or racemes; sepals 5, small; corolla campanulate or urceolate, usually 5-lobed; stamens 10; anthers 2-awned at the apex, opening with short slits: fr. a dehiscent caps.; cells 1- to few-seeded; seeds 3-5-winged or -angled.—About 10 species in China and Japan, Cochinchina and Himalayas. Closely related to Pieris and Zenobia; chiefly distinguished by the few- or 1-seeded cells of the caps. and the winged or angled seeds.

These are charming ornamental shrubs, with bright green, medium-sized leaves turning brilliant colors in autumn and with handsome white, red or yellow-and-red, drooping flowers appearing in spring; the flowers are not of the showy kind, but very graceful and of distinct appearance. Most of the cultivated species, as *E. campanulatus*, *E. cernuus*, *E. perulatus* and *E. subsessilis*, have proved hardy in Massachusetts; they seem to grow well in any well-drained humid soil, but probably are impatient of lime, as are most *Ericaceæ* and in limestone regions should be grown in specially prepared beds of peaty soil. Propagation is by seeds sown in spring, by cuttings of ripe wood under glass in spring, or by greenwood cuttings in summer; also by layers.

A. Fls. urceolate, gibbous at the base, white.

*perulatus*, Schneid. (*E. japonicus*, Hook. f. *Andrómæda perulata*, Miq.). Shrub, to 6 ft.: lvs. petioled, obovate to elliptic-ovate, acute, sharply appressed-serrulate, glabrous and bright green above, pubescent on the veins below, 1-2 in. long: fls. in drooping umbels, slender-pedicelled; corolla urceolate, with 5 revolute lobes and with 5 sacs at the base,  $\frac{1}{3}$  in. long: caps. oblong-ovoid, about  $\frac{1}{3}$  in. long, on straight pedicels. May. Japan. B.M. 5822. G.C. III. 21:357. R.H. 1877, p. 467. S.I.F. 2:62.—The foliage turns yellow and partly scarlet in autumn.

AA. Fls. campanulate, not gibbous at the base, usually red or yellow-and-red.

*campanulatus*, Nichols. (*Andrómæda campanulata*, Miq.). Fig. 1396. Shrub, to 15 or occasionally to 30 ft.: lvs. petioled, elliptic or rhombic-elliptic, acute or acuminate, sharply appressed serrulate, glabrous except few scattered bristly hairs, particularly on the veins below,  $1\frac{1}{2}$ -3 in. long: fls. slender-pedicelled, in drooping, 8-15-fl. puberulous racemes; corolla with short obtuse upright lobes, yellowish or pale orange, veined darker red, nearly  $\frac{1}{2}$  in. long: caps. oblong-ovate on pendulous stalks turned upward at the apex. May. Japan. B.M. 7059. Gn. 75, p. 287. G. 29:361. Gt. 22:747. M.D.G. 1900:550. S.I.F. 2:62.—This is one

of the handsomest species and the strongest grower; the peculiar coloring of the gracefully drooping fls. is very attractive; the foliage turns brilliant red in autumn.

*cernuus*, Makino (*E. Meistèria*, Maxim. *Andrómæda cernua*, Miq.). Shrub, to 15 ft.: lvs. short-petioled, obovate or rhombic-obovate, acute or obtusish, crenately serrate, bright green above, lighter below and pubescent on the veins, 1-2 in. long: fls. in pendulous racemes, slender-pedicelled; corolla with irregularly lacinate limb, about  $\frac{1}{2}$  in. long, white in the type: caps. on pendulous stalks turned upward at the apex. May. Japan. Var. *rubens*, Makino. Fls. red.—Only the red-fl. variety seems to be in cult. and is a very distinct-looking handsome shrub.

*E. chinensis*, Franch. (*E. himalaicus* var. *chinensis*, Diels). Allied to *E. campanulatus*. Lvs. quite glabrous, more crenately serrate: racemes glabrous; corolla yellow and red, with darker red lobes. Cent. and W. China. J.H.F. 1900: 212.—*E. deflexus*, Schneid. (*E. himalaicus*, Hook. f. & Thoms.). Closely related to *E. campanulatus*. Lvs. elliptic-ovate to elliptic-lanceolate, acute, slightly serrate, margin and petioles red while young: racemes many-fl.; corolla yellow, striped dark red, with darker lobes. Himalayas. W. China. B.M. 6460.—*E. himalaicus*, Hook. f. & Thoms.—*E. deflexus* and *E. chinensis*.—*E. nikoensis*, Makino = *E. subsessilis*.—*E. quinqueflorus*, Lour. (*E. reticulatus*, Lindl.). Lvs. elliptic, long-petioled, entire, persistent: fls. about 5, in umbels, subtended by colored bracts, drooping; corolla campanulate, scarlet. S. China, Cochinchina. B.M. 1649. B.R. 884, 885. L.B.C. 12:1101. P.M. 5:127. R.H. 1849:221. H.F. 1859:101. Tender. Var. *serrulatus*, Wilson (*E. serrulatus*, Schneid.). Lvs. deciduous, membranous, finely serrulate: fls. smaller. Cent. and S. W. China.—*E. reticulatus*, Lindl.—*E. quinqueflorus*.—*E. serrulatus*, Schneid.—*E. quinqueflorus* var. *serrulatus*.—*E. subsessilis*, Makino (*E. nikoensis*, Makino). Allied to *E. perulatus*. Lvs. short-petioled, elliptic or obovate: fls. in pendulous racemes, small, white,  $\frac{1}{3}$  in. long. June. Japan. S.T.S. 1:25. S.I.F. 2:62.—This is the least attractive in bloom, but the autumnal tints of the foliage are as beautiful as in the other species.

ALFRED REHDER.

**ENNEALOPHUS** (name refers to the 9 crests on the style). *Iridaceæ*. A very recently described genus of one species, *E. amazonicus*, N. E. Br., differing from *Tigridia* in the 3 style-branches being 3-crested rather than bifid or subulate. The perianth-segms. are free, unequal and clawed, the exterior ones much the larger, the blades of all of them more or less reflexed; stamens 3, the filaments connate into a tube. The bulb of the single known species is about 1 in. long, ovoid: lvs. linear-lanceolate, about 4, the upper one about 2 in. long and the others 6-12 in.: fls. about  $1\frac{1}{2}$  in. across, blue-violet with pale brown claws and a white spot at the base of the blade of the inner segms. Brazil; apparently not in the trade.

**ENTADA** (a Malabar name). Syn. *Pusætha*. *Leguminosæ*. Tropical woody spineless climbers.

Leaves bipinnate, often cirriferous: fls. not papilionaceous, white or yellow, in slender spike-like racemes which are solitary or paniced; calyx campanulate, shortly 5-toothed; petals 5, free or somewhat coherent; stamens 10, free, short-exserted: pod straight or arcuate, flat-compressed, jointed, the joints separating and leaving a continuous border.—Perhaps 20 species of high climbers in Afr. and Amer. The genus is remark-

1396.  
*Enkianthus*  
*campanulatus*.  
( $\times \frac{1}{2}$ )

able for the jointed pods, which sometimes reach several feet in length. Two of the American species are mentioned as planted in S. Fla. Some of the species yield "sea beans" (G. F. 7:503).

**polystachya**, DC. At length tendrill-bearing: pinnæ in 4-6 pairs; lfts. in 6-8 pairs, oblong, rounded at apex, beneath glabrous or puberulent; racemes in terminal panicles: pod oblong, straightish, reaching 1 ft. in length. W. Indies to Venezuela and Guiana.—Makes a rapid growth.

**scândens**, Benth. Climbing to a great height, tendrill-bearing, the sts. terete: pinnæ 1 or 2 pairs; lfts. 2-5 pairs, coriaceous, oblong or elliptic, usually unequal-sided, glabrous or nearly so beneath; racemes solitary or twin: pod twisted, sometimes 8 ft. long. W. Indies, Afr., Asia, Pacific Isls. G.C. II. 15:430.—Seeds 2 in. across, dark brown or purple, handsome, used in the making of trinkets and small receptacles. Lvs. long-stalked, the rachis commonly ending in a tendrill. L. H. B.

**ENTELEËA** (Greek, *complete*; the stamens all fertile, a distinguishing feature). *Tiliaceæ*. A shrub or small tree from New Zeal., intro. in S. Calif. Lvs. large, alternate, 5-7-nerved, cordate at base, toothed or crenate, stellate-pubescent: fls. white, 1 in. across, in terminal cymes; sepals 4-5; petals 4-5; stamens numerous, free; ovary 4-6-celled; cells many-ovuled; style simple: fr. a globose bristly loculicidal caps.

**arborëscens**, R. Br. Attaining 20 ft.: the heart-shaped outline of the lf. broken on each side, about two-thirds of the way toward the tip, by a projection or lobe  $\frac{1}{2}$  in. long or nearly as long as the tip of the lf.; blade 6-9 in. long, 4 in. wide, doubly serrate. New Zeal. B.M. 2480.—Eaten by horses and cattle in New Zeal. Allied to *Sparmannia*, *Aristotelia* and *Elæocarpus*. L. H. B.

**ENTEROLÔBIUM** (name refers to the *intestine-form* pods). *Leguminosæ*. Tropical trees.

Unarmed: lvs. bipinnate, the pinnæ and lfts. many: fls. not papilionaceous, greenish, in large heads or clusters; calyx campanulate, shortly 5-toothed; corolla 5-toothed, somewhat trumpet-shaped, the petals connate part way; stamens many, connate at base into a tube, exerted, purple or white: legume broad, circinate, attached at or near the middle, restricted between the large seeds, leathery, pulpy.—About a half-dozen species in the American tropics, 2 of which have been intro. in S. Calif.

A. *Pod bent back in a complete circle.*

**cyclocârpum**, Griseb. Tall tree, glabrous: pinnæ in 4-9 pairs; lfts. in 20-30 pairs, unequal-sided, oblong, pointed; the petiole with glands between bottom and top pinnæ: stamens white. Cuba, Jamaica, Venezuela.

AA. *Pod forming half or two-thirds of a circle.*

**Timbouva**, Mart. Said to be a fine tree: pubescent or glabrous, glaucous: pinnæ 2-5-pairs; lfts. 10-20 pairs, falcate-oblong, mostly acute: pod coriaceous and indehiscent, reniform, fleshy within; seed elliptic. L. H. B.

**EOMËCON** (Greek, *eastern poppy*). *Papaveracææ*. Herbaceous perennial, with white flowers on a slender-branched scape.

Rhizomatous, with radical lvs., glabrous: "monotypic, intermediate between *Stylophorum* and *Sanguinaria*, differing from both in the scapose habit, racemose fls. and sepals confluent in a membranous, boat-shaped spathe, and further from *Stylophorum* in the form of the lvs. and color of the fls., and from *Sanguinaria* in the 4 petals and elongate style" (Hooker).

**chionántha**, Hance. Rootstock creeping, ascending, full of yellow sap: lvs. all from the root; stalks twice as long as the blades; blades 3-6 in. long, heart-shaped, concave, broadly sinuate, rounded at the apex, bright

pale green above, almost glaucous beneath: scape 1 ft. or more high, reddish; fls. 2 in. across, white; petals 4. Spring; hardy near New York City. E. China. B.M. 6871. WILHELM MULLER.

EOPËPON: *Trihcosanthes*.

**ÉPACRIS** (Greek-made name, *upon the summit*; referring to their habitat). *Epacridacææ*. Heath-like shrubs of Australia and New Zealand, of which half a dozen or less are grown as cool greenhouse pot-plants.

Leaves small and entire, usually sharp-pointed, sessile or short-stalked, scattered or sub-opposite: fls. small and axillary, short-stalked, the flowering sts. being elongated leafy spikes, regular and perfect; calyx bracteate; corolla tubular, 2-toothed, white or shades of purple and red; stamens 5; ovary 5-loculed, ripening into either a fleshy or capsular fr. Distinguished from *Erica* by the bracteate or scaly calyx, and the anthers opening by slits rather than pores.—About 40 species. In the Old World, epacris are prized by those who grow heaths, and many good varieties are known. They bloom in early spring or late winter. The varieties of *E. impressa* may be flowered for Christmas; perhaps others may be so treated. A carnation house, 50-55°, suits them well. There are double-fl. forms.

A. *Corolla-tube decidedly longer than the calyx.*

**impressa**, Labill. Three ft., erect, twiggy, downy: lvs. horizontal or deflexed, narrow-lanceolate and sharp: fls. rather large (often  $\frac{1}{2}$  in. long), tubular, pendent, on very short stalks, red or white. B.M. 3407. There are many forms: var. **parviflora**, Lindl., B.R. 25:19; *E. campanulata*, Lodd., with broader fls., L.B.C. 20:1925; *E. ceræflora*, Graham. B.M. 3243; *E. nivâlis*, Lodd., snow-white, L.B.C. 19:1821. B.R. 1531; *E. variabilis*, Lodd., blush, L.B.C. 19:1816; var. **longiflora**, Cav., (*E. miniata*, Lindl. *E. grandiflora*, Willd.). Sts. woolly, straggling: lvs. ovate-pointed or cordate-pointed, sessile or nearly so, many-nerved: fls. long (nearly 1 in.), red at base and white at the limb, cylindrical. B.M. 982. B.R. 31:5.—Handsome. Var. **splendens**, Hort., has brighter colors.

AA. *Corolla-tube shorter than the calyx or only as long as it.*

B. *Lvs. acute or acuminate.*

**acuminata**, Benth. Lvs. ovate, acuminate, clasping, ascending: fls. small, red nearly sessile in the upper axils; corolla-tube not exceeding the calyx; sepals broad, ciliate.—Little known in U. S. outside of botanic gardens, but of considerable worth.

**breviflora**, Stapf. (*E. hetronema*, Hook.). A graceful shrub, 1 ft., with many wary branches, naked below, with many lvs. above: lvs. divaricate on upper part of st., reflexed below, elliptic-ovate, 3-6 lines long, sharp-pointed: fls. spicate at the ends of the branches, white; bracts and sepals whitish. New Zeal. Flowers in May in England. B.M. 3257.

**purpurascens**, R. Br. Lvs. ovate-acuminate, trough-shaped, tipped with a long curved point or spine: fls. short, the calyx nearly equaling the corolla, white or pinkish. There is a double-fl. form. L.B.C. 3:237. G.C. II. 5:340.—Probably identical with *E. pulchella*, Cav.

BB. *Lvs. very obtuse.*

**obtusifolia**, Smith. An erect, much-branched shrub 1-3 ft. tall, the branches usually hairy: lvs. small, elliptic or linear, thick and obtuse: fls. small, white, in axillary racemes which are more or less one-sided. L.B.C. 3:292.

Other trade names are: *E. ardentissima*. Fls. crimson.—*E. hyacinthiflora* var. *candidissima*, white, early, and var. *fulgens*, pink.—*E. hybrida superba* is merely a catalogue name for mixed kinds of Epacris.—*E. rubella*. Fls. bright red.—*E. salmonea* (?)

N. TAYLOR.†

**EPHÉDRA** (ancient Greek name, used by Pliny for the horse-tail). *Gnétaceæ*. Woody subjects, rarely cultivated; usually found only in botanical collections, although the scarlet fruits of some species are very attractive.

Usually low much-branched shrubs, often procumbent and sometimes climbing, the green branches resembling much those of *Equisetum*, bearing minute, scale-like, sheathing lvs. in distant pairs or whorls; fls. dioecious, in small aments, forming usually peduncled axillary clusters; staminate fl. with a 2-4-lobed perianth and with the 2-8 stamens united into a column; pistillate fl. with an urceolate perianth, including a naked ovule, developing into a nutlet; in some species the bracts of the ament become fleshy, and form a berry-like syncarp.—About 30 species from S. Eu., N. Afr., Asia and in Trop. Amer. Latest monograph by O. Stapf, in Denkschr. Akad. Wissensch. Wien., vol. 56 (1889), (in German and Latin). Curious-looking, usually low shrubs, with pale green apparently leafless branchlets, much resembling those of the horse-tail and with inconspicuous fls., but fr. in some species decorative, berry-like and scarlet. They are but rarely grown, and most of them are tender; half-hardy N. are *E. distachya*, *E. foliata*, *E. nevadensis*, *E. trifurca*. They can be used for covering dry, sandy banks or rocky slopes. Prop. is by seeds or by suckers and layers.

*E. altissima*, Desf. Climbing shrub, to 20 ft., green: lvs. to 1 in. long: aments paniculate or solitary: fls. with 2-3 stamens; pistillate fls. 1-2: fr. berry-like, ovoid,  $\frac{1}{2}$  in. long, scarlet. N. Afr. B.M. 7670. G.C. III. 7: 792.—*E. distachya*, Linn. (*E. vulgaris*, Linn.). Low, often procumbent, 1-3 ft., pale or bluish green: lvs. one-twelfth in. long: aments usually clustered, staminate oblong; fls. with about 8 stamens, pistillate 2-fld.: fr. berry-like. S. Eu., W. Asia. R.F.G. II. 1: 809. Var. *monostachya*, Stapf. Aments usually solitary.—*E. foliata*, Boiss. (*E. kokanica*, Regel). Procumbent or erect, to 15 ft., bright or bluish green: lvs. to 1 in. long: aments usually clustered, ovate; staminate fls. with 3-4 sessile stamens; pistillate 2-fld.: fr. berry-like. W. Asia.—*E. kokanica*, Regel=*E. foliata*.—*E. nebrodensis*, Tineo. Erect, with rigid, pale green branches: lvs.  $\frac{1}{2}$  in. long: aments solitary or few; staminate globular; pistillate 2-fld.: fr. berry-like. Medit. region to Himalayas.—*E. nevadensis*, Wats. Erect, 2-3 ft., with pale or bluish green branches: lvs.  $\frac{1}{2}$  in.: aments usually solitary; staminate ovate, 6-8-fld.; pistillate 2-fld.: fr. dry, with ovate bracts. Calif., New Mex.—*E. trifurca*, Torr. Erect, with rigid, yellowish or pale green branches: lvs. in 3's, connate, about  $\frac{1}{4}$  in. long: aments solitary; pistillate 1-fld.: fr. dry, the roundish bracts with transparent margins. Ariz. to Colo.—*E. vulgaris*, Linn.=*E. distachya*.

ALFRED REHDER.

**EPICÁTTLEYA** (compounded of *Epidendrum* and *Cattleya*). *Orchidaceæ*. A genus established to contain hybrids between *Epidendrum* and *Cattleya*.

The following are some of these: *E. balarucensis* (*C. labiata* × *E. eburneum*).—*E. cándida* (*C. Skinneri* × *E. nocturnum*).—*E. decipiens* (*C. gigas* × *E. ciliare*).—*E. Lillianæ* (*C. Gaskelliana* × *E. costaricensis*).—*E. madeburgensis*.—*E. Nébo* (*C. Clæsiana* × *E. O'Brienianum*).—*E. nemorale-gigas* (*C. Warszewiczii* × *E. nemorale*).—*E. O'Brieniæ* (*C. Bowringiana* × *E. O'Brienianum*).—*E. Orpetii* (*C. amethystoglossa* × *E. O'Brienianum*).—*E. salmonicolor* (*C. Mendelii* × *E. aurantiacum*).—*E. Sédenii* (*C. Bowringiana* × *E. radiatum*).—*E. Wolteriana* (*C. Schröderæ* × *E. aurantiacum*).

GEORGE V. NASH.

**EPIDÉNDRUM** (upon trees, alluding to their epiphytal habit). *Orchidaceæ*. Epiphytic orchids, some requiring hothouse and some coolhouse conditions; although a large genus, of minor importance horticulturally.

Inflorescence simple or branched, nearly always terminal; claw of the labellum more or less adnate to footless column, the blade spreading and usually deeply lobed; pollinia 4, 2 in each anther-cell, separated.—Nearly 500 species discovered and described from the New World tropics, chiefly from Cent. Amer.

*Cultivation of epidendrums.*

Epidendrums are noted as the rankest weeds amongst the orchid tribes. The remarkable success in the rais-

ing of hybrids, be it in the genus itself or with the related *Cattleya* and *Lælia*, has opened a wide field for the breeder. *Epidendrum* seedlings grow freely; the time required to bring them to the flowering stage is little compared with other orchids, and it is but a question of a short time till the blood of the epidendrums will be infused into the weaker but more gorgeous flowers of genera more difficult to grow. It is also the long stem and the grace of the racemes of the epidendra, as well as the odor of some of their species, which the hybridist will try to blend with the largeness of short-stemmed flowers, of cattleyas for example. Therefore a list of the species but rarely found under cultivation is given below, the value of which, however, will call for and justify large importations of their kind before long.

It is scarcely possible to apply any one rule for the cultivation of this widely divergent and large genus, which includes many hundreds of variable individuals geographically distributed all over tropical America. For convenience they are treated under their several separate sections.

*Section I. BARKERIA* embraces several deciduous small-growing species which generally deteriorate sooner or later under cultivation. They succeed best in small baskets, suspended from the roof, in rough loose material, such as coarse peat fiber, with a small quantity of live chopped sphagnum moss added to retain moisture, this compost freely interspersed with pieces of charcoal or broken crocks or potsherds. They are all subjects for the coolhouse, require a free moist atmosphere, shade from the sun while growing, and must be syringed frequently overhead in

1397. *Epidendrum radicans*.  
( $\times \frac{1}{6}$ )

bright weather. After the plants have matured growth, they should be removed to a rather sunny location and be syringed overhead often enough to keep them in sound condition until they start new action. While resting during winter the temperature may range from 50° to 55° F. at night, and a few degrees higher during the day. They are increased by division. This should take place as the plants start growth action in early spring, allowing at least three pseudobulbs to each piece.

*Section II. ENCYCLIUM*, of which *E. atropurpureum*, *E. nemorale* and *E. prismatocarpum* are good examples, may be grown either in pots or baskets in equal parts clean peat fiber and live chopped sphagnum, with a liberal amount of drainage, and excepting *E. vitellinum*, which must be grown cool, they require a moist sunny location with a winter temperature of 58° to 65° F. by night and several degrees advance during the day. In February and March, many species will start root or growth action; such as need it should then be repotted or top-dressed, as occasion requires. The temperature should be increased several degrees, and a greater amount of water be allowed with frequent overhead syringing on bright days. Ventilation should be given whenever the weather will permit, to keep the young growths from damping-off and the atmosphere active; at this time the plants will need light shading to pre-

vent sun-burning. The stock is increased by cutting nearly through the rhizome three or four bulbs behind the lead, when starting action; this will generally cause the latent eyes to grow, but the pieces should not be removed until the new growth is well advanced.

**Section III. AULIZEUM** includes such species as *E. ciliare*, *E. cochleatum*, and the like, the several requirements being identical with the preceding.

**Section IV. EUEPIDENDRUM.** These are mostly tall-growing species, some reed-like as in *E. evectum*, and others rambling in an irregular way, producing aerial roots along the stems as they grow; a good example of this is seen in *E. radicans*. All are best grown in pots and placed near a partition or end of a greenhouse where support may be given as the growth advances. There is, in fact, no better example of an epiphyte than *E. radicans*, the roots often attaining several feet in length, and appearing from nearly every node. A structure in which 50° F. is maintained in winter will be ample, and full exposure to sun should be permitted at all times. This prevents immature growth, and flowers are produced very freely. After flowering time, young shoots appear, often from the old stems, and when a few roots are formed and before they become too long to go into a small pot without injury, remove them and pot with care, place the young plants in a shady place for a few weeks; in this way propagation is easily accomplished. This section of epidendrums produce seeds the largest known among orchids. They are green in color, and under favorable conditions germinate very readily. It is, in fact, much easier to get the seeds to grow than to get the species to produce good seeds, for when flowering plants are produced from seed, there is an infinite variation that has not yet been understood.

**Section V. PSILANTHEMUM** contains but one species, *E. Stamfordianum*, which requires the same general treatment as those in Section II.

ROBERT M. GREY.  
E. O. ORPET.

#### A. Infl. radical. (*Psilanthemum*.)

1. *Stamfordianum*, Batem. Sts. fusiform, 12 in. long; lvs. 7-9 in.: large panicles of yellow and green fls., crimson-spotted, fragrant. Mex. to Colombia. B.M. 4759. G.C. III. 17:655. J.F. 3:251.

#### AA. Infl. terminal.

B. Sts. without bulbs: lvs. distichous, alternate; only top of column free from lip. (*Euepidendrum*.)

#### c. Fls. red, orange or vermilion.

2. *Catillus*, Reichb. f. (*E. imperator*, Hort.). Fls. cinnabar-red. Colombia. I.H. 21:162.

3. *cinnabarinum*, Salzm. Sts. 3-4 ft.: fls. orange-red, 2 in. diam., lobes of lip deeply fringed. Brazil. B.R. 28:25.—A beautiful species.

4. *radicans*, Pav. (*E. rhizophorum*, Batem.). Fig. 1397. Sts. semi-scandent, up to 5 ft. long, long white roots from opposite the lvs.: fls. up to 2 in. diam., numerous; most brilliant of the red-flowering species. Guatemala, amongst heavy grass. Gn. 24:390. O.R. 5:273.

#### cc. Fls. white.

5. *Endresii*, Reichb. f. Sts. 6-9 in.: racemes 9-12-fld.; fls. 1 in. diam., pure white; lip and column spotted purple. Costa Rica. G.C. II. 23:504. B.M. 7855. O.R. 12:145.

#### ccc. Fls., at least sepals and petals, rose or purple.

6. *ellipticum*, Graham (*E. crassifolium*, Hook.). Fls. on long scapes, clustered, rose or purple, ½ in. diam. Brazil. B.M. 3543.

7. *paniculatum*, Ruiz & Pav. Sts. 3-4 ft.: fls. ¾ in. across, lilac-purple, lip whitish yellow. Venezuela to Peru, high altitudes. B.M. 5731. I.H. 22:211.—Most free-flowering and best of paniculate species.

8. *evectum*, Hook. Sts. 3-5 ft.: peduncles nodding, 2 ft.; fls. rich purple, lip deeply fringed. Colombia. B.M. 5902.—Easily cult. and on account of its free-flowering habit deserves a place in the warm greenhouse.

#### cccc. Fls., at least sepals and petals, yellowish green.

9. *leucochilum*, Klotzsch (*E. imperator*, Hort.). Sts. 2 ft.: fls. 5-9, on long pedicels, greenish yellow; lip pure white. Colombia, 6,000-9,000 ft.

10. *eburneum*, Reichb. f. Sts. terete, 2-3 ft.: fls. 3-4 in. diam., yellowish green; lip ivory-white, with yellow calli; raceme terminal, 4-6-fld. Panama, in swamps. B.M. 5643.

139E. *Epidendrum*  
*ciliare* (×½)

BB. Sts. thickened into  
pseudobulbs.

C. Pseudobulbs 2-4-lvd.:  
labellum adnate less  
than half; column broad-  
winged. (*Barkeria*).

D. Lip obovate, obtuse.

11. *élegans*, Reichb. f. (*Barkèria elegans*, Knowl. & West.). Sts. terete, 12 in.: pedicels 24 in.; fls. 5-7, nodding, 1½ in. diam., lilac-purple; lip whitish, with purple blotch. Pacific coast of Mex. B.M. 4784.

#### DD. Lip acute.

#### E. Fls. about 1 in. across.

12. *Skinneri*, Batem. (*Barkèria Skinneri*, Paxt.). Lvs. ovate-oblong, sheathing the slender st.: peduncle terminal, bearing rose-lilac fls. about 1 in. across; petals and sepals nearly equal, petals so twisted at the base as to present dorsal surface to the observer; labellum ovate, with 3 raised lines. Guatemala. B.R. 1881. P.M. 15:1 (var. *major*).

#### EE. Fls. 2-4 in. across.

13. *Lindleyanum*, Reichb. f. (*Barkèria Lindleyana*, Batem.). Sts. slender; fls. numerous, about 2 in. across, rose-purple; labellum with a white disk; petals broader than the sepals. Cent. Amer. 1839. J.H. III. 44:53.

14. *spectabile*, Reichb. f. (*Barkèria spectabilis*, Batem.). FLOR DE ISABAL. Sts. tufted, cylindrical, 4-5 in. high; lvs. 2: raceme about 6-fld.; fls. 3-4 in. across, bright lilac; sepals linear-lanceolate; petals ovate-lanceolate; labellum white at base, red-spotted. Guatemala.

cc. *Pseudobulbs* 1-2-, rarely 3-lvd.: *labellum* adnate at base, or not up to the middle; *column* not winged. (*Encyclium*.)

D. *Fls. cinnabar.*

15. *vitellinum*, Lindl. *Pseudobulbs* ovoid, 2 in. long: lvs. 6-9 in.: peduncles 15-18 in., 10-15-fld.; fls. cinnabar-red; lip and column orange. Mex., 6,000-9,000 ft. B.M. 4107. G.C. III. 10:141.

Var. *majus*, Veitch. *Pseudobulbs* shorter: racemes denser; fls. larger and more brilliant. G.C. III. 12:159. —Very superior to the species; type no longer imported.

DD. *Fls. rose.*

16. *nemorale*, Lindl. *Pseudobulbs* subglobose, 3-4 in. high: lvs. 9-12 in.: peduncles 2 ft. long, covered with warts; fls. 3-4 in. diam., rose-colored; lip rosy mauve, streaked with purple. Mex. B.M. 4606 (as *E. verrucosum*). G.C. II. 24:332. A.F. 6:633.

DDD. *Fls. other than above.*

E. *Sepals and petals white.*

17. *dichromum*, Lindl. *Fls.* white, lip rose-colored, yellow and downy at base. Brazil.

EE. *Sepals and petals green.*

18. *osmáanthum*, Rodr. (*E. Godseffianum*, Rolfe. *E. Capartianum*, Lindl.). *Fls.* 1½ in. across, in large panicles, light green, suffused with brown; lip white, lined with rose-purple, fragrant. Brazil. B.M. 7792. —One of the handsomest species.

19. *prismatocarpum*, Reichb. f. (*E. maculatum*, Hort.). *Pseudobulbs* ovoid, tapering, 4-5 in.: lvs. 12-15 in.: fls. 1½ in. across, pale yellow-green, with purplish black spots; lip pale purple, with yellow tip and white border. Cent. Amer., 5,000 ft. B.M. 5336. G.W. 5, p. 126. O.R. 12:57.

EEE. *Sepals and petals purple or brown.*

20. *atropurpureum*, Willd. (*E. macrochilum*, Hook.). *Pseudobulbs* ovoid, 3-4 in. high: lvs. lanceolate, 12-15 in. long, dull purple-colored; peduncle 6-10-fld.; fls. 2½ in. diam., purplish brown upon greenish ground; lip yellowish white, with crimson stripes. Mex. to Venezuela. B.M. 3534. A. F. 6:609. J.H. III. 51:243, 401.

Var. *Randiánum*, Lind. & Rod. *Sepals and petals* margined with light yellowish green, the white middle lobe of lip with a red-purple-rayed blotch.

Var. *roseum*, Reichb. f. *Sepals and petals* purplish, lip bright rosy. Guatemala. P.M. 11:243.

21. *Brassávolæ*, Reichb. f. *Pseudobulbs* pear-shaped: lvs. 6-9 in.: racemes 18-24 in., 6-9-fld.; fls. 4 in. across; sepals and petals narrow, yellowish brown; lip trowel-shaped, purple, white and green. Mex. to Guatemala, 8,000 ft. B.M. 5664.

ccc. *Pseudobulbs* 1-2-, rarely 3-lvd.: *lip* adnate up to apex of *column*. (*Aulizeum*.)

D. *Lip fringed.*

22. *ciliare*, Linn. Fig. 1398. *Pseudobulbs* clavate, 4-6 in.: lvs. 4-6 in., springing from sheathing bract: peduncles 5-7-fld.; fls. yellowish green; lip white. Trop. Amer., between 5th and 20th parallel of north latitude. B.R. 784. —Plant resembles a cattleya. Intro. to cult. in 1790.

DD. *Lip not fringed.*

E. *Fls. vermilion.*

23. *aurantiacum*, Batem. Once classed in the separate group of *Epicladium*, now often accepted as a species of *Cattleya*, where it was first referred by Don. The plant grows with, and much resembles *Cattleya Skinneri*. *Fls.* 1½ in. across, orange-red, appearing in Feb. and March and lasting several weeks. Guatemala. Gt. 5:130.

EE. *Fls. not vermilion.*

F. *The lip deeply 3-lobed, the middle lobe long and lanceolate.*

24. *falcatum*, Lindl. (*E. Parkinsonianum*, Hook.). *Pseudobulbs* thin, rising from running rhizomes, monophyllous: lvs. 6-12 in., fleshy, channeled on one side: peduncles 2-5, sheathed, 1-fld.; fls. 5 in. across, greenish yellow; lip white, greenish at apex. Mex. to Guatemala. B.M. 3778. G.C. III. 44:378. —Plants grow inverted.

FF. *The lip not as in F.*

25. *venosum*, Lindl. BUTTERFLY ORCHID. Scape 1 ft., with white sheaths: lvs. 3, 4-6 in. long, linear-lanceolate: scape tumid at base, 5-7-fld.; fls. pink, chocolate and green, about 1 in. long, lasting a long time. On oaks, etc., Mex. —Of easy cult. The Fla. representative of this species is *E. tampense*, Lindl. See 9th Rept. Mo. Bot. Gard. 137, pls. 38, 39.

26. *fragrans*, Swartz. *Pseudobulbs* fusiform, monophyllous, 3-4 in.: lvs. 8-12 in.: fls. inverted, 2 in. diam., very fragrant, pale greenish or whitish; lip crimson-streaked. Guatemala, through the W. Indies to N. Brazil. B.M. 1669.

27. *cochleatum*, Linn. *Pseudobulbs* 3-4 in.: lvs. 6 in.: racemes 4-7-fld.; fls. 3-4 in. across, greenish white; lip deep purple beneath, light green above, with maroon blotch on each side, column white. Trop. Amer. from Fla. to Colombia. B.M. 572. —Intro. 1787; first epiphytical orchid to flower in England.

Garden hybrids: *E. Berkeleyi* (*E. Stamfordianum* × *E. O'Brienianum*). —*E. Burtonii* (*E. O'Brienianum* × *E. ibaguense*). —*E. Clarissia superbum* (*E. elegantulum* × *E. Wallisii*). —*E. dellense* (*E. xanthinum* × *E. radicans*). —*E. elegantulum* (*E. Wallisii* × *E. Endresio-Wallisii*). G.C. III. 19:361. —*E. Endresio-Wallisii*. —*E. keuense* (*E. evectum* × *E. xanthinum*). —*E. O'Brienianum* (*E. evectum* × *E. radicans*). G.C. III. 3:771. —*E. Phæbus* (*E. O'Brienianum* × *E. vitellinum*). —*E. radicans* (*E. Stamfordianum* × *E. radico-vitellinum*). —*E. Wallisio-ciliare*. —*E. xantho-radicans*.

*Eupidendrum*: *E. arachnoglossum*, André. Sts. 4-5 ft.: fls. rich purple-lilac; lip fringed, with orange calli. Colombia. R.H. 1882:554. —*E. Clavianum*, Cogn. Sts. up to 2 ft. tall: racemes numerous, pendulous; fls. pure white. Colombia. G.C. III. 29:70. —*E. cnemidophorum*, Lindl. Sts. 4-6 ft.: racemes ample, drooping; fls. purple, brown and yellow, fragrant. Guatemala, 7,000 ft. B.M. 5656. —*E. conopseum*, R. Br. Scape few to many-fld.: lvs. 1-3, thick; fls. green, tinged with purple, the sepals spatulate and revolute, the petals narrower and obtuse. S. Fla. and S. Once offered by Reasoner. —*E. Cooperianum*, Batem. Sts. 2-3 ft.: fls. yellow-green; lip bright purple. Brazil. B.M. 5654. —*E. costatum*, Rich. & Gal. Raceme nodding; fls. about 1 in. across, the sepals and petals reddish brown, the lip whitish, purple-marked. Mex. G.C. III. 44:425. —*E. decipiens*, Lindl. *Fls.* orange or vermilion. Colombia. —*E. Ellisii*, Rolfe. *Fls.* carmine-rose, very handsome. Colombia. —*E. fulgens*, Brongn. *Fls.* orange-scarlet, in crowded racemes. Guiana to Brazil. —*E. gracilis*, Lindl., was once offered by John Saul. —*E. ibaguense*, HBK. Sts. 2-3 ft.: fls. orange-scarlet; lip yellow. Colombia to Peru, 4,500 ft. —*E. Lambeauianum*, De Wild. Sepals and petals whitish, the lip claret. G.C. III. 44:228. —*E. myrianthum*, Lindl. Sts. 3-5 ft.: enormous panicles of rich purple fls.; lip with 2 yellow calli. Guatemala. B.M. 5556. —*E. nocturnum*, Linn. Sts. 2-3 ft.: peduncles 8-10-fld.; fls. white and yellowish, 5 in. across, very fragrant. S. Fla. and Mex. to Peru and W. Indies. B.M. 3298. Once offered by Reasoner. —*E. palpitgerum*, Reichb. f. *Fls.* beautiful lilac. Mex. —*E. Pfavii*, Rolfe. Sts. 4-6 ft. high: fls. light purple; lip with white disk, in numerous racemes. Costa Rica. —*E. Pseudopidendrum*, Reichb. f. Sts. 2-3 ft.: fls. 3 in. diam., green; lip orange-red and yellow. Cent. Amer., 4,000 ft. B.M. 5929. —*E. raniferum*, Lindl. Sts. 2-3 ft.: fls. yellow-green, thickly spotted with purple. Mex. to Guiana. B.R. 28:42. —*E. rigidum*, Jacq., was once catalogued by Reasoner. —*E. Schomburgkii*, Lindl. Sts. 2-3 ft.: fls. vermilion. Guiana, Brazil, Quito. B.R. 24:53. —*E. stenopetalum*, Hook. Sts. up to 2 ft.: fls. 1½ in. across, rosy mauve, the lip with a white blotch. Jamaica. B.M. 3410. —*E. syringothyrsis*, Reichb. f. Sts. 4-5 ft.: fls. deep purple; lip and column with orange and yellow, crowded in long racemes. Bolivia, 8,000-9,000 ft. B.M. 6145. —*E. Wallisii*, Reichb. f. Sts. 4-6 ft.: fls. yellow, some purple spots; lip orange and purple, upon white ground. Colombia. 4,000-7,000 ft. Has lateral as well as terminal racemes.

*Encyclium*: *E. advena*, Reichb. f. *Fls.* yellow, veined brown; lip yellowish white, purple-streaked. Brazil. —*E. alatum*, Batem. *Fls.* 2 in. across, purple and green; lip yellowish, streaked with purple, fragrant. Cent. Amer. B.M. 3898. —*E. bifidum*, Aubl. *Fls.* pale green, dotted with purple; lip rose, orange and white. W. Indies, Guiana. B.R. 1879. —*E. Friderici-Guilielmi*, Warsc. & Reichb. f. *Bulbs* 4-5 ft.: fls. dark purple; base of lip white and yellow. Peru, 6,000-8,000 ft. I.H. 18:48. —*E. gallopavinum*, Reichb. f. *Fls.* brown in large racemes; lip yellow. Brazil. —*E. oncidoides*, Lindl. Panicles up to 6 ft. long; fls. yellow and brown, sweet-

scented. Stately species. Guiana. B.R. 1623.—*E. phaniceum*, Lindl. Panicles 2-3 ft.; fls. deep purple, mottled green; lip rich violet, stained crimson. Handsome. Cuba.—*F. virgatum*, Lindl. Scape up to 7 ft. high; fls. small, up to 20, greenish, stained brown. Mex.

Aulizeum: *E. variegatum*, Hook. Racemes many-fl'd.; fls. fragrant; sepals and petals pale yellow, the lip rose or white-and-rose-spotted. S. Amer. B.M. 3151.

Other species mentioned in horticultural literature are: *E. campylostylus*, Reichb. f. A curious species with glaucous green pseudobulbs and lvs.; fls. yellowish tinged with chocolate color. Cent. Amer.—*E. Lambda*, Lind. Closely allied to *E. fragrans*. Sepals and petals light salmon-color; lip cream-yellow with violet lines; crest velvety. Colombia.—*E. laterale*, Hort. Infl. produced on a rudimentary pseudobulb as in *E. Stamfordianum*. Cent. Amer.—*E. pterocarpum*, Lindl. Of diminutive growth, chiefly of botanical interest. Mex.—*E. punctiferum*, Reichb. f. Fls. in erect spikes, green, the lip spotted with purple. Brazil.—*E. purpurachylum*, Rodr. "Sepals and petals dull olive-green, tinged with brown; corrugated front lobe of lip deep purple, with whitish yellow margin; fls. fragrant, not unlike violets."—*E. saccharatum*, Kränzl. Raceme 15-20-fl'd.; fls. green, marked with dark brown; lip white, rose-purple at apex. Guiana.—*E. Stallforthianum*, Kränzl. Sepals and petals dull brown; column ivory-white; fls. have a peculiar and disagreeable odor. Mex. G.C. III. 51:114.—*E. tripunctatum*, Lindl. Intro. in 1881 and now reappearing in cult.

GEORGE HANSEN.

GEORGE V. NASH.†

**EPIDIACRIUM** (compounded of Epidendrum and Diacrium). *Orchidaceæ*. A genus established to contain hybrids between Epidendrum and Diacrium.

The following is sometimes found in collections: *E. Cölmarii* (*E. ciliare* × *D. bicornutum*).

**EPIGÆA** (Greek, *epi*, upon, *gaia*, earth; in reference to the trailing growth). *Ericaceæ*. Evergreen spring-blooming plants, herbaceous in appearance but with woody creeping stems, sometimes planted.

Leaves alternate, petiolate, entire, leathery: fls. usually dioecious, sometimes perfect, in short terminal or pseudo-axillary spikes, each in the axil of a green bract and with 2 green bractlets; sepals 5, green; corolla pink or white, salver-shaped, with 5 lobes; stamens 10, attached to the base of the corolla-tube, the 2-celled anthers dehiscing by slits not, as is usual in the *Ericaceæ*, by pores; style columnar; stigma 5-lobed; ovary densely hairy, 5-celled, with many ovules; fr. depressed-globose, fleshy, dehiscent along the partitions, the many minute seeds set on the surface of the white succulent placentæ.—Two species, N. E. Amer. and Japan.

*repens*, Linn. **TRAILING ARBUTUS. MAYFLOWER.** Fig. 1399. Spreading on the ground in patches sometimes 2 ft. diam., the hirsute sts. rooting; lf.-blades ovate-oblong to orbicular, cordate or rounded at the base, obtuse or broadly acute at the apex, sparingly hirsute on the margins and both surfaces, 1-3 in. long; fls. fragrant, the corolla-lobes spreading, those of the male fls. much larger than the female; stamens in the female fls. often reduced to mere rudiments of filaments; stigmas spreading in the female fls., folded together in the male; fr. berry-like after dehiscence, the axis, dissepiments, and placentæ fleshy. Newfoundland to Sask., south to Fla., Ky., and Wis.—It grows only in acid soils.

Trailing arbutus, probably the best beloved of all the early wild flowers of the eastern United States, is rarely seen in cultivation. Yet it thrives in the same acid peaty sandy well aerated soils as the blueberry, and like the blueberry it has in and on its roots a mycorrhizal fungus upon which it probably depends for nutrition. One of the most satisfactory potting mixtures is nine parts finely sifted kalmia peat, one part clean sand, and three parts clean broken crocks. In watering the plants one should use rain-water, bog-water, or some other water free from lime.

Wild plants may be transplanted, preferably in autumn or very early spring, care being taken to lift a large portion of the root-mat without disturbing the roots. Such plants should be kept in a coldframe or coolhouse and until abundant new roots are formed should receive little or no direct sunlight. They may be propagated by division or by layers, but the resulting plants are seldom symmetrical.

The best method of propagating trailing arbutus is by the seed. The fruit, which is often borne in abundance on vigorous female plants, ripens at the same season as the wild strawberry. At maturity and while still herbaceous the wall of the fruit splits from the center into five valves which turn backward in a green rosette exposing the white fleshy edible berry-like interior,  $\frac{1}{4}$  to  $\frac{1}{3}$  of an inch in diameter and dotted with seeds. The fruits disappear quickly after dehiscence, commonly within a few hours, being eagerly sought by ants, snails, and birds. A fruit bears usually 300 to 500 seeds. The seeds, which are easily separated from the pulp by rubbing between the fingers, should be sown at once in a well-drained shallow box, in a mixture of two parts finely sifted kalmia peat and one part of clean sand, covered about  $\frac{1}{8}$  of an inch with the same material, and watered slowly but thoroughly with a very fine rose. If covered with a glass and kept away from direct sunlight a second watering may not be required before germination. The seeds come up in three to four weeks, and in their earliest stages after germination often require protection from ants. This is best accomplished by setting the seed-boxes on pots inverted in saucers of water. In the heat of summer young seedlings, and older plants as well, can not stand full sunlight. A lath shade with spaces of the same width as the lath usually furnishes sufficient protection. In the third or fourth month from germination, when the plants are about  $\frac{3}{8}$  of an inch in diameter, they should be potted in 2-inch pots in the mixture of peat, sand, and crocks already described, and the pots plunged in sand in shallow boxes.

If carried through the first winter in a greenhouse, with a night temperature of 55° to 60° and a day temperature of about 65° to 70°, the plants continue their growth all winter, and in the following summer some of them even without transfer to larger pots will lay down a few clusters of flower-buds, in preparation for the next spring's blooming, when they are a year and a half old. Many of the plants, however, do not flower until they are two and a half years old, their

1399. Trailing arbutus or Mayflower —*Epigaea repens*.

XXXVIII. The California poppy.—*Eschscholtzia californica*.

rosettes having reached a diameter of about 7 to 10 inches.

The flower-buds are formed from midsummer to autumn. If the plants are kept in a warm greenhouse during the winter the flower-buds seldom open. To make them open normally the plants must be subjected to a prolonged period of chilling. Actual freezing is not necessary. The best chilling temperature for the greenhouse is a little above freezing, about 35°. Alternate freezing and thawing, with strong sunlight, is likely to injure the foliage. Strong sunlight without freezing heightens the color of the flowers. After two to three months of chilling the plants may be forced, if early flowers are desired, by alternating the same low night temperature with a day temperature of 45° to 60°. Plants kept in a cool humid atmosphere often remain in flower three to four weeks, redolent with their well-known delightful fragrance. The male flowers, with their yellow centers, are much larger and prevailing much pinker than the green-centered female flowers. In cultivated plants the corollas sometimes have a spread of  $\frac{1}{8}$  of an inch. The most robust plants have been secured by plunging the pot in moist sphagnum in a pot of 2 inches greater diameter. The roots then grow through the hole in the bottom of the inner pot and develop profusely in the moist, well aerated sphagnum of the outer pot. Old plants which have become ragged at the center may be revived by cutting the stems back almost to the main root immediately after flowering. They then throw out a new circle of branches with new and bright foliage and flower profusely the following spring.

FREDERICK V. COVILLE.

**EPILÆLIA** (compounded of *Epidendrum* and *Lælia*). *Orchidaceæ*. A genus established to include hybrids of these genera.

*E. belairensis* (*E. ciliare* × *L. autumnalis*).—*E. Charlesworthii* (*E. radicans* × *L. cinnabarina*).—*E. Fletcheriana* (*E. atropurpureum* × *L. harpophylla*).—*E. Hardyana* (*E. ciliare* × *L. anceps*). C. O. 1.—*E. heateriensis* (*E. O'Brienianum* × *L. cinnabarina*).—*E. Lawrencei* (*E. vitellinum* × *L. tenebrosa*).—*E. Lionetii* (*E. atropurpureum* × *L. purpurata*).—*E. Margaritæ* (*E. Parkinsonianum* × *L. grandis*).—*E. Sylvia* (*L. cinnabarina* × *E. Cooperianum*).—*E. Veitchii* (*E. radicans* × *L. purpurata*).—*E. vitellbrosa* (*E. vitellinum* × *L. tenebrosa*).

GEORGE V. NASH.

**EPILØBIUM** (Greek, *upon the pod*, referring to the structure of the flower). Including *Chamænerion*. *Onagraceæ*. Border plants, with willow-like foliage, and large showy spikes of deep pink, rosy crimson or white or even yellow flowers borne from June to August.

Herbs or sub-shrubs, sometimes annual, erect, sprawling or creeping: lvs. alternate or opposite, toothed or entire: fls. axillary or terminal, solitary or in spikes or racemes, rosy purple or flesh-colored, very rarely yellow; calyx-tube little, if at all, produced beyond the ovary; petals 4, obovate or obcordate, erect or spreading; stamens 8; ovary 4-celled; seeds comose; stigma often 4-lobed: caps. long and narrow, 4-sided and 4-valved.—Species about 200 or more, in many parts of the world, mostly in temperate regions.

The taller species, like *E. angustifolium* and *E. hirsutum*, make very rank growth in moist places, and are therefore especially adapted for the wild garden or for naturalizing along the water's edge and in low meadows. The underground runners reach far, and the plants spread fast when not kept in bounds. Propagation is by division or seeds.

*angustifolium*, Linn. (*E. spicatum*, Lam. *Chamænerion angustifolium*, Scop.). GREAT WILLOW-HERB. FIRE-WEED. In cult. mostly branched and 3-5 ft. high; in the wild simple or branched, 2-8 ft. high: lvs. alternate, very short-petioled, lanceolate, entire or

minutely toothed, 2-6 in. long, 4-12 lines wide, pale beneath, acute, narrowed at bases: fls. spreading, in long, terminal spike-like racemes, petals rounded at tip; stigma 4-lobed: caps. 2-3 in. long. Eu., Asia, N. Amer. B.B. 2:481. Var. *álba*, Hort., has pure white fls. suitable for cutting; also occurs wild. This variety was perfected in England. It forms a compact bush.

*hirsutum*, Linn. Stout, 2-4 ft. high, with short but conspicuous soft straight hairs: lvs. oblong-lanceolate, usually opposite, sessile and often clasping, with many small, sharp teeth, 1-3 in. long, pubescent on both sides: fls. erect, axillary, about 1 in. across; petals notched: weed from Eu., showy, and sometimes found in old gardens.

*Dodonæi*, Vill. (*E. rosmarinifolium*, Haenke). Perennial, 1-3 ft., blooming in midsummer, mostly erect: lvs. linear, tapering somewhat toward either end, entire, smooth or somewhat soft-hairy: fls. red, the infl. terminal on the branches. Eu.

*obcordatum*, Gray. Glabrous perennial: decumbent, sts. 3-5 in. long, 1-5-flid.: lvs. numerous, opposite, ovate, sessile,  $\frac{3}{4}$  in. or less long: fls. bright rose-color, the petals  $\frac{1}{2}$  in. long and obcordate; stamens yellow, shorter than declining style: caps. short and thick. Calif. in the high Sierras, and in Nev.—Offered as an alpine. A handsome species.

*luteum*, Pursh. Nearly simple, 1-2 ft., nearly glabrous: lvs. ovate or elliptical to broad-lanceolate, toothed, slightly fleshy, 1-3 in. long, sessile or with a short-winged petiole: fls. bright yellow, the petals  $\frac{3}{4}$  in. long; style often exserted: caps. long-stalked, somewhat puberulent. Ore. to Alaska.

*E. abyssinicum album* is offered abroad, as "pure white, pretty" the name does not appear to have botanical standing.—*E. latifolium*, Linn. (*Chamænerion latifolium*, Sweet). Erect, caespitose, about 1  $\frac{1}{2}$  ft.: lvs. lanceolate or ovate-lanceolate, tapering at both ends, thick: fls. purple, showy, sometimes 2 in. across. Newfoundland to Ore. and north.

L. H. B.

**EPIMEDIUM** (Greek, *like Medion*, a plant said to grow in Media; a name from Dioscorides, retained by Linnaeus). *Berberidaceæ*. Herbs suitable for rock-gardens and shady places.

This genus contains some of the daintiest and most interesting plants that can be grown in the hardy border, and *E. macranthum*, particularly, is as distinct, complicated and fascinating as many of the rare, tender and costly orchids. The whole family to which it belongs is exceptionally interesting, and is one of the most striking of those rare cases in which the cultural, botanical and artistic points of view have much in common. Of the 8 or 9 genera of this family only *Berberis* and *Nandina* are shrubs, all the others being herbs, with creeping, underground sts., and all small, choice, curious, and cult. to a slight extent, except *Bongardia* and *Leontice*. *Podophyllum* contains our mandrake; *Caulophyllum* the quaint blue cohosh; and the others are *Aceranthus*, *Achlys*, *Diphylleia*, *Jeffersonia* and *Vancouveria*. A collection of all these plants should make a charming study. What appear to be petals in *E. macranthum* are really the inner row of sepals, colored like petals, and performing their functions, while the long spurs or nectaries are supposed to be highly specialized petals. *Epimedium* has 8 sepals and 4 petals, which are mostly small and in the form of nectaries: stamens 4: caps. opening by a valve on the back: lvs. pinnately twice or thrice dissected. They grow a foot or two high. For *E. diphyllum*, see *Aceranthus*, which is distinguished by its flat, not nectary-like petals, and its lvs. with a pair of lfts. on each of the 2 forks of the petiole.—There are 11 species, all natives of the northern hemisphere, but some are found as far south as N. Afr. There is none native in Amer. The Garden, 48, p. 486, shows what a charming picture can be made of the foliage alone when cut and placed in a bowl. The plants retain their foliage all winter, especially in sheltered spots under trees.

Epimediums thrive best in partial shade, and are particularly well suited for rockeries and the margins of shrubberies. Almost any soil will answer for them. The peculiar bronzy tints of the young foliage con-

tion, its spurs having an individuality difficult to describe. Var. *rùbrum*, Hort., is presumably an error, as a red-fl. form would be very unexpected.

AAA. *Spurs much shorter than the inner sepals, being, in fact, merely small nectar-glands.*

B. *Lvs. once or twice ternate.*

*pinnatum*, Fisch. Fig. 1400. Lvs. usually biternate, with 5 lfs., 3 above and 1 on each side; lfts. with a deeper and narrower basal cut than in *E. macranthum*, the whole plant densely hairy; scape about as long as the fully developed lvs.; fls. typically bright yellow; nectaries red, a third or a fourth as long as the inner sepals. Shady mountain woods of Persia and Caucasus. B.M. 4456. Gn. 46:356, (erroneously as *E. macranthum*); 48, p. 486. G. 18:706.—Best suited to the alpine garden.

Var. *élegans*, Hort., presumably has larger, brighter and more numerous fls. *E. sulphureum* of European catalogues is regarded by J. W. Manning and J. B. Keller as a pale yellow-fl. form of *E. pinnatum*, but by Voss as a variety of *E. macranthum*. A yellow form of the violet-fl. *E. macranthum* would be very surprising.

Var. *colchicum*, Hort. (*E. colchicum*, Hort.), has brilliant golden yellow fls. and nectaries 1-1½ lines long.

BB. *Lvs. always once ternate.*

*Perralderianum*, Coss. This is the African representative of *E. pinnatum*, from which it differs in the key characters and also in the much more strongly ciliate-toothed lfts.; when young the lfts. have rich bronze markings, making a handsome showing. Its fls. are a "paler yellow than the typical *E. pinnatum*. It is far from improbable that specimens connecting them will be found in S. Eu., if not in Afr." Algeria. B.M. 6509.—Lvs. remain all winter. Less desirable than *E. pinnatum*.

*E. diphyllum*, Lodd. See *Aceranthus diphyllus*.—*E. niveum* is catalogued by Van Tubergen as a synonym of *E. Musschianum*, but the chances are that all the plants advertised as *E. niveum* are *E. macranthum* var. *niveum*. The spurs are so obviously longer in *E. macranthum* that there is no reason for confusion.

WILHELM MILLER.

N. TAYLOR.†

**EPIPÁCTIS** (Greek, *epipegno*; it coagulates milk). *Orchidaceæ*. Hardy terrestrial orchids of minor value.

Leafy orchids with creeping rootstocks and unbranched sts.: lvs. ovate or lanceolate, with plaited veins; fls. purplish brown, nearly white or tinged red; lower bracts often longer than the fls.; sepals free, spreading, nearly as large as the petals; lip free, deeply concave at base, without callosities, narrowly constricted and somewhat jointed in the middle, the upper portion dilated, petaloid.—Ten or a dozen species in the north temperate zone. The first mentioned may be secured through dealers in native western and Japanese plants; the second is listed in the American edition of a Dutch catalogue. For other definitions of the name *Epipactis*, see *Goodyera*.

*Royleana*, Lindl. (*E. gigantea*, Douglas). Stout, 1-4 ft. high; lvs. from ovate below to narrowly lanceolate above, 3-8 in. long; fls. 3-10, greenish, strongly veined with purple. June, July. Wash. to Santa Barbara, east to S. Utah and W. Texas, on banks of streams. Also Himalayas. Intro. 1883. Mn. 8:145.

*atrórubens*, Schult. (*E. rubiginosa*, Crantz). Lvs. often reddish; fls. and ovary dark purple; lip oval, acute, or slightly notched; bracts equaling the fls. or rarely longer. July-Sept. Eu., W. Asia. L. H. B.

**EPIPHRONITIS** is a bigeneric orchid hybrid of *Epidendrum* and *Sophranitis*, for a picture of which see R.H. 1896:476. It has about 10 fls., chiefly a brilliant scarlet, set off with bright yellow. Gt. 46, p. 555.

1400. *Epimedium macranthum*. a, *E. alpinum* var. *rubrum*; b, *E. pinnatum*; showing three types of spur or nectary.

trast well with the variously colored flowers. Propagation by division. (J. B. Keller.)

A. *Spurs conspicuous, often 1 in. long, sometimes twice as long as the showy inner sepals.*

*macranthum*, Morr. & Decne. Fig. 1400. Lvs. thrice ternate; lfts. cordate-ovate, unequal at the base, sharply toothed; petioles with short, spreading, conspicuous hairs; outer sepals sometimes colored bright red, remaining after the larger and showier parts of the fl. have fallen; inner sepals ovate-lanceolate, violet; spurs white. Japan. B.R. 1906. P.M. 5:151. Not Gn. 46:356, which is *E. pinnatum*. Var. *niveum*, Voss (*E. niveum*, Hort.), has pure white fls. G.W. 3, p. 591. Var. *roseum*, Voss (*E. roseum*, Hort. *E. niveum* var. *roseum*, Hort.), has fls. white, tinged with pink or pale rosy red. Var. *violaceum*, Voss (*E. violaceum*, Morr. & Decne.), has violet spurs, shorter than in *E. macranthum*, but much larger than in the other species. B.M. 3751. B.R. 26:43. H.F. 4:168.—A very interesting species. The *E. lilacea* advertised in some American catalogues seems to belong here. *E. lilacea* is a name unknown in botanical literature.

AA. *Spurs medium-sized, nearly as long as the inner sepals.*

B. *Inner sepals bright red.*

*alpinum*, Linn., var. *rùbrum*, Hook. (*E. rùbrum*, Morr.). Fig. 1400. Lvs. biternate (but Hooker's picture shows tendency to thrice ternate condition), minutely toothed; spurs white, marked with red, as in Fig. 1400, which shows the very distinct appearance of the fls. Japan. B.M. 5671. R.B. 3, p. 33.—Hooker says this differs in no way from *E. alpinum*, except in the larger and red fls., while the type which grows wild in England (though probably not native) has dull reddish yellow fls., and, though advertised, is probably not in cult.

BB. *Inner sepals whitish or pale yellow.*

*Musschianum*, Morr. & Decne. Lvs. only once ternate, sharply toothed, as in *E. macranthum*: all floral parts whitish or pale yellow. Japan. B.M. 3745.—The least showy kind, but worth growing in a collec-

**Veitchii**, Hort. (*Epidendrum radicans* × *Sophranitis grandiflora*). Fls. like those of *Epidendrum radicans*, which it much resembles in habit, but the parts all broader. C.O. 1.

GEORGE V. NASH.

**EPIPHYLL**. A plant that grows on a leaf. It is a kind of epiphyte. The epiphylls are algæ, lichens, liverworts, and mosses. The name is applied to those species or kinds that find their physical support on foliage leaves rather than to those that are parasitic on them as are the fungi. Epiphyllous plants are likely to be most abundant in the tropics.

**EPIPHYLLÁNTHUS** (*flower upon the leaf*). *Cactaceæ*. Epiphytic: sts. much branched, jointed, ribbed: areoles bearing setæ instead of spines: fls. resembling those of *Zygocactus*; ovary angled.—One species known. Native of Brazil. For cult., see *Succulents*.

**obtusángulus**, Berger (*Cereus obtusángulus*, Schumann). Joints somewhat flattened, about 10-ribbed: stamens of two kinds.—Although usually considered a *Cereus*, it is more closely related to *Zygocactus*, but from both it seems generically distinct. Indeed Berger says it resembles certain *Opuntias* and seems to have a relationship with *Rhipsalis*. It is not grown in this country, and is still rare in Eu.

J. N. ROSE.

**EPIPHÝLLUM** (*on a leaf*; refers to the leaf-like branches on which the flower grows). *Cactaceæ*. Spineless upright branched flat-stemmed cacti with very large and showy flowers, some of them popular as houseplants.

Branches flat, 2-edged, crenate or serrate on the margins, spineless: fls. usually large, mostly nocturnal; petals white, red, or yellow; stamens elongated, numerous: fr. oblong in outline, bearing a few bracts, red, juicy; seeds numerous, black. In the Cyclopedia of American Horticulture, the name *Phyllocactus* was used for this genus, but this is a much later name and hence it is given up. The epiphyllums of the first Cyclopedia will be found under *Zygocactus*. For cult., see *Succulents*.

Several hundred hybrids are in the trade, the most common ones being with *E. crenatum*, *E. Ackermannii* and *E. phyllanthoides*. Fig. 1401. Crosses are often made with the various *Cereus* allies, such as *Heliocereus speciosus*, and with some species of *Echinopsis*.

A. Tube of fl. always elongated, usually much longer than the limb; petals white or yellowish: mostly night-bloomers.

B. Style white.

C. Branches thin, usually spreading in some plane: petals pure white.

**oxypétalum**, Haw. (*Phyllocactus grándis*, Lem.). Very large, sometimes 20 ft. long, with numerous short side branches, and these in the same plane with the main st., thin and lf.-like: fl. large (nearly a foot long), white, night-blooming (sometimes described as day-blooming). Originally from Mex., but said to be found in Honduras and Guatemala; also reported from Cuba, but surely not native there. G.W. 10:560 (as *Phyllocactus latifrons*).—One of the commonest and best species in cult.

CC. Branches thick, not spreading in the same plane: petals cream-colored or yellow.

D. Fls. large: sts. with shallow crenations.

**crenátum**, Don (*Phyllocactus crenátus*, Lem.). Sts. about 3 ft. long, erect, thick, strongly crenate, somewhat glaucous: midrib very thick: fl. large, 6–10 in. long, said to be a day-bloomer; petals white or cream-colored in life, drying yellow; tube 4–5 in. long; style said to be white; very fragrant. Guatemala and S. Mex., and said to come from Honduras.

DD. Fls. small for the genus: sts. with deeply cut margins.

**angùliger**, Don (*Phyllocactus angùliger*, Lem.). About 3 ft. high, much branched below: branches narrow, thick, with deeply cut margins: fls. 5–8 in. long, with a slender tube; petals yellow.

BB. Style red.

C. Sts. stiff, erect.

**strictum**, Brit. & Rose (*Phyllocactus strictus*, Lem.). Erect, branching, reaching a height of 10 ft., with long cylindrical branches and shorter, lf.-like secondary branches: crenatures or teeth rather deep, unequal on the opposite sides: bristles wanting: tube of the fl. very long and slender, outer sepals brownish, inner pure white; the fl. opens late in the evening and closes before dawn; in full bloom the sepals are very strongly recurved. Said to come from Cuba.—Often found in collections under the name of *P. latifrons*.

CC. Sts. rather weak, spreading.

D. Petals very narrow: areoles bearing black bristles.

**látifrons**, Zucc. (*Phyllocactus látifrons*, Link. *P. stenopétalus*, Salm-Dyck?). Branches very long and large, crenate or somewhat serrate, acute or acuminate: midrib and usually side ribs evident: areoles with rather large scales and dark bristles: fl. 8–10 in. long, spreading and in full bloom bent backward; petals narrow. Supposed to be from Mex., but not known from wild material.—Much advertised as the queen cactus.

DD. Petals broader: areoles without bristles.

**Hodkeri**, Haw. (*Phyllocactus Hodkeri*, Salm-Dyck). Sts. 6–10 ft. high: branches rather thin, light green, strongly crenate: fls. night-blooming, 8–9 in. long; fl. tube narrow, tinged with yellow; sepals narrow, lemon-yellow; petals pure white, narrow, 2 in. long; stamens in a single series; style red. Brazil and Guiana. B.M.

1401. One of the many hybrid Epiphyllums.

2692 (as *Cactus phyllanthus*).—Although long in cult., the species is not now well known, there being 2 or more closely related species in cult. under this name.

AA. Tube of fls. short, always shorter than the limb: day-bloomers.

B. Style reddish: fls. 4½ in. broad.

**Áckermannii**, Haw. (*Phyllocactus Áckermannii*, Salm-Dyck). Fig. 1402. Sts. numerous, sometimes reaching 3 ft., somewhat recurved: branches usually less than a foot long, with evident middle and side ribs: areoles on the lower and younger shoots bearing short bristles: fls. scarlet-red outside, carmine-red within,

the throat greenish yellow, tube very short, the limb wide-spreading, 4-6 in. diam. B.R. 1331.—Not known in the wild state.

BB. *Style white; fls. smaller than the last.*

**phyllanthoides**, Sweet (*Phyllocactus phyllanthoides*, Link). Branches at length hanging, cylindrical at base, lanceolate above; serratures obtuse; middle and side ribs evident; bristles few; fl.-tube 2 in. long or less, with spreading scales, the limb somewhat longer, often striate. S. Mex.

J. N. ROSE.

**EPIPHYTES.** Literally "air plants:" those plants that do not grow in earth or water, but are supported in air on trees or other objects and usually drawing no organic nourishment from such object or support.

True epiphytes are widely distributed in all climates, but it is in the moist tropics that they become so numerous and conspicuous as to arouse the special interest and enthusiasm of the serious student as well as of the traveler or casual observer. One thinks of epiphytes as growing upon trees, and trees are usually the supporting plants. The term merely signifies that ecological type that has the habit of growing upon other plants, although in this account it is not the purpose to discuss such seaweeds or other algae as grow upon larger plants in the water. The word epiphyte also involves a contrast with parasite, the latter denoting that nourishment and water are derived from the living tissues of the supporting plant or host. The epiphytic habit implies no particular method of nutrition, and the epiphytes are entirely independent of the nutrition of the

supporting plant. This habit is not restricted to a single class, or to a few families of plants, although in some families many representatives of the type have been developed, while in related families there may be none. The seed plants are represented by many species of tropical orchids, arums, bromeliads, and numerous others; lycopods, ferns, mosses and liverworts all contribute many examples; and in the lower groups of plants the lichens are in some regions dominantly epiphytic.

The luxuriant tropical rain-forest is regarded as the climax in development of vegetation. In describing this type, Humboldt declared that "forest is piled upon forest." Under such conditions the trunks and branches are clothed with larger epiphytes, and the leaves of some species accommodate algae and lichens. It is in the South American tropical forests that the better known of our greenhouse epiphytes are native. Orchids, bromeliads, and arums are among the most abundant. In the Javanese forests, the wealth of species is great, but mosses, ferns and lycopods are particularly numerous, and these are accompanied by some interesting species of *Ficus*, epiphytic for a time, and by the striking *Rhododendron javanicum*, among others. In the mountain forests of tropical regions there are, as epiphytes, representatives of several families of ferns, likewise many mosses and lichens. The dicotylous and certain coniferous forests of Europe and America harbor a few mosses and liverworts and numerous species of lichens. A conspicuous epiphyte of the southern states, as well as of tropical America is the long or Florida moss, *Tillandsia usneoides*, the extremest epiphyte among the Bromeliaceæ. Accompanying this, the common polypody fern is also found on trees. Going northward, the total number of epiphytic lichens may decrease, but several of the larger forms seem to become more abundant and some of the moss-like usneas extend to the northernmost latitude of tree growth.

The habit of growing upon trees renders epiphytes subject to an inconstant water-supply. On this account the larger and more delicate epiphytes are restricted to regions constantly moist. Even in the moist forest, the species less resistant to drying out are found on the lower branches, and those more resistant maintain themselves higher up, so that there is a distribution in strata, analogous to the lateral distribution of species about the edge of a pond. In general, however, there is exposure to drying out, and, as might be anticipated, these plants exhibit the structural characteristics of xerophytes (dry-land plants). Many of them are modified so that transpiration is reduced, and they are able to withstand considerable desiccation. Among greenhouse forms this is notably true of many orchids and lichens. Moreover, many species of orchids possess special tissues to which water is transported and there accumulated as a "reserve" supply. Leaf-tissues may function in this way, but usually more important are the bulb-like enlargements of the stems.

Of special interest are the organs of absorption of certain epiphytes. Aërial roots are characteristic of tropical arums and orchids. The typical air-root is provided with an outer cylinder of tissue, the velamen, derived from the epidermis, consisting at maturity of dead cells capable of taking up liquid water and substances in solution like a sponge. From these roots as capillary reservoirs, the supply is gradu-

1402. *Epiphyllum Ackermannii*. ( $\times \frac{1}{2}$ )

ally absorbed by the living tissues. Rain, dew, or moist substrata may furnish the water, but the view that these roots absorb water vapor is erroneous. The Bromeliaceæ are peculiar in the possession of certain absorbing leaf-scales or hairs. The Florida moss possesses such hairs over the entire surfaces of the thread-like stems and leaves, and the plant is rootless. There are all gradations between this and the soil-rooted pineapple-like forms. The arrangement of the leaves in many of the bromeliads possessing larger leaves is such as to establish after a rain a temporary reservoir about the leaf-bases. The absorbing scales of the bromeliads exhibit features worthy of note in three particulars: (1) When dry certain dead cells absorb water greedily; (2) with absorption they assume a position making possible the entry of water to a considerable surface of living cells, and (3) with collapse, due to loss of water, the spaces admitting water are closed and loss is minimized.

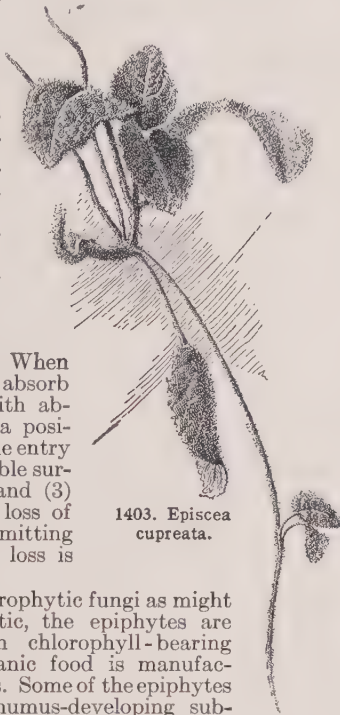

Aside from such saprophytic fungi as might be considered epiphytic, the epiphytes are amply provided with chlorophyll-bearing tissue; therefore, organic food is manufactured as in other plants. Some of the epiphytes growing upon such humus-developing substrata as the decaying bark of trees, or such as passively accumulate humus and other materials in the vicinity of their absorbing surfaces, might absorb some organic compounds as well as salts in this way; but this supply of organic matter is certainly inconsequential in most cases. Water and salts are secured either through the air-roots, as described, or partially through normal roots, when such occur. Many species, epiphytic at first, ultimately send roots into the soil, and then secure water and salts largely through the terrestrial habit.

In the forest, certain of the seed-bearing epiphytes are specialized with respect to supporting plants, often due to the special nature of the protection offered, or to the physical advantages of the substratum in regard to fixation of the plant. Most species are markedly unspecialized and may be grown in the greenhouse most successfully.

B. M. DUGGAR.

**EPIPRÉMNUM** (*upon the trunk of trees*). *Araceæ*. Resembling the genus *Rhaphidophora* but has fewer ovules, 2 or more 1-seeded berries not confluent, and albuminous kidney-shaped instead of almost terete seeds. About 8 species from Malay and Polynesia. *E. giganteum*, Schott. A robust climber over 100 ft. high, the sts. emitting long rope-like roots from every growth: lvs. cordate-oblong, 6-8 ft. long, including the petiole which is as long as the blade and winged throughout its length: spathe about 1 ft. long, ending in a curved beak-spadix as long as spathe. Malay Penins. B.M. 7952.

**EPÍSCIA** (Greek, *shady*; they grow wild in shady places). *Gesneriáceæ*. Choice and interesting warm-house plants, *E. cupreata* being much prized for baskets

1403. *Episcia cupreata*.

Herbs, with long, short or no hairs: st. from a creeping root, branched or not: lvs. opposite, equal or not in size: fls. pedicelled, axillary, solitary or clustered; corollas mostly scarlet, rarely whitish or purplish; tube straight or curved, more or less spurred at the base; limb oblique or nearly equal; lobes 5, spreading, rounded —Perhaps 30 species, all Trop. American.

*Episcia cupreata* is one of the standard basket plants, especially for the warmest greenhouses. It can also be used in pyramids and mounds, as told under *Fittonia*. As it does not require so close an atmosphere as the *fittonias*, it can be grown in some living-rooms and perhaps outdoors in summer in a shady place. Its chief charms are the slender, trailing habit, the soft hairiness of the leaves, the coppery hue, which is often laid on like paint in two broad bands skirting the midrib, and the rarer and perhaps finer metallic bluish luster of which one occasionally gets a glimpse in a finely grown specimen. Give very rich, fibrous loam, mixed with peat, leaf-mold and sand; in summer partial shade. (Robert Shore.)

A. Fls. pale lavender to white.

**chontalénsis**, Hook. (*Cyrtodeira chontalénsis*, Seem.). St. stout, more or less ascending, dark reddish purple, 6-10 in. long; lvs. opposite and irregularly whorled, 3-4 in. long, oblong-ovate to elliptic-ovate, crenate, obtuse, rounded at the base, decidedly convex on both sides of the midrib and between the much-sunk veins; margins recurved, green, marked with regular purple patches, which advance from the margins between the veins toward the midrib and are more or less oblong: fls. solitary or in small clusters; corolla-tube with a sac at the base, the limb oblique, 1½-2 in. across, with small and regular but conspicuous and beautiful teeth. Chontales region of Nicaragua. B.M. 5925. R.B. 22:241. F.S. 18:1924.

AA. Fls. scarlet.

B. Lvs. usually not green, or only partially so.

**cupreata**, Hanst. (*Achimenes cupreata*, Hook.). Fig. 1403. Sts. slender, creeping, branched, rooting at the joints, with a main branch rising erect a few inches, which bears the fls. and the largest lvs.: lvs. copper-colored above: fls. solitary, 9 lines wide, scarlet, with a small sac and denticulate limb. Nicaragua. B.M. 4312. Var. *viridifolia*, Hook., has green foliage and larger fls., 1 in. across. B.M. 5195.

**coccinea**, Benth. & Hook. (*Cyrtodeira coccinea*, Hort., B. S. Williams). Lvs. dark metallic green, 3-4 in. long, 2½-3 in. wide.—Free-flowering. Some of the plants sold as *E. metallica*, a name otherwise unknown in botanical literature, probably belong here.

BB. Lvs. a rich dark green.

**fúlgida**, Hook. A beautiful, creeping, much-branched hothouse plant, covered throughout with soft villous pubescence: lvs. ovate to elliptic, wavy and serrate margined, ciliate: fls. axillary, solitary, the calyx prominently 1-sided, the sepals with recurved tips; corolla bright red, the limb deeper colored than the tube which is about 1½ in. long; corolla-lobes rounded and hairy toward the throat. N. S. Amer. B.M. 6136. G.W. 3, p. 161.

WILHELM MILLER.  
N. TAYLOR.†

1404. *Equisetum hiemale*.—Common scouring-rush.

**EQUISETUM** (from the Latin *equus*, horse, and *sela*, bristle). *Equisetáceæ*. Contains the weeds known as horse-tails, or scouring-rushes which are suitable for naturalizing in waste

and wet places and help to hold sandy banks. The following have been advertised by dealers in native plants: *E. arvense*, *E. hiemale* (Fig. 1404), *E. lævigatum*, *E. limosum*, *E. pratense*, *E. robustum*, *E. scirpoides*, *E. sylvaticum*, *E. variegatum*. For descriptions, consult the manuals of native plants. They grow usually in moist or swale-like places. They are flowerless plants, allied to ferns and club-mosses.

Of the species named above, *E. arvense* has been found to have a poisonous effect on grazing stock when it occurs in any quantity in hay or pasturage.

R. C. BENEDICT.†

**ERAGRÓSTIS** (Greek, *er*, spring, and *agrostis*, a grass). *Gramíneæ*. LOVE-GRASS. Annual or perennial grasses with more or less diffuse panicles of small several-flowered compressed spikelets. Some species grown in the open for ornament.

1405. *Eragrostis suaveolens*. ( $\times \frac{1}{4}$ )

From 6 in. to several feet tall: culms simple or often branched; lemmas keeled, 3-nerved, the palea ciliate on the keels.—Species about 100 in warm and temperate regions of both hemispheres.

Some annual species are common weeds, such as *E. megastachya*, Link (*E. major*, Host), STINK- or SNAKE-GRASS, with rather large, ill-smelling spikelets in a compact panicle. Dept. Agric., Div. Agrost. 17:215. *E. pectinacea*, Nees, a native of U. S., is a handsome perennial, with large open panicles of purple spikelets. Well adapted to cult. in sandy soils. Ibid 17:261. *E. obtusa*, Munro (*Briza geniculata*, Thurb.), an annual with showy spikelets, is cult. in Eu., but little known in U. S. V. 3:247.

**abyssinica**, Link (*Poa abyssinica*, Jacq.). TEFF. A branching and spreading leafy annual, 1–3 ft.: panicle large and open, 1 ft. long, the branches capillary; spikelets numerous, loosely 5–9-fl., 3–4 lines long; lemmas acuminate, scaberulous on the tip and nerves. Afr.—This and the following are cult. for ornament, the spreading panicles being used for bouquets. The abundant seed used for making bread in N. E. Afr.

**suavèolens**, Becker (*E. collina*, Trin.). Fig. 1405. A spreading leafy annual, 1–2 ft., differing from the

preceding in the less diffuse panicles, the more compact spikelets and the less acuminate lemmas. W. Asia.

**interrúpta**, Doell (*E. elegans*, Nees). An erect annual, 1–2 ft.: panicle feathery, 1 ft. long, rather narrow, the branches ascending, closely fld. with numerous small spikelets. Brazil.

**amábilis**, Wight & Arn. (*Poa amabilis*, Linn.). Erect or spreading annual, 1–2 ft.: panicles small, 4–6 in., rather compact; spikelets purple, many-fl., 3 lines long, 1 line wide. India.

**máxima**, Baker. An erect, robust annual, 2–3 ft.: blades lanceolate, cordate at base: panicle erect, lax, 6–9 in. long and broad, the pedicels capillary; spikelets oblong,  $\frac{1}{8}$ – $\frac{1}{2}$  in. long. Madagascar.

A. S. HITCHCOCK.

**ERÁNTHEMUM** (Greek, *lovely flower*). *Acanthaceæ*. Tropical shrubs and sub-shrubs, some of which are cultivated chiefly for their foliage and others for their flowers.

Leaves entire or rarely coarsely toothed: fls. white, lilac, rosy or red, borne in various ways; bracts and bractlets narrow, small; corolla-tube long, slender, cylindrical throughout or rarely with a short throat; limb 5-parted; stamens 2; ovules 2 in each cell; seeds 4 or fewer.—Perhaps 30 species. The genus *Dædalacanthus*, although in a different tribe, is separated only by a combination of technical characters, but the garden forms of both genera described in this work are all distinguishable at a glance. For cult., see *Jus-ticia*. Consult *Dædalacanthus* for related species.

A. Fls. purple.

**laxiflórum**, Gray. Height 2–4 ft.: lvs. on the same plant varying greatly in size and shape, those near the fls. 2–3½ in. long, 8–15 lines wide; petioles 2–6 lines long, widest below, at or above the middle, more or less ovate-oblong, obtuse, narrowed at the base: fls. in cymes; stamens 2, perfect, sharp-pointed. Fiji. B.M. 6336.

AA. Fls. pure white.

**tuberculátum**, Hook. Easily told while growing by the many small roundish and rough elevations on the branches: lvs. small,  $\frac{3}{8}$ – $\frac{5}{8}$  in. wide, rarely if ever 1 in. long, broadly elliptical, obtuse or notched, almost sessile: fls. numerous, borne singly in the axils, in summer; corolla-tube very long and slender, 1½ in. long; limb 1 in. across; stamens scarcely exerted. Habitat unknown. B.M. 5405.

AAA. Fls. white, speckled with red-purple.

B. Foliage netted with yellow.

**reticulátum**, Hort. (*E. Schömburgkii*, Lind.). Height 4 ft.: upper lvs. 2–7 in. long, ovate-lanceolate, characteristically netted with yellow; lower lvs. 6–10 in. long, not netted, but the veins prominent and yellow: fls. racemose; corolla speckled with blood-red at the mouth; anthers reddish brown, exerted. Possibly Austral. B.M. 7480. I.H. 26:349.

BB. Foliage not netted with yellow.

**Ándersonii**, Mast. Lvs. lanceolate or elliptic, narrowed into a short stalk: fls. in a spike 6 in. long; lower middle lobe of the corolla larger and speckled with purple. Trinidad. Gn. 45:11. G.Z. 25:49.

The following trade names belong to plants grown chiefly for their foliage. Probably many of them belong in other genera.—*E. albo-marginátum*. Lvs. broadly margined with white and irregularly suffused gray.—*E. atrosanguineum*, Hort. Intro. by W. Bull, 1875. Lvs. large, dark, wine-purple, or blackish crimson, ovate entire, opposite, stalked. Said to endure the hottest sunshine.—*E. cultrátum*. "Lvs. shining, thick, deep-veined."—*E. Dutrebrayianum*, Hort., is supposed to be a garden hybrid. Intro. from France in 1907.—*E. Eldorado*. Lvs. greenish yellow, veins deeper yellow.—*E. igneum*. G.W. 3, p. 159. See *Chamæranthemum*.—*E. Magneanum*, Hort., is recorded as a garden hybrid. Intro. from France 1907. Scarcely known in U. S.—*E. nervum rubrum* presumably a misprint for *nervum rubrum*, has lvs. "irregularly shaped, shaded with light and dark green, and blotched

with yellow, which darkens to reddish purple." Possibly=*Fittonia Verschaffeltii*.—*E. nervosum*=*Dædalacanthus nervosus*, T. Anders.—*E. nigrescens*. Presumably with blackish lvs.—*E. pulchellum*, Hort. and And.—*Dædalacanthus nervosus*, T. Anders.—*E. purpureum*. "Lvs. and sts. dark, lurid purple." Siebrecht & Wadley.—*E. Wattii*, Stapf, is probably the correct name for the plant treated as *Dædalacanthus Wattii*, Bedd. See B.M. 8239. G.C. III. 45:89.

WILHELM MILLER.

N. TAYLOR.†

**ERÁNTHIS** (Greek, *er*, spring, and *anthos*, a flower; from the early opening of the flowers). *Ranunculaceæ*. WINTER ACONITE. Low perennial herbs, grown in open flower-beds because of the very early show of bright flowers; very desirable.

Rootstock tuberous: basal lvs. palmately dissected, 1 st.-lf. sessile or amplexicaul just beneath the large yellow fl.: sepals 5-8, petal-like; petals small, 2-lipped nectaries; stamens numerous: carpels few, stalked, many-ovuled, becoming follicles.—About 7 species, natives of Eu. and Asia. The earliest generic name is *Cammarum* which was given in Hill's British Herbal, p. 47, pl. 7 (1756), but it is not accepted by the "nomina conservanda" of the Vienna code.

Winter aconites are very hardy, and at home in half-shady places, among shrubs or in the border.

Propagated by division of roots. The place in which the tubers are planted should be marked during the summer, when the foliage is dead.

*hyemalis*, Salisb. (*Helleborus hyemalis*, Linn.). Fig. 1406. Erect, 5-8 in.: basal lvs. long-petioled: involucre 12-15-parted, the bright yellow fls. always sessile; anthers oblong. Jan.-March, or as soon as frost is out of the ground. Naturalized from Eu. B.M. 3. Mn. 8, p. 43. G.C. II. 11:245. G. 1: 628; 34:277.

Var. *cilicica*, Huth. (*E. cilicica*, Schott & Kotschy). Much like the above: involucre of deeper

and more numerous lobes; anthers ovate instead of oblong; sepals broader, being about  $\frac{1}{2}$  in. across: follicles always straight. Season a few weeks later. G.C. III. 13:266. G.M. 49:180.—The sts., when grown in gardens, said to be red-brown. Roots of this were first sent to England from its native home near Smyrna in 1892. Rare in Amer.

*sibirica*, DC. Much dwarfer, seldom over 3-4 in. high: fls. bright yellow, a little smaller than those of *E. hyemalis*, 5-sepaled. Siberia.

K. C. DAVIS.

**ERCÍLLA** (Peruvian name). *Phytolaccææ*. One twining shrub from Peru and Chile, apparently not in the trade but sometimes cult. in this country for its dense spikes of pale purple fls. and dark purple berries. By some it is united with *Phytolacca*, from which it differs in habit, the coriaceous evergreen lvs., larger bracteoles and technical characters of the fl. *E. volubilis*, Juss. (*E. spicata*, Moq. *Bridgesia spicata*, Hook. & Arn. *Phytolacca volubilis*, Heiml.), has alternate, petioled, ovate-cordate or oblong or orbicular lvs. 1-2 in. long: fls. perfect, in spikes 1-1 $\frac{3}{4}$  in. long, the perianth 5-parted, segms. oblong and obtuse; stamens 8-10, with filiform fleshy filaments, the alternate ones being shorter: carpels 4-8, somewhat impressed in the torus, becoming as many ovoid berries. G.C. II. 9:653. Said to be excellent for covering walls, and climbs by aerial rootlets. It is easily prop. by seeds and cuttings.

L. H. B.

**EREMOCÍTRUS** (Greek, *desert* and *Citrus*). *Rutaceæ*, tribe *Citrææ*. AUSTRALIAN DESERT KUMQUAT. Spiny shrub or small tree: lvs. small, simple or emarginate, thick and leathery, alike on both sides; spines single, long, slender, axillary: fls. small, 4- (rarely 3- or 5-) merous, white, fragrant, borne singly; or 2 or 3 together in the axils of the lvs.; stamens free, 4 times as numerous as the petals: frs. small, subglobose, oblate or pyriform, yellow, with a thin fleshy peel like that of a lime, 4- (rarely 3-5-) celled with 1 or 2 seeds in each cell; cells containing stalked subglobose pulp-vesicles filled with a pleasant acid juice.—Only 1 species of this subtropical Australian genus is known.

*glauca*, Swingle (*Triphasia glauca*, Lindl. *Atalántia glauca*, Benth.). A shrub or small tree bearing edible frs. and occurring in Queensland and New S. Wales, Austral., in subtropical regions subject to severe cold and extreme drought. The lvs. of this plant are small (1-1 $\frac{1}{2}$  ×  $\frac{1}{8}$ - $\frac{1}{4}$  in.), emarginate, and show marked drought-resistant adaptations; both faces of the lvs. show palisade cells, and stomates at the bottom of deep pits; the long and slender spines are borne singly in the axils of the lvs. (see Fig. 1407): frs. subglobose, flattened or slightly pyriform (see Fig. 1408), usually 4-celled and containing globose stalked pulp-vesicles (see Fig. 1408); seeds small, with a longitudinally furrowed and rugose testa. Yearbook Dept. Agric., 1911, pl. 45, fig. 1. Jour. Agric. Research, U. S. Dept. Agric. vol. 2, pp. 85-100, figs. 1-7, pl. 8.—The frs. of this species are used by the settlers in Austral. for jam and pickles and ade is made from the juice. The Australian desert kumquat is the hardiest evergreen citrus fr. known besides being the only one showing pronounced drought-resistant adaptations; it bears in the wild state edible frs. with a pleasant acid juice and a mild-flavored peel. These characteristics make this plant very promising for use in breeding new types of hardy drought-resistant citrus frs. It has been intro. into the U. S. by the Dept. of Agric., and is now growing in the greenhouse of the Dept. of Agric. and in the southern and western states. It can be grafted on the common citrus fruit trees, and can in turn be used as stocks for them.

WALTER T. SWINGLE.

**EREMÓSPATHA** (*solitary spathe*). *Palmaceæ*. Above a half-dozen Trop. African climbing palms, with long slender ringed sts. and pinnate lvs. Apparently none is in the trade. The fls. are perfect; calyx 3-toothed, campanulate; corolla urn-shaped, with 3 short lobes; stamens 6, with broad connate filaments; ovary 3-celled, and stigmas 3: fr. berry-like: lfts. alternate and opposite; rachis spiny, with a long tendril at end.

1408. Fruit of *Eremocitrus glauca*, entire and in cross-section, showing stalked globose pulp-vesicles and furrowed seeds. (Natural size)

1407. Spiny twig of young seedling of *Eremocitrus glauca*. (×  $\frac{1}{2}$ )

**EREMÓSTACHYS** (*deserted* or *solitary spikes*). *Labiataæ*. Outdoor perennial, apparently only 1 species of the 50 or so in the genus being in commercial cult. The genus is allied to *Leonotis* and *Phlomis*, and the species are from Cent. and W.

1406. *Eranthis hyemalis*.

Asia. Erect herbs, with the lvs. mostly radical, large, toothed or cut-pinnatifid; st.-lvs. small, passing into floral bracts: fls. often ochroleucous, in many-ld. whorls in terminal and axillary spikes; corolla-tube included within the calyx; upper lip of corolla erect and hooded, bearded inside; lower lip 3-lobed and the middle lobe largest; stamens 4, with connivent anthers. *E. laciniata*, Bunge, is catalogued abroad. Nearly simple, 12-20 in.: lvs. pinnatisect, the lobes again pinnatifid: fls. yellow or ochroleucous, in midsummer. Asia Minor.—Said to be an attractive perennial. *E. superba*, Royle, reported from Eu., has a strict st., unbranched, 2 ft., root-lvs. pinnatisect, with segms. lobed, forming a rosette: fls. deep primrose-yellow in woolly heads to 6 in. long and 4 in. broad, showy. W. Himalaya.

L. H. B.

**EREMURUS** (Greek name, probably referring to their tall and striking aspect in solitary and desert places). *Liliacæ*. These hardy desert plants, when in flower with their great flower-stalks taller than a man and crowned with a spike of flowers from 1 to 4 feet long, are amongst the most striking objects in the choicer gardens of the North and East.

Root clusters of fleshy fibers: lvs. all from the root, in dense rosettes, long and linear: fls. white, yellow or rosy; perianth bell-shaped or more widely spreading, withering and persisting or finally dropping away; segms. 6, distinct or very slightly united at the base; stamens 6; ovary 3-celled; seeds 1-4 in each cell, 3-angled.—About 20 species, from the mountains of W. and Cent. Asia.

Probably *E. robustus* and *E. himalaicus* are the hardest of all the tall desert-inhabiting plants of the lily family—a family including the poker plant, the aloes, the yuccas, and many others that are not so tall and striking in appearance or else too tender to grow outdoors in the North. Large specimens of *E. robustus* will annually produce a flower-stalk 8 feet or more high, with racemes 4 feet long, remaining in bloom for a month. After flowering the leaves disappear entirely, but early in spring they reappear, and should then be covered with a box or barrel, to protect the forming flower-stalk from late frosts. A mound of ashes over the crown in winter is advisable, or a box with watertight top filled with dry leaves. Both species like a rich soil, moist but well drained, and plenty of water in the flowering period, but none afterwards. Propagation is by division, or slowly by seeds. Large plants are expensive, but they can sometimes be secured large enough to flower within a year or so of purchase. It tries one's patience to wait for seedlings to reach flowering size. The flowers look like small stars. (W. C. Egan.)

A. Fls. rosy.

B. Lvs. linear-ligulate.

**robustus**, Regel. Root-fibers thick and fleshy: lvs. glaucous, glabrous, linear-ligulate, 2 ft. long,  $1\frac{1}{2}$ -2 in. wide, roughish on the margin, with minute recurved teeth: raceme 4-4½ in. wide; stamens about as long as the perianth. Turkestan. B.M. 6726. Gng. 6:52, 324. Gn. 46, p. 335. Mn. 8, p. 123. J.H. III. 29:267. Gt. 61, p. 366. G.C. III. 28:228; 30:426. Var. *álbus*, Hort. Stronger and pure white.—May be grouped in the hardy perennial border with bold effect.

BB. Lvs. ovate-lanceolate.

**Élwesii**, Mich. (*E. Elwesianus*, Hort.). Lvs. light green, ovate-lanceolate, obtuse, flat, not at all rough at the margin, shorter than in *E. robustus*, nearly triangular, even more glaucous, and beginning to decay at the time of flowering: perianth-segms. with a band of deeper color down the middle. Habitat(?). R.H. 1897:280. Gn. 54, p. 99. G.C. III. 24:137; 33:381. G.M. 44:321.—Intro. by Leichtlin as *D. robustus* var. *Elwesii*.

AA. Fls. white.

**himalaicus**, Baker. Fig. 1409. Root-fibers thick and fleshy: lvs. 9-12, ligulate, firm, persistent, 1-1½ ft. long, 6-15 lines wide above the middle: raceme 3-3½ in. wide; stamens about as long as the perianth. Himalayas. B.M. 7076. Gn. 49, p. 131. G.C. II. 16:49. G.M. 44:321; 52:631 (as *E. Elwesii*.)

**Ólgæ**, Regel. Lvs. narrow, glabrous, but with rough margins, about 8-12 in. long and 7-8 lines broad: fls. in a dense raceme, spreading; the white petals with a single brownish nerve down the center. Turkestan. Var. *álbus*, Hort., a white-fl. form is known.

AAA. Fls. some shade of yellow.

B. Color light yellow.

**spectabilis**, Bieb. Root-fibers thick and fleshy: lvs. 6-15, lorate, slightly glaucous, 12-18 in. long, 6-12 lines wide above the middle, noticeably narrowed at the base: raceme 1-1½ ft. long, 2 in. wide; stamens orange, finally twice as long as the perianth. Asia Minor, Persia. B.M. 4870.

BB. Color pure yellow or orange.

**Búngei**, Baker. Lvs. contemporary with the fls., linear, 1 ft. long, less than 3 lines wide: raceme 4-5 in. long, 2 in. wide; stamens finally twice as long as the perianth. Persia. G. 19:31. G.L. 20:155. Gn. 60, p. 53; 66, p. 150. Var. **magnificus**, Hort. A larger form than the type and with brighter yellow fls. Var. **præcox**, Hort. An early flowering more slender form than the type, the fls. smaller and loosely scattered on the spike. Var. **citrinus**, Hort. "More robust than the type and with larger citron-yellow fls."

BBB. Color orange.

**aurantiacus**, Baker. Closely allied to *E. Bungei*, but live plants have less acutely keeled lvs.: root-fibers tapering upward, and orange fls. and stamens. Bokhara, Turkestan. B.M. 113.

During recent years many beautiful hybrid plants have been intro. into cult., often under some specific name which gives no indication of the parentage. Of these the following are known and the parents are indicated when possible.—*E. isabellinus*, Vilm. A hybrid between *E. Bungei* and *E. Ólgæ*. Fls. large, apricot-rose.—*E. Micheliæus*, Hort., is supposed to be a hybrid between *E. Warei* and *E. Bungei*. G.C. III. 40:83, desc.—*E. Tubergemii*, Hort. A hybrid, crossed in Holland between *E. himalaicus* and *E. Bungei*.—*E. vedrariensis*, Hort.—*E. robustus* × *E. spectabilis*? R.H. 1907, p. 229.—*E. Warei*, Hort., is supposed to be a natural Eastern Asiatic hybrid between *E. Bungei* and *E. Ólgæ*. It is described as growing in ordinary seasons about 8 ft. high. The fls. are less bright than in *E. Bungei*, and in rootstock it resembles the later-flowering *E. Ólgæ*. Gn. W. 22: suppl. May 27.

WILHELM MILLER.

N. TAYLOR.†

**ÉRIA** (from Greek for *wool*, as the leaves of some species are downy or woolly). *Orchidacæ*. About 100 species of tropical Asian orchids allied to *Dendrobium* but with eight rather than two or four pollinia, of most diverse habit, and very little in cultivation outside the

1409. Eremurus himalaicus.

collections of botanic gardens and fanciers, being mostly curious and botanical rather than beautiful. They require greenhouse treatment, after the manner of stanhopeas.

**ERIÁNTHUS** (Greek, *erion*, wool, and *anthos*, a flower). *Gramíneæ*. PLUME-GRASS. Tall reed-like ornamental perennials with large woolly plume-like inflorescence.

Spikelets in pairs, one sessile, the other pedicellate, as in *Andropogon*, arranged in spikes, and these in a large terminal panicle, clothed with long hairs, especially around the base, the fertile lemma awned.—Species about 18, warmer regions of both hemispheres.

**Ravennæ**, Beauv. PLUME-GRASS. RAVENNA-GRASS. HARDY PAMPAS-GRASS. Fig. 1410. Three to 12 ft.: blades  $\frac{1}{2}$  in. wide, narrowed into a firm rough point; panicle or plume as much as 2 ft. long. S. Eu. Gn. 54, p. 496. R.H. 1890, p. 546. V. 3:247.—This is one of the best of the stout and tall perennial grasses. It thrives in light and open places in well-drained soils, and makes great clumps, when well established sometimes producing as many as 40 or 50 heads. Hardy in latitude of New York City.

A. S. HITCHCOCK.

**ERICA** (practically meaningless; probably not from *ereiko*, to break, as commonly stated). *Ericáceæ*. HEATH. This is the genus that the gardener usually means by "heath." The heath or heather of English literature and history belongs to the closely allied genus *Calluna*. The next most important group of cultivated "heaths" is *Epacris*, which, however, belongs to a different family.

Ericas are perennial woody plants from 6 in. to 12 ft. or more, usually much branched; lvs. in whorls of 3-6, very rarely flat, usually 3-sided and with revolute margins that are sometimes connate with the under side; infl. usually terminal or sometimes axillary, very seldom actually, though often apparently, racemose; calyx free, 4-parted; corolla hypogynous, white, rosy or sometimes yellow, usually early deciduous, variously shaped, the commonest forms (in cult.) being bell-shaped, tubular and ventricose, usually 4-lobed; stamens 8; ovary sessile or rarely stalked, 4-celled, rarely 8-celled, with 2- $\infty$  ovules in each cell; fr. a 4-valved caps., with minute seeds.—About 500 species, mostly from S. Afr. and the Medit. region, nine-tenths from the former. There are many hybrids and horticultural forms. So far as the S. African species are concerned, the latest monograph is that of Guthrie and Bolus, which has served as the basis for the treatment below.

Only a few of the European heaths are hardy in America, and there are no native heaths at all in this hemisphere. Of about fourteen kinds of *Erica* grown outdoors in Europe to produce large showy masses, only three are hardy here, and it is safest to cover these with evergreen boughs in winter. Two others (*E. mediterranea* and *E. lusitanica*) are grown under glass somewhat but they are probably hardy, with protection, from New York southward. The tree heath of southern Europe (*E. arborea*) will probably never be a feature of our southern landscapes. The heath that is naturalized in places from Rhode Island to Newfoundland

is *Calluna vulgaris* (which see); and this is sometimes advertised as *Erica vulgaris*.

The halcyon days of the heaths were from about 1806 (when the English took the Cape of Good Hope) until the middle of the century. Andrews' colored engravings of heaths (1809)\* marks the first flush of their popularity. Practically, if not absolutely, all the heaths that are grown on a large scale have been developed from the South African species. The old English gardeners still lament the glorious days when the hard-wooded plants of Australia and the Cape formed the chief feature of European indoor horticulture. They complain that the present generation is not willing to give them the care they deserve. This is especially true of America. In America, heaths are of minor importance, even at Easter, and the kind grown most extensively for Christmas seems to be *E. melanthera*.

The great trouble with heaths is the immense amount of care they need. Few, if any, classes of plants require more attention. Hence the growing of heaths for the market is extremely specialized, and there the American retail catalogues only rarely offer more than one species. Nevertheless, all the kinds described below are grown commercially, and are of the first importance in the genus. The stock is largely imported from England. Germany has a very different set of varieties, and France still another, and there are few cases among cultivated plants showing so great a difference in the three countries. The risks of importation are considerable, and the tendencies toward American independence in this line seem to be gaining. Another difficulty in heath-culture is the poor quality of peat obtainable in America. In England the peat is more fibrous, and has been formed in past ages largely by the decay of the native heather.

The soft-wooded kinds are the ones most grown. The hard-wooded sorts require a longer period of growth and more thorough ripening of the wood. Apparently only one yellow-flowered heath is cultivated in America, *E. Cavendishiana* which is a hybrid species about which little is known. See supplementary list (p. 1132).

In general, the ericas do not grow well in this climate on account of the extreme heat of the summer months, but some varieties grow and flower even better here than in Europe. The

choice of the soil is very important. A light peat, mixed with sharp coarse sand is about the best we can get here. After flowering, the plants should always be cut down to keep them bushy at the base and well shaped. They will then receive a good repotting, always using very clean pots and plenty of drainage. Cuttings are made from December to April, preferably from young plants, the tender shoots about 1 inch in length being best. These are planted firmly in a pan filled with clean fine sand, and covered with a bell-glass, or in a box covered tightly with a pane of glass. Bottom heat is not necessary. When rooted, the cuttings should be potted in small pots, and when well started should be given as much air as possible. It is well to bring the ericas out of the greenhouse as early in the spring as possible. The pots should be plunged in a good location, where plenty of air and

1410. *Erianthus Ravennæ*.

sunlight can be had. They should be wintered in a greenhouse extremely well ventilated, and a temperature not higher than 40° to 45° F. When in bud the plants should not be allowed to dry out too much. One drying might be enough to cause the loss of all the buds. Very often the heaths are attacked by a disease similar to mildew, brought on by an excess of humidity in the air. As this disease is very contagious, it is well, as soon as noticed, to use sulfur in powder or sulfate of copper in solution until the plants are rid of it (Louis Dupuy).

## KEY TO THE SPECIES.

- A. Heaths hardy, European, or hardy with protection from New York southward.  
B. Lvs. and calyx-segms. ciliate: stamens included.  
C. Fls. in spike-like clusters. . . . . 1. ciliaris  
CC. Fls. in umbel-like clusters. . . . . 2. Tetralix  
BB. Lvs. and calyx-segms. glabrous.  
C. Anthers usually exerted well beyond the corolla-tube.  
D. Fls. usually solitary and lateral, rose-colored. . . . . 3. mediterranea  
DD. Fls. clustered, pink, usually all lateral. . . . . 4. carnea  
DDD. Fls. all clustered at the ends of the branches. . . . . 5. vagans  
CC. Anthers included in the corolla-tube.  
D. Fls. rose-violet or purplish.  
E. The lvs. verticillate in 3's. . . . . 6. cinerea  
EE. The lvs. verticillate in 4's. . . . . 7. stricta  
DD. Fls. pale rose, in broad panicles. . . . . 8. lusitanica  
AA. Heaths tender, S. African, always grown under glass in Amer.  
B. Fls. mostly showy, petal-like, scarcely greenish or sepal-like.  
C. Corolla tubular, the limb not spreading.  
D. Length of fls. usually more than 6 lines, in cult. specimens umbellate. . . . . 9. verticillata  
DD. Length of fls. usually 10-12 lines, in 2's or 3's. . . . . 10. hyemalis  
CC. Corolla various, not tubular, the limb often spreading.  
D. The corolla-segms. spreading, the tube mostly elongate.  
E. Length of corolla 6-8 lines; segms. ovate, acute. . . . . 11. ventricosa  
EE. Length of corolla 3-4 lines; segms. ovate or sub-orbicular. . . . . 12. præstans  
DD. The corolla-segms. usually not spreading, the tube rarely over 4 lines long.  
E. Lvs. channeled.  
F. The lvs. in 3's. . . . . 13. sicæfolia  
FF. The lvs. in 4's. . . . . 14. propendens  
EE. Lvs. not channeled, more or less open-backed and spreading.  
F. Infl. variable, often terminal and axillary on the same plant. . . . . 15. fiacca  
FF. Infl. always terminal.

- G. Sepals about as long as the corolla-tube.  
H. Lvs. rough or tuberculate. . . . . 16. turrigera  
HH. Lvs. not rough.  
I. The lvs. glabrous. . . . . 17. gracilis  
II. The lvs. usually pubescent. . . . . 18. persoluta  
GG. Sepals about half as long as the corolla-tube. . . . . 19. formosa  
BB. Fls. not so showy, calyx-like, the calyx often colored also.  
C. Lvs. in 3's: sepals colored. . . . . 20. melanthera  
CC. Lvs. opposite: sepals green. . . . . 21. fragrans

1. *ciliaris*, Linn. A much-branched nearly hardy shrub, 10-20 in. tall, the branches usually glandular: lvs. small, but not as in typical heaths, ovate, mucronate: fls. about 4 lines long, or more, purplish, in spike-like, lateral clusters. Eu. June-Sept. B.M. 8443.

2. *Tetralix*, Linn. BELL HEATHER. CROSS-LEAVED HEATH. Lvs. in 4's, margin folded back: fls. rosy; sepals ovate-lanceolate, ciliate; anthers awl-shaped or awned, included; ovary with short, soft hairs. W. Eu.—Foliage grayish. Height in England 6-12 in. With Manning, at Reading, Mass., about 8 in.

3. *mediterranea*, Linn. (*E. carnea* var. *occidentalis*, Benth.). Fig. 1411. This is considered by Bentham a western form of *E. carnea* (No. 4), with a little smaller fls., corolla a trifle wider at the apex, and anthers shortly exerted instead of included. *E. mediterranea* of the trade is hardy in England, and perhaps second only to *E. carnea* in popularity there. In Amer. it seems to be cult. only under glass but should be hardy from N. Y. southward with protection. B.M. 471. Gn. 54:263; 55, p. 403; 61, p. 431. G.M. 45:261; 55:315. Var. *alba*, a white-fl. form is known. Gn. 59, p. 94.

4. *carnea*, Linn. (*E. herbacea*, Linn.). Height 6 in.: lvs. in 4's: infl. lateral; corolla broadly bell-shaped; anthers exerted; ovary glabrous. March-May. Alps. L.B.C. 15:1452. B.M. 11. Gn. 54:6 (a charming picture).—The bright rosy-fl. form is the best and most striking. There are pale red and pure white varieties. The most popular of all hardy ericas. Very easily prop. by division. *E. mediterranea* var. *hybrida*, Hort., is said to be a cross with *E. carnea*, and in England thriving almost as well in loam as in peat. See Gn. 54:262; 55, p. 127; 61, p. 399; 72, p. 176. G.M. 50:39. J.H. III. 51:293.

5. *vagans*, Linn. CORNISH HEATH. Fig. 1412. Lvs. in 4's or 5's: sepals small, ovate, obtuse; corolla ovate-bell-shaped; anthers ovate-oblong, 2-parted, exerted; ovary not hairy. W. Eu. and Medit.—Fls. pale purplish red. Grows 3-4 ft. in England; 1 ft. with J. W. Manning, Reading, Mass. Var. *alba* has white fls. Var. *capitata*, grows 1-2 ft. high with Meehan at Germantown, Pa., and has "small whitish fls. with a purplish tip." F.E. 22:685.

6. *cinerea*, Linn. A twisted and much-branched shrub, 8-15 in. high: lvs. verticillate, in 3's, narrow, glabrous, and usually not over 3 lines long: fls. showy, rose-violet, in usually verticillate clusters; corolla much contracted at apex, the lobes reflexed. June-Sept. Eu. Var. *alba*, Hort., a white-fl. form, and var. *coccinea*, Hort., a scarlet form, are both in the trade. Gn. 61, p.

1411. *Erica mediterranea*.

433.—Hardy in U. S., with a little protection, from N. Y. southward.

7. *stricta*, Don. CORSICAN HEATH. Lvs. in 4's, a little more erect than in No. 2: sepals lanceolate, obtuse; corolla ovoid-oblong, narrowed at the throat; anthers awl-shaped or awned, included; fls. rosy purple; ovary densely covered with long, rough hairs. Corsica.—Summer. Attains 4 ft. in Eng., but grows 1–2 ft. high with Meehan, at Germantown, Pa. Branches strict, rigid.

8. *lusitânica*, Rudolph (*E. condonodes*, Lindl.). SPANISH HEATH. Branches tomentose-pubescent; lvs. glabrous and ovary glabrous: fls. pale rose, in broad panicles. W. Eu. B.R. 1698. G.C. II. 7:463; III. 19:487; 35:91. I.H. 43, p. 321. Gn. 54:263; 55, p. 125; 67, p. 328. B.M. 8018. G. 21:384; 30:130.—Hardy in England, but in U. S. only south of N. Y., and then must be protected.

9. *verticillata*, Berg. An erect shrub, 4–6 ft., with lvs. 4–6 in a whorl: lvs. densely imbricate, erect or spreading: fls. mostly in 4's in wild specimens, but, according to Andrews, umbellately 3–10-fld. in cult.; corolla tubular, hairy, usually straight, bright rosy-scarlet, and very showy: caps. unique in splitting into 8 valves. Andr. Heathy, 58.

10. *hyemalis*, Hort. Fig. 1413. Written also *hiemalis*. Watson thinks it may be a winter-flowering form of *E. perspicua*, figured in L.B.C. 2:102 and 18:1778 as *E. Linnaëana*. Fls. rosy pink, tipped white. Var. *alba* has white fls. With L. Dupuy, Whitestone, L. I., it flowers in Sept. G.F. 5:137. Gn. 41:420. G. 25:567. H. D. Darlington says it is very distinct from *E. perspicua*.

11. *ventricosa*, Thunb. Lvs. in 4's, incurved to spreading, with pilose margins: infl. terminal; sepals keeled; anthers with 2 very short ears, or awned, included; ovary glabrous. B.M. 350. L.B.C. 5:431. G. 9:565; 26:239. Var. *grandiflora*, with tubes over  $\frac{1}{2}$  in. long. L.B.C. 10:945 (as *E. prægnaans*). The following varieties are reported: *Bothwelliana*, *breviflora*, *cárnea rosea*, *cintra*, *hirsuta*, *alba*, *magnífica*, *superba*, *tricolor*. See R.H. 1858, p. 450; 1880:50. Gn. 45, p. 87. A.F. 10:1111. F.E. 9:333.

12. *præstans*, Andr. (*E. Parmetiærii*, Lodd.). Lvs. in 4's, somewhat incurved; bracts crowded: fls. nearly sessile, white, faintly flushed pink at base, in terminal groups of 4 or more; sepals ovate, rough-margined; anthers scarcely acute. Sept. Varieties are pictured under various names in L.B.C., plates 154, 197, 1695, and 1804.

13. *sicáfolia*, Salisb. (*E. pygmæa*, Andr. and Hort.). Dwarf cushiony heath, perhaps best treated in the alpine garden, 4–8 in. high: branches ascending, nearly glabrous: lvs. in whorls of 3, linear-acuminate,  $2\frac{1}{2}$ –5

lines long: fls. in 3's, the corolla dark purple, its segms. ciliate. L.B.C. 5:468. B.M. 2263.

14. *propendens*, Andr. An erect sub-shrub, 10–18 in. high, the branches nearly straight, the younger pubescent: lvs. in 4's, linear and usually 3-sided, ciliate, or sometimes glabrous: fls. 1–4 in a cluster, the corolla red, broadly bell-shaped and hairy, about  $\frac{1}{3}$ – $\frac{1}{2}$  in. long; ovary 4–8-celled, rough but not hairy. L.B.C. 1:63. B.M. 2140. Andr. Heathy, 141. G. 25:137. G.C. III. 32:278, 279. Gn.W. 21:759. J.H. III. 47:543.

15. *flacca*, E. Mey. (*E. ciliàris*, Thunb., not of Hort.). An erect shrub, usually branched, but not diffuse, the branches pubescent or glandular hairy: lvs. in 3's, rarely in 4's on the same plant, spreading, usually "linear, as if subterete," the margins revolute,  $1\frac{1}{2}$ – $2\frac{1}{2}$  lines long: fls. in 3's, the corolla bell-shaped to tubular, the segms. about a third as long as the tube; ovary sometimes hairy on the top.

16. *turrigera*, Salisb. (*E. cupressina*, Forbes). Lvs. glabrous, sub-ciliate or naked: infl. terminal; fls. pedicelled, in 1's to 4's; bracts remote; sepals finally reflexed; sinuses of the corolla acute, narrow. Probably a hybrid, cult. since 1802. F.E. 9:333. A.F. 15:

1175. Gng. 9:35 (the last two as *E. cupressina*).

17. *gracilis*, Salisb. Lvs. in 4's, somewhat erect; bracts remote: sepals smaller, lanceolate; anthers with a short, sharp point. L.B.C. 3:244 (pale violet). G. 25:602. Gn. 76, p. 11. "Fls. purplish red." Var. *autumnalis*, Hort. Fls. Sept. Var. *vernalis*, Hort. Fls. in Oct. and Nov.

18. *persoluta*, Linn. Fig. 1414. Essentially a white-fld. and very variable species, particularly as regards hairiness: lvs. erect or spreading, hirsute or glabrous: corolla small, originally  $1\frac{1}{2}$  lines long; lobes ovate, 2–3 times shorter than the tube, the sinuses acute, narrow. S. Afr. The numerous varieties Bentham found impossible to separate either in the wild or in cult. Var. *hispidula*, Benth. Slightly hirsute: lvs.  $2\frac{1}{2}$ –3 lines long, rough; anthers sub-ovate. Var. *lævis*, Benth. Lvs. shorter, blunter, often appressed, glabrous: anthers subglobose. Var. *subcárnea*, Benth., has the corolla lobes more evident. To this last variety Bentham seems to refer most of the horticultural varieties cult. under the name of *E. persoluta*. *E. assurgens*, Link, he refers to the first variety; *E. cáffra* of Linnaeus to the first, but of L.B.C. 2:196 (and the trade?) to the second. *E. regérminans* of Linnaeus is a distinct species (figured in L.B.C. 17:1614 as *E. Smithiana*); of the trade=*E. persoluta* var. *hispidula*; of L.B.C. 18:1728=*E. persoluta* var. *subcárnea*. Flowers in Feb and March, while other related species mostly flower in March and April.

1412. *Erica vagans*. ( $\times \frac{1}{4}$ )

1413. *Erica hyemalis*. Great numbers of this heath are sold in London every Christmas.

19. *formosa*, Thunb. (*E. grandinosa*, Hort.). Erect shrub, 1-2 ft., the branches hairy, covered with lvs. in whorls of 3: lvs. glossy, channeled, the younger ciliate, about  $1\frac{1}{2}$  lines long: fls. in 3's, the corolla white, with 8 longitudinal channels, sticky. Andr. Heathy 265.

1414. A form of *Erica persoluta*.

rous or slightly bristly at the tip. B.M. 2181. L.B.C. 3:288.

The following are mostly kinds that have been grown successfully in small quantities in this country but appear not to be advertised in American trade catalogues. H=hard-wooded; the rest are soft-wooded. S. Afr., unless stated. Aside from these, *E. scoparia*, Linn., of S. Eu., is sometimes listed: 2-3 ft., glabrous: lvs. in 3's: fls. greenish, in 1-sided racemes; calyx-lobes about half the length of the subglobose corolla. *E. capensis* also appears, but it is apparently only a catalogue name.

*E. ampullacea*, Curt. Lvs. ciliate, mucronate: bracts colored; fls. mostly in 4's: corolla ventricose, very sticky, typically white, lined with red; limb spreading, white. Var. *ribra* is the only form cult. B.M. 303. L.B.C. 6:508. H.—*E. arborea* var. *alpina*, W. I. Beau. An alpine variety, grown only at Kew. It is a stiff erect bush with tiny white fls. in plume-like clusters. Gn. 75, p. 384.—*E. aristata*, Andr. Readily distinguished by the long bristle which ends the lvs.: lvs. recurved: fls. in 4's; sepals keeled with red; corolla sticky, 1 in. long, ventricose, but with not so long and narrow a neck as in *E. ampullacea*. B.M. 1249. L.B.C. 1:73. H.—*E. barbata*, Andr. Bristly and glandular-pubescent: lvs. in 4's: corolla urn-shaped, villous; ovary villous. L.B.C. 2:124.—*E. Boniédina*, Lodd. Lvs. in 4's to 6's: infl. axillary; corolla tubular, slightly inflated; limb erect or scarcely open. L.B.C. 9:842.—*E. Burnettii*, Hort. Hybrid. F.S. 8:845.—*E. Cavendishiana*, Hort. (*E. Cavendishii*, Hort.). Hybrid of *E. depressa* × *E. Patersonii*. Lvs. in 4's, margins revolute: fls. in 2's to 4's; corolla tubular; stamens included; anthers awned. P.M. 13:3. G.C. 1845, p. 435; II. 18:213; 20:597. F.S. 2:142. A.F. 12:1143. Gng. 5:331. C.L.A. 7:180. G. 6:489; 10:243.—*E. conspicua*, Soland., is a species with club-shaped, villous fls. and villous lvs. in 4's. Var. *splendens*, Klotzsch, with the lvs. and sepals shining green and pubescent corollas, includes *E. elata*, Andr. L.B.C. 18:1788.—*E. cylindrica*, Andr. and Hort. Important hybrid of unknown parentage, cult. since 1800. Lvs. in 4's: fls. nearly sessile; corolla 1 in. long, brilliant rosy red, with a faint circle of dull blue about two-thirds of the way from the base; anthers awned, included; ovary glabrous. L.B.C. 18:1734. R.H. 1859, p. 42.—Fls. very showy and unusually long. The oldest *E. cylindrica*. That of Wendland is a yellow-fl. species unknown to cult.—*E. Devoniana*, Hort. Hybrid. Fls. rich purple. H.—*E. elata*, Andr.—*E. conspicua* var. *splendens*.—*E. Irbiana*, Andr. Allied to *E. ampullacea*, but with corolla narrower at the base and tapering with perfect regularity to just below the limb, where it has a prominent red bulge. It is also distinctly lined with red, and the sepals are green, although the bracts are colored, as in *E. ampullacea*. L.B.C. 9:816. H.—*E. nigrescens* is presumably *E. melanthera* (H. D. Darlington).—*E. pallida*. A confused name. The oldest plant of this name is Salisbury's, which has an urn-shaped corolla, fls. often in 3's, pubescent and hirsute branches and lvs. in 3's. L.B.C. 1:72 (as *E. pura*). *E. pallida* of the trade is probably the tubular-fl. hybrid of Loddiges in L.B.C. 14:1355, which has axillary and terminal fls., and lvs. in 4's to 6's.—*E. perspicua*, Wendl., has a tubular or slightly club-shaped corolla, lvs. in 4's, pubescent or rough-hairy, and fls. in 1's to 3's, but the plant in the trade is probably *E. perspicuoides*, Forbes, a hybrid, with longer and woollier hairs, fls. somewhat in umbels, nearly 1 in. long. Only var. *erecta* is grown here.—*E. Syndriana* is grown by Louis Dupuy.—*E. transiens*, Andr. Perhaps the first of all the garden hybrids between *E. tubiflora* and *E. ventricosa*. Lvs. rigid, with or without long, soft, red hairs: fls. in umbel-like heads; bracts remote: corolla rosy, 8-9 lines long; tube narrowly ventricose, pubescent limb short, spreading; ovary sessile. Andr. Heaths, 295. Bentham considers this a synonym of *E. spuria*, Andr. Heaths, 60. Schultheis

says "it is the finest erica grown; a poor propagator but good grower. Takes 3 months to root."—*E. tricolor* is perhaps the most confused name in the genus, and apparently one of the important kinds abroad, where it has many varieties and synonyms. In the trade it seems to stand for a handsome heath, with lvs. in 4's, distinctly ciliate and terminated by a bristle: fls. in umbels of 8-10, 1 in. long, a little too inflated at the base for the typical tubular form, rosy at the base, then white, then green, and then suddenly constricted into a short neck; pedicels red and exceptionally long. This description is from L.B.C. 12:1105 (as *E. eximia*), one of the earliest pictures of these charming hybrids which Bentham refers to the hybrid *E. aristella*, Forbes.—*E. Wilmorea*, Knowles & Weste. (*E. Wilmorea* and *Wilmorea*, Hort.). Hybrid: corolla tubular, bulged below the lobes, slightly velvety-hairy: fls. in 1's to 3's, rosy, tipped white. R.H. 1892, p. 202. A.F. 4:251. G.C. III. 19:201. A.G. 21:869. Var. *glauca*, Carr., has nearly glaucous foliage. Var. *calyculata*, Carr., has a large additional calyx. R.H. 1892, p. 203.

WILHELM MILLER.  
N. TAYLOR.†

**ERIGENIA** (Greek, *spring-born*). *Umbelliferae*. HARBINGER-OF-SPRING. A monotypic genus of E. N. Amer. *E. bulbosa*, Nutt., is low (4-10 in.), nearly stemless, hardy, from a deep-lying tuber, with ternately decomposed lvs. and small umbels of minute white fls. A few plants may have been sold by collectors and dealers in native plants, but it is not a cult. plant. It grows in rich deciduous woods and clearings.

**ERIGERON** (Greek, *old man in spring*; some of the early kinds are somewhat hoary). *Compositae*. FLEABANE. Hardy border plants, suggesting native asters, but blooming much earlier, growing in tufts like the English daisy, though usually from 9 inches to 2 feet high.

Stem-lvs. entire or toothed: fls. solitary, or in corymbs or panicles; rays in 2 or more series, mostly rose, violet or purple, rarely cream-colored or white, and one kind has splendid orange fls.; involucre bell-shaped or hemispheric, the bracts narrow, nearly equal, in 1 or 2 series, differing from Aster in which the bracts are in many series.—About 150 species scattered over the world, particularly in temperate and mountainous regions.

The garden fleabanes are practically all perennials. A few annuals are harmless and pretty weeds. Some species have roots that are biennial, but they increase by offsets, and make larger clumps from year to year. They are of easy culture. They do best when somewhat shaded from the mid-day sun. They are easily propagated by seeds or division, and doubtless by cuttings, if there were sufficient demand. Small, divided plants set out in early spring produce good-sized flowering plants the first year. A good show of bloom may be had from seeds sown outdoors as early as possible in spring. Some fine masses of these plants in the hardy border or wild garden are much more desirable than an isolated specimen or two of each kind. The most popular species is *E. speciosus*. At present it is the best kind that has the rich soft colors, from rose to violet and purple. *E. aurantiacus* has dazzling orange flowers, and is unique in the genus.

1415. *Erica melanthera*.

A. *Fls. orange.*

1. *aurantiacus*, Pegel. More or less velvety: height 9 in.: lvs. oval-oblong, clasping at the base, more or less twisted: heads 1 on a st.; involucre scales loose, reflexed. July, Aug. Turkestan. R.H. 1882:78. Gn. 52, p. 485. G. 5:239. J.H. III. 52:303.—Perhaps the showiest of the genus. Sold as "double-orange daisy."

AA. *Fls. creamy or white.*B. *Lvs. linear.*

2. *ochroleucus*, Nutt. Height 9–18 in.: sts. mostly not branched: lvs. rather rigid: rays 40–60, white or purplish, never yellow. Gravelly hills and plains N. Wyo. and Mont. to Utah.—This and the next are rare kinds in cult., sometimes sold by collectors and dealers in native plants.

BB. *Lvs. broader, lanceolate to ovate, or obovate.*

3. *Höwellii*, Gray. Height about 1 ft.: root-lvs. obovate; st.-lvs. ovate, half-clasping, all thin: rays 30–35, 1–2 lines wide, white. Mountain meadows, Cascade Mts., Ore. and Mont.

4. *mucronatus*, DC. (*Vittadinia triloba*, Hort., not DC.) Lvs. lanceolate, narrowed at base, ciliate, mostly entire, often with a long, callous mucro. Mex. This plant, grown in Calif., is a much-branched perennial with variable sometimes lobed lvs., and the white rays purple on the back. G.C. III. 48:203.

5. *Coulteri*, Porter. A slender equally leafy perennial about 15 in. high: lvs. thin, obovate or oblong, almost mucronate, and usually soft-hairy: fls. solitary on each stalk, sometimes 2 or 3 together, the white rays about 1 in. long. July. Rocky Mts. G.C. III. 30:99. Gn.W. 3, p. 587; 16:440.

AAA. *Fls. rosy violet or purple.*B. *Rays 100 or more, mostly narrow: lvs. entire.*c. *Fl.-heads large.*D. *Involucre hairy.*E. *Height about 2 ft.: sts. several-fl.*

6. *speciosus*, DC. (*Stenactis speciosa*, Lindl.). Height 1½–2 ft., the st. more or less woody: hairs few, loose: st. very leafy at top: root-lvs. more or less spatulate; st.-lvs. lanceolate, acute, half-clasping. Brit. Col. to Ore. near the coast. B.M. 3606. B.R. 1577. Gn. 52:484. G. 21:15. Var. *superbus*, Hort., sold abroad, has lighter colored and more numerous fls. Gn. 75, p. 118. G. 31:81. Var. *major*, Hort., has broader rays and brighter colors. Var. *roseus*, Hort. Ray-florets lilac; disk-florets yellow. Var. *grandiflorus*, Hort. Fls. larger and deeper in color than in var. *superbus*.

EE. *Height 9–15 in. or less: sts. usually 1-fl.*

7. *glabrus*, Ker-Gawl. BEACH ASTER. Lvs. slightly glaucous or often green in cult.; root-lvs. rarely 2–3-toothed: rays not narrow, light lavender-blue. Pacific coast, where it flowers most of the year. B.R. 10. Gn. 52, p. 484. Var. *semperflorens*, Hort. A dwarf floriferous form.

8. *alpinus*, Lam. (*E. Røylei*, Hort.?). A dwarf species suitable for rockwork: sts. hairy, bearing a single head of purplish fls.: lvs. acute, lanceolate, sometimes ciliate but otherwise entire. Northern regions. L.B.C. 6:590. —Suitable chiefly for alpine gardens.

DD. *Involucre not hairy.*

9. *macranthus*, Nutt. Height 10–20 in.: hairs numerous and long or short, sometimes nearly absent: lvs. lanceolate to ovate: rays very numerous, at least ¾ in. long. Rocky Mts., Wyo. to New Mex. and S. W. Utah. Gn. 52, p. 484. G.C. III. 46:53.—A good species. Blooms later than the eastern species. Violet. Hardy. Can be used with good effect in mass plantings of autumn-flowering asters and goldenrods.

cc. *Fl.-heads (or disk) small.*

10. *glabellus*, Nutt. (*E. asper*, Nutt.). Height 6–20 in., the st. simple or a little branched above: root-lvs. spatulate; st.-lvs. lanceolate, gradually narrowing into bracts: involucre bristly, or at least pubescent; rays violet-purple or white, very narrow. Minn. to Rockies. Gn. 52, p. 485. B.M. 2923. B.B. 3:385. L.B.C. 17:1631.—Much cult. abroad. Var. *arizonicus*, Hort. A variety from Ariz.

BB. *Rays 70 or less, wider: lvs. entire or toothed.*c. *Lvs. almost or quite entire.*D. *Sts. with several fls. in a corymb.*

11. *Villarsii*, Bell. Root biennial: height 1 ft.: lvs. with 3 or 5 nerves, roughish: fls. corymbose. Eu. B.R. 583. L.B.C. 14:1390.—Not cult., but in I.H. 43, p. 301, said to be a parent with *E. aurantiacus* of *E. hybridus roseus*, Hort., Haage & Schmidt. This is said to resemble *E. Villarsii* in habit, and *E. aurantiacus* in form of fls. but not in color. Said to bloom freely from May to autumn.

12. *philadelphicus*, Linn. Perennial by offsets: a roughish, much-branched herb with spatulate or obovate lvs. often st.-clasping along the upper part of the st.: heads several, corymbose, the numerous purplish white rays being attractive in June. N. Amer.—Almost a weed and easily grown in any ordinary garden.

DD. *Sts. mostly 1-fl.*

13. *salsuginosus*, Gray. Height 12–20 in.: upper st.-lvs. with a characteristic mucro: rays broad, giving an aster-like effect, purple or violet; the slightly viscid character of the involucre is particularly designative. Wet ground, on higher mountains, Alaska to Calif. and New Mex. C.L.A. 21. No. 11:40.

cc. *Lvs. coarsely toothed above the middle.*

14. *bellidifolius*, Muhl. (*E. pulchellus*, Michx.). POOR ROBIN'S PLANTAIN. Makes new rosettes by offsets from underground sts.: height 2 ft.: root-lvs. wider above the middle than in most species; st.-lvs. fewer: fls. spring, clear blue, on long sts. Damp borders of woods. Canada to Ill. and La. B.M. 2402. B.B. 3:388.—Weedy.

*E. caeruleus*, Hort.=(?).—*E. divergens*, Torr. & Gray. Diffusely branched with pubescent lvs. and white or purple fl.-heads. W. U. S.—*E. flagellaris*, Gray. A spreading plant bearing a profusion of white or pale lilac fl.-heads. W. U. S.—*E. grandifolius elatior*, Hort. "Large solitary fls. with purple disk. June and July."=(?).—*E. leiomerus*, Gray. Lvs. small, linear: solitary fl.-heads with violet rays and a yellow disk. Colo. B.M. 7743.—*E. multiradiatus*, Benth. & Hook f. Fl.-heads terminal, solitary: ray-florets purplish; disk yellow; height 6 in. to 2 ft. Himalayas. B.M. 6530.—*E. neomexicanus*, Gray. Fl.-heads loosely paniced; ray-florets linear, white; disk-florets tubular, yellow. New Mex.—*E. purpureum*, Hort., according to H. A. Dreer, "rarely exceeds 10 in. height, and has medium-sized fls. of soft, rosy purple, borne in graceful, spreading panicles." Form of *E. macranthus* (?).—*E. trifidus*, Schlecht. Fl.-heads white or pale lilac, daisy-like. Rocky Mts. *E. uniflorus*, Linn. Involucre hirsute, lanate, occasionally becoming naked; rays purple or sometimes white. Arctic regions.

WILHELM MILLER.

N. TAYLOR.†

ERINACEA (Latin, *erinaceus*, hedgehog, alluding to the spiny nature of the plant). *Leguminosae*. A low almost leafless shrub forming dense spiny tufts covered in spring with numerous blue flowers.

Deciduous, very spiny: lvs. simple or ternate, pubescent, only present at the end of young branchlets: fls. 1–3, axillary toward the end of the branchlets; calyx tubular, with 5 short teeth, inflated after flowering; petals narrow, long-clawed, claws of the wings and keel adnate to the staminal tube; standard ovate, slightly auriculate at the base; stamens connate: pod oblong, glandular-hairy, 2-valved, 4–6-seeded.—One species in S. W. Eu. Not hardy N.; likes limestone soil and a sunny position, best adapted to be planted in rockeries. Prop. by seeds.

*pungens*, Boiss. (*Anthyllis Erinacea*, Linn.). Shrub, to 1 ft.: lfts. 1–3, oblong-obovate or spatulate, ⅓–½ in.

long, pubescent: fls. 1-3, nearly 1 in. long, violet-blue, the petals exceeding the large inflated calyx only about one-third; the short pedicels, bractlets and calyx pubescent: pod about  $\frac{3}{4}$  in. long. May, June. Mountains of S. France, Spain and Corsica. L.B.C. 4:318. B.M. 676. G.C. III. 41:310. Gn. 62, p. 127; 64, p. 399.

ALFRED REHDER.

**ERINUS** (a name used by Dioscorides). *Scrophulariaceæ*. A hardy tufted plant 3 or 4 inches high, suited for steep sides of alpine gardens, where it produces in spring its racemes of small purple, rosy or white flowers.

One species, in the mountains of W. and Cent. Eu.: root-lvs. crowded, opposite; st.-lvs. alternate, oblong-spatulate, with a few coarse, rounded teeth: corollalobes 5, obovate, the 2 upper ones slightly smaller; stamens 4, in 2 groups, included; style very short, 2-lobed at apex: caps. ovate, obtuse, dehiscent.—Several species described in this genus belong in *Zaluzianskya*. Not to be confounded with *Lobelia Erinus*.

1416. Loquat. ( $\times \frac{3}{4}$ )

*Erinus* should be planted in steep parts of the rockery where water cannot lodge on rainy days or in the winter and spring months. It needs slight shade from mid-day sun. Divided plants are chiefly sold in America, but the amateur can soon produce a good carpet by the use of seeds. When well established, the seeds are self-sown and the offspring gain in hardness. It may be safest to keep a pot or two in a coldframe over winter, until the plant can take care of itself. In England, seeds may be sown in earthy holes of brick walls, and grown as informal masses on old stone steps. (J. B. Keller.)

**alpinus**, Linn. Racemes  $2\frac{1}{2}$  in. long; fls.  $\frac{1}{2}$  in. across, purple. April-June. B.M. 310. Vars. *albus* and *carminæus*, Hort., have white and crimson fls. respectively. Var. *hirsutus*, Gren. (*E. hirsutus*, Hort.). More vigorous: lvs. villous or hairy; violet-red.

WILHELM MILLER.

**ERIOBÔTRYA** (Greek, *woolly cluster*). *Rosaceæ*, subfamily *Pomeæ*. Small tree, grown for its handsome large foliage and also for its edible acid fruits.

Evergreen trees or shrubs: lvs. alternate, short-petioled or nearly sessile, dentate, with strong veins running straight to the teeth: fls. in terminal, broad panicles; calyx-lobes 5, acute; petals 5, oval or sub-orbicular, clawed; stamens 20; styles 2-5, connate below; ovary inferior, 2-5-celled; cells 2-ovuled: fr. a pome with persistent incurved calyx-teeth, thin endocarp and 1 or few large, ovoid or angular seeds.—About 10 species in the warmer regions of China, Japan, Himalaya and S. Asia. Closely related to *Photinia*, from which it differs chiefly in the larger fr. with thin endo-

carp and few large seeds and in the lvs. having straight veins ending in the teeth. The only species known in cult. is *E. japonica*, an evergreen tree with large ornamental foliage, comparatively inconspicuous white fragrant fls. in terminal rusty-wooly clusters, followed by large pear-shaped yellow frs. It can be cult. only in warmer temperate regions, and if protected during the winter, may be grown as far north as Philadelphia; does not seem to be exacting as to the soil. Prop. by seeds.

**japonica**, Lindl. (*Photinia japonica*, Gray). **LOQUAT**. Fig. 1416. Small tree, to 20 ft.: lvs. thick, evergreen, nearly sessile, oval-oblong or obovate, remotely toothed, bright green and lustrous above, rusty-tomentose below, 6-10 in. long; panicles 4-7 in. long; fls. white,  $\frac{1}{2}$  in. across, nearly hidden in the rusty-wooly pubescence: fr. pear-shaped, yellow, about  $1\frac{1}{2}$  in. long, with few large seeds, of agreeable acid flavor. Sept., Oct.; fr. April-June. Japan, China. B.R. 365. G.C. III. 26:660 (suppl.); 52:318. H.U. 3, p. 97. A.G. 1891, pp. 19, 370. G.W. 3, p. 439; 8, p. 314.—The loquat is native to China and Japan, but is much planted in the Gulf states and westward. It blooms from Aug. until the approach of winter, and ripens its clustered fr. in very early spring. The fr. is often seen in northern markets. It is a profuse bearer in congenial climates. See *Loquat*. Loquat is an excellent decorative plant, either as an evergreen lawn tree south of Charleston, or as a pot-plant in the N. It is a most satisfactory conservatory subject, resisting uncongenial conditions. Var. *variegata*, Hort. Lvs. variegated with irregular markings of pale green, dark green and white.

ALFRED REHDER.

**ERIOCÉPHALUS** (from *erion* wool, and *kephale*, head, in allusion to the wooliness of mature heads). *Compositæ*. A scarce little-known group of greenhouse shrubs, grown for their violet-white flowers and pleasantly scented leaves.

Leaves usually entire, sometimes 3-lobed, often in bunches: fls. in umbellate clusters in the only cult. species, in some others racemose; heads with white ray-fls. and purplish disk-fls.; involucre in 2 series, the outer series of 4-5 bracts.—Twenty species, all S. African, but only one seems to be grown and this is confined to fanciers' collections in Amer.

It is best grown in the temperate house in a mixture of sand and peat. Propagated by cuttings, in sand, under a bell-jar.

**africânus**, Linn. Lvs. opposite or tufted, silky-pubescent, about  $\frac{1}{2}$  in. long, thickish, channeled; heads umbellate at the ends of the branches, the white-rayed, purple-centered heads making attractive clusters. S. Afr. B.M. 833.

*E. pectinifolius*, Linn. An attractive yellow-fl. sort with smooth green lvs. is perhaps referable to *Hippia frutescens*. B.M. 1855. It is known only in botanic gardens in Amer.

N. TAYLOR.

**ERIOCÈREUS** (*woolly* and *Cereus*; referring to the wool in the axils of the bracts on the ovary). *Cactaceæ*. Usually slender plants, at first erect, but usually afterward clambering and creeping, often forming great clumps and thickets: fls. usually large; ovary covered with more or less enlarged bracts bearing hairs and spines in their axils: fr. red, spiny; flesh white; seeds numerous, black. For cult., see *Succulents*.

**Jusbértii**, Riccob. Ribs 6, usually low, with broad intervals; spines very short: fls. funneliform; petals white; stigma-lobes linear, green; bracts on ovary and fl.-tube filled with long hairs. It is now believed that this species is a hybrid between an *Echinopsis* and some *Cereus*.

See *Cereus* for descriptions of the following species: *Bonplândii*, Riccob; *Cavendishii*, Riccob. This is described under *Cereus*, but probably does not belong to either genus; *Martini*, Riccob; *platygônus*, Riccob; *tephracanthus*, Riccob; *tortuosus*, Riccob.

J. N. ROSE.

**ERIOCHILUS** (*woolly lip*). *Orchidaceæ*. A half-dozen species of terrestrial orchids from Austral., with small subterranean tubers and a solitary lf. at the base of the st. or higher up: fls. pink or white, 1 or more and sessile on a scape or peduncle; labellum much shorter than lateral sepals, the margins often with small and erect lateral lobes. Some of the species have been mentioned as greenhouse subjects, but they are horticulturally little known.

**ERIOCNEA**: *Bertolonia*.

**ERIODENDRON**: *Ceiba*.

**ERIODICTYON** (*woolly net*, referring to the under surface of the lvs.). *Hydrophyllaceæ*. Four species and many varieties (see Brand in Engler's *Pflanzenreich*, hft. 59, 1913) of shrubs of Calif. and the Great Basin, with alternate coriaceous entire lvs., and white, purple or blue fls. in scirpioid cymes. Apparently not cult. *E. Parryi*, Greene = *Nama*.

**ERIOGONUM** (Greek, *woolly joints*). *Polygonaceæ*. About 140 species, W. N. American (with extension into Mex.), herbs tufted sub-shrubs or slender annuals, mostly densely woolly: lvs. crowded at the base of the st., alternate or whorled, entire: fls. small, perfect, in an involucre head, fascicle or umbel, mostly recurved or reflexed with age, mostly white, rose or yellow; perianth 6-parted; stamens 9; styles 3: fr. an achene, mostly 3-angled. Now and then some of the species are listed by dealers in native plants, but they can hardly be regarded as cult. subjects. *E. compósitum*, Douglas, perhaps the best known, has very many minute neutral-colored fls., dull white to rosy, borne in compound umbels 5-6 in. deep and broad. B.R. 1774. The following have been advertised, but are practically unknown in our gardens: *E. campanulatum*, *E. compósitum*, *E. flavum*, *E. heracleoides*, *E. incanum*, *E. microthécum* var. *effusum*, *E. niveum*, *E. nudum*, *E. ovalifolium*, *E. racemósum*, *E. sphærocéphalum*, *E. thymoides*, *E. umbellatum*. *E. giganteum* makes a mound or mat many feet across. G.C. III. 28:337. Descriptions of eriogonums may be readily found in the floras of the western part of the U. S.

**ERIOGYNIA**: *Luetkea*.

**ERIOLOBUS**: *Pyrus*.

**ERIOPHORUM** (*wool-bearing*, from the Greek; alluding to the heads of fr.). *Cyperaceæ*. Perennial rush-like plants, growing in swales: fls. in dense heads, the perianth-bristles very numerous and often becoming greatly elongated in fr. and giving the head a wool-like appearance. None of them is known in cult., but the following names have been offered by collectors for bog gardens: *E. alpinus*, Linn.; *E. cyperinum*, Linn.; *E. lineatum*, Benth. & Hook.; *E. polystachion*, Linn.; *E. vaginatum*, Linn.; *E. virginicum*, Linn. All these are wild in the northern states, and descriptions may be found in the regular manuals. *Eriophorum* comprises upward of a dozen species in the northern hemisphere.

**ERIOPHYLLUM** (Greek, *woolly-leaved*). *Compositæ*. Herbs, mostly woody, and commonly with yellow-rayed heads; one kind cult. in a few hardy borders is a low, tufted, herbaceous perennial, with much-divided lvs., covered with wool beneath (each st. bearing about 5), and 8-rayed yellow heads 2 in. across, borne in a loosely forking fashion on peduncles 3-7 in. long. The genus was included in *Bahia* by Benth. & Hooker, but is now kept distinct largely because of the permanently erect involucre bracts: seeds mostly 4-angled, and pappus of nerveless and mostly pointless, colorless portions. *Actinolepis* is included in this genus by some authors. There are about a dozen species, in N. W. Amer. *E. cæspitòsum*, Douglas (*Actinella lanata*, Pursh, not Nutt. *Bahia lanata*, DC.), described

above, has been advertised. Either moist or dry ground, Mont. to Brit. Col. and S. Calif.; very variable.

**ERIOPSIS** (Greek, *like Eria*, an orchid of the *Epidendrum* tribe, which it resembles when not in flower). *Orchidaceæ*. Five or six South American orchids of the *Vanda* tribe allied to *Acacallis* and *Warrea*, requiring coolhouse treatment as given to *Cattleya*; epiphytes. Leaves 2 or 3, long, plicate: racemes 2 or 3, basal; fls. open, small, but showy, maxillaria-like; lip 3-lobed, the lateral lobes broad and erect and inclosing the column, the middle lobe small and spreading and sometimes 2-lobed.—About half a dozen species in S. Amer.

**biloba**, Lindl. Pseudobulbs 3 in. long: lvs. lanceolate: fls. 1 in. across; sepals and petals yellow, with orange-red margins; labellum yellow spotted with brown. Colombia. B.R. 33:18.

**rutidobúlbon**, Hook. Stoutier in habit than the above: pseudobulbs wrinkled, dark-colored: racemes drooping; sepals and petals orange-yellow, with deeper colored margins; labellum white, with purple spots. Antioquia, in exposed positions on the sts. of palms. Peru. B.M. 4437.

**Hélenæ**, Kränz. Said to be the finest in the genus. It differs greatly in habit from the other members; the pseudobulbs (standing 16 in. high) somewhat resemble those of *Epidendrum Brassavolæ*, but are much stronger, and bear 3 long, coriaceous dark glossy green linear-lanceolate lvs. The fls. are twice as large as those of *E. biloba*, and are borne on tall, arching scapes. The sepals and petals are orange-colored, margined with purple, the lip similar, but with a yellow blotch, spotted with purple at the base. Peru.

*E. Fuerstenbergii*, Kränz. Racemes up to 12 in. long; fls. about 1½ in. across; sepals and petals brown outside, orange with brown border inside; lip whitish, densely dotted with purple.

OAKES AMES.

**ERIOSTEMON** (Greek, *woolly stamens*). *Rutaceæ*. Coolhouse evergreen shrubs from Australia, with starry, five-petaled flowers an inch wide, of white or blush-pink. Very little known in America, but abroad considered amongst the finest of hard-wooded winter or spring-blooming Australian plants.

Leaves alternate, entire, glandular-dotted: infl. axillary or terminal, solitary or in clusters; calyx and corolla 5-parted, rarely 4-parted; stamens 8-10, free, shorter than the petals; anthers pointed: fr. 2-valved, 1-seeded. Much care is needed to produce well-trained specimens.

Eriostemons are among the most beautiful of Australian hard-wooded plants. They are propagated from cuttings made of the points of half-ripened wood. Choose pieces about 3 inches long, and insert in a pot filled with one part finely sifted peat, and two parts sharp sand. Water them and set in a case in a temperature of 55° to 60°, shading them from the sun. After they have rooted, pinch out the heart of the shoots, and when they show signs of breaking, transfer them singly into small pots in equal parts of peat and sand. When well rooted in these pots, give them a shift about two sizes larger, using good fibrous peat, in rather a lumpy state, and about a fifth part of good sharp sand, adding a little of finely broken charcoal. This compost may be used for all future pottings. If large plants are wanted quickly, it is better to grow them indoors all the year round, but they will not set flowers so well. Eriostemons flower in the smallest sized pot in spring, if they are grown outdoors all summer. The outdoor treatment ripens the wood thoroughly and the result will be seen when flowering time arrives. These plants are liable to run into strong shoots to the detriment of the weaker ones. When this is observed, cut them well back, and this will preserve the symmetry of the plant. During their growing period they should be syringed freely. This helps to soften the wood and secure

plenty of breaks, and also keep red-spider in check. A favorite method of propagation in the British Isles is by grafting on small plants of *Correa alba*. This insures a quicker means of raising the plants and is practised largely by nurserymen. A winter temperature of 40° by night should be maintained. However, if plants are wanted to flower earlier, they may be subjected to 50° or 55°. Eriostemons are sometimes attacked by brown and white scale. Fumigation with hydrocyanic gas is the best remedy. (George F. Stewart.)

A. *Foliage linear or narrowly lanceolate.*

B. *Lvs. linear.*

**scâber**, Paxt. A shrub with minutely pubescent or glabrous branches: lvs. covered with minute roughnesses, sessile, acute and mucronulate: petals white, tipped pink. P.M. 13:127.

BB. *Lvs. narrowly lanceolate.*

**linifolius**, Seghers. Lvs. broadest at middle, tapering both ways. R.B. 20:97.—Probably an old garden form of some well-known species.

**affinis**, Sprague. Shrub, 1–2 ft., the branches glabrous and shining: lvs. sessile, linear-lanceolate, 1–2 in. long, glabrous: fls. in axillary slender clusters, quite like the next, but smaller.

AA. *Foliage conspicuously wider.*

B. *Lvs. 10–12 times as long as broad.*

c. *Apex abruptly pointed.*

**myoporoides**, DC. Lvs. widest at the middle, tapering evenly both ways, 1–3, rarely 4 in. long: fls. umbellate; petals white or sometimes pink, glandular on the back. B.M. 3180.

cc. *Apex blunt.*

**salicifolius**, Smith. This willow-leaved species has perhaps the handsomest foliage. Lvs. widest above the middle, tapering more gradually to the base than to the apex: petals bright, soft pink. B.M. 2854.

BB. *Lvs. 3–4 times as long as broad.*

**intermedius**, Hook. Lvs. 9–18 lines long, elliptical, abruptly pointed: petals lanceolate, white, but tipped with pink outside in the bud like the rest; ovary placed on a flat disk and not ringed at the base. Probably of garden origin. Intermediate between *E. myoporoides* and *E. buxifolius*. B.M. 4439.

**buxifolius**, Smith. Lvs. as in *E. intermedius*, though perhaps smaller: petals obovate, white, tipped pink; ovary sunk into a double disk of 2 rings. B.M. 4101. G. 26:19.—*E. densiflorus*, Seghers, R.B. 20:97, looks like a prolific horticultural variety of this species.

WILHELM MILLER.

N. TAYLOR.†

**ERITRICHUM**: For *E. barbigerum*, see *Krynitzkia*. For *E. nothofulvum*, see *Plagiobothrys*.

**ERLANGEA** (bears the name of the University of Erlangen). *Compositæ*. One species of this genus, blooming in midwinter and spring, is offered in England.

The genus was long considered to be monotypic, but Moore has recently (Jour. Bot. 46. 1908) incorporated *Bothriocline* with it, and the new species have expanded the genus to 32 species, all Trop. African excepting 1 in New Guinea; it differs from *Vernonia* "only in the curious reduced achenes and the pappus of few, short, very caducous setæ." *E. tomentosa*, Moore (*Bothriocline Schimperii* var. *tomentosa*, Oliv. & Hiern). Shrub, to 5 ft.: st. and under sides of lvs. tomentose: erect herb: lvs. opposite or at top of st. rarely alternate, oblong to ovate-lanceolate, 2–5 in. long, nearly or quite obtuse, rounded at base, serrate, villous: fls. all tubular, about 40 in the head, the heads about ½ in. diam., short-peduncled and collected in

corymbose panicles; involucre-scales ovate, acute, scarious-margined. Trop. Afr. B.M. 8269. Foliage scented: fls. mauve or lilac, lasting 2 or 3 months in winter; habit of a eupatorium, and requires the treatment given the greenhouse members of that genus.

L. H. B.

**ERODIUM** (Greek, *a heron*; alluding to the beaked fruit). *Geraniaceæ*. **HERON'S-BILL** or **STORK'S-BILL**. Annual and perennial, some of the perennials grown in flower-gardens and with alpenes for their finely cut foliage and mostly purplish or white flowers.

The plants suggest the wild and hardy geraniums, from which they differ in having only 5 instead of 10 anther-bearing stamens, the other 5 being reduced to scales; also the tails of the carpels hairy inside and twisting spirally. Herbs, rarely somewhat woody or tufted: lvs. opposite or alternate, one often smaller than its mate, stipuled, toothed, lobed, or dissected: fls. regular or nearly so, mostly in umbels, of various shades, from crimson-pink to purple, with darker blotches on the 2 upper petals and the venation outlined in darker shades; sepals 5, imbricate; ovary 5-lobed, when ripe splitting into separate caps-lobes, each lobe 1-seeded: plants usually heavy-scented.—The latest monograph (Knuth, in Engler's *Pflanzenreich*, lft. 53, 1912) describes 60 species, widely dispersed in temperate and warm regions. The self-planting of the seeds or carpels of some species is very interesting.

These plants are chiefly for the front row of the hardy borders and the rock-garden, where they thrive in a gritty loam. They like dry, sunny spots, and may be trusted with a conspicuous position, being chiefly valued for their steady succession of bloom from June to August. Divided plants are chiefly sold here, but the species are easily propagated by seeds. Some erodiums can be grown in chinks of walls. Some of the annual kinds are widely spread in California and other parts of the West, and *E. cicutarium* and two or three others are grown for forage. The garden species have not attained much prominence in this country.

#### A. Plant annual (or biennial).

1. **cicutarium**, L'Her. **ALFILARIA**. **ALFILERILLA**. **PIN-CLOVER**. Tufted, low and spreading, more or less glandular, often with coarse, soft, short hairs: lvs. oblong, 1–2-pinnate; lfts. small, nearly sessile, the uppermost confluent, lower ones sharply and deeply cut and with narrower lobes: stipules small, acute: sepals with 1 or 2 terminal bristles; filaments not toothed; fls. rose-purple. Abundantly run wild from the Rocky Mts. to the Pacific, on dry or barren lands, and also grown for hay and utilized as wild pasture. Feb.–Apr. Old World; immensely variable.

2. **moschatum**, L'Her. **FILAREE**. **MUSK-CLOVER**. Also **ALFILERILLA**. Glandular and musk-scented, at first stemless and with a rosette on the ground but later sending up stout fleshy sts. to 1 ft.: lfts. large, short-stalked, ovate to elliptical, serrate, broad-lobed: stipules large, rather obtuse: sepals not terminated by bristles; filaments 2-toothed; fls. rose-purple. Medit., Orient. Run wild in Calif. in the rich valley lands.

3. **Bötrys**, Bertol. Branching from the base and usually prostrate, white-pubescent: lf.-blades 1–2 in. long on petioles of similar or twice the length, oblong-ovate, pinnatifid, the lobes acute and serrate: sepals with 1 or 2 short bristles; fls. deep violet; filaments

widened upward and toothed. *Medit. region, now widely spread in Calif. and also grown for forage.*

AA. *Plant perennial.*

B. *Fls. yellow.*

4. *chrysanthum*, L'Her. Woody, 1-5 in. tall, silvery, the rhizome vertical: lvs. densely crowded at base, petiole and blade of equal length, broadly ovate, obtuse or nearly so, pinnate, the pinnæ cut; st.-lvs. few or none, subsessile: peduncles sometimes basal; fls. yellow, the petals exceeding sepals, broadly cuneate and retuse. *Greece. Gt. 1, p. 260.*

BB. *Fls. white, sometimes veined or spotted.*

5. *guttatum*, Willd. Woody, 3-6 in., the caudex vertical: lvs. many at base of st., long-petioled, ovate-cordate or long-cordate, obscurely lobed, crenulate: peduncle 2-5 in. high; fls. clear white with a dark spot at base of upper petals; sepals lance-spatulate or obovate-spatulate; petals broadly obovate, rounded. *S. W. Medit. region; a good little rock plant. Gt. 3, p. 244.*

6. *pelargoniflorum*, Boiss. & Heldr. Woody, to 1 ft. or more, the caudex vertical: basal lvs. rather numerous, long-petioled, hairy above, ovate-cordate, somewhat lobed, obtusely crenate-dentate: peduncles 1-5 in. high; fls. white, the 2 upper petals spotted with pink at base; sepals ovate; petals broadly obovate, rounded or retuse. *Asia Minor. B.M. 5206. Gt. 1:194. Gn. 59, p. 448; 63, p. 107.*

7. *supracanum*, L'Her. Stemless, 1-4 in. tall, the rhizome vertical: lvs. numerous, to about 2 in. long, densely silky-canescens above, green beneath, ovate or oblong, bipinnatisect, the pinnules entire or dentate or incised: fls. white, spotless, red-veined, the petals obovate and rounded, and sepals broadly ovate and 5-nerved. *Pyrenees.*

8. *chamædryoides*, L'Her. (*E. Reichardii*, DC.). Stemless, 2-3 in. tall: lvs. numerous, long-stalked, sparsely hairy, round-ovate, slightly cordate, crenate, apex rounded: peduncles about 1-fld., about 2 in. tall; fls. white, rose-veined; sepals ovate-spatulate or lance-spatulate, minutely mucronate; petals obovate, retuse. *Balearic Isls., Corsica.—An attractive alpine.*

BBB. *Fls. rose, red or purple (sometimes white in No. 14).*

C. *Lvs. undivided or obscurely lobed.*

9. *corsicum*, Lem. St. 2-6 in. high, the root vertical or oblique: basal lvs. many, long-petioled, grayish tomentose or becoming glabrous, ovate or broader, more or less obsoletely lobed, coarsely crenate-dentate: peduncle 1-2 in. high, about 2-fld.; fls.  $\frac{3}{4}$  in. across, in shades of rosy pink veined deeper color; sepals oblong-spatulate or ovate, not mucronate; petals broadly obovate or cuneate. *Corsica and Sardinia. G.C. III. 48:210.*

CC. *Lvs. all pinnatisect.*

D. *St. wanting.*

10. *macradenum*, L'Her. (*E. graveolens*, Lapeyr. *E. glandulosum*, Willd.). Remarkable for the great length of the roots when twisting among rocks, and strong odor of the foliage: 2-6 in.: lvs. hairy, glandular,  $1\frac{1}{2}$ -2 in. long, oblong, pinnate; segms. pinnatifid, rachis with a toothed wing: fls. light purple, the 2 upper petals a shade darker, and the spots nearly black. *Pyrenees. B.M. 5665.*

11. *daucoides*, Boiss. Plant 2-4 in., the rhizome vertical: lvs. many, tomentose, petiole exceeding blade, lanceolate or triangular in outline, the pinnæ pinnatisect and the lobes linear-lanceolate: peduncles standing above the foliage, about 4-fld.; fls. rose-color; sepals more or less ovate, 5-nerved; petals obovate, somewhat rounded. *Spain.*

12. *Manescavi*, Coss. Height 10-18 in., the rhizome vertical or oblique: lvs. attaining 6 and more in. long,

$2\frac{1}{2}$  in. wide, lanceolate or ovate-lanceolate; segms. alternate ovate, short-stalked, dentate, with sometimes a deeper cut: fls. at best 2 in. across, strong rosy purple, the spots of the upper petals only a shade or two darker. *Pyrenees. Gn. 55:292.—Colors stronger and more uniform than No. 10.*

DD. *St. evident.*

13. *Guicciardii*, Heldr. Woody, to 8 in. tall, from a more or less vertical rhizome: basal lvs. many, densely clustered, petiole equaling the blade (upper st.-lvs. sessile), silvery, broadly ovate or oblong-ovate, pinnate; pinnæ cut into linear or oblong-linear lobes: peduncle 1-3 in. tall, 4-7-fld.; fls. rose-colored; sepals ovate, obtuse and mucronate; petals obovate, rounded. *N. Greece.*

14. *absinthioides*, Willd. (*E. petræum*, Sibth. & Smith. *E. olympicum*, Clem. *E. Sibthorpiænum*, Kotschy). Two to 8 in. tall: rhizome vertical: lvs. many, crowded at base of st., the petioles very short (st.-lvs. few and sessile), soft-hairy, oblong or triangular-ovate, obtuse or acutish, bipinnatisect; lobes linear-lanceolate, entire or dentate: peduncle 1-4 in., 2-8-fld.; fls. violet or rose (rarely white), the sepals ovate, obtuse and mucronate, the petals cuneate-obovate. *Asia Minor.*

*E. gruinum*, L'Her. Annual or biennial,  $1\frac{1}{2}$  ft. high, the sts. 1 or few, white-hairy: lvs. cordate-ovate, undivided or obscurely lobed, dentate: fls. violet-blue, large, the petals broadly obovate and clawed, rounded at apex. *Sicily to Persia, N. Afr.—E. Stephaniænum*, Willd. Annual or biennial, villous, branched: lvs. nearly glabrous, bipinnatifid, the lobes linear; peduncles 2-3 in. high, 2-5-fld.; fls. dark purple; petals scarcely surpassing sepals, very broad-ovate. *Temp. Asia.*

L. H. B.†

ERPETION: *Viola.*

ERÛCA (origin of name in doubt; probably from the Latin *to burn*, in allusion to the hot seeds). *Cruciferae*. Perhaps ten or a dozen herbs of Eu. and W. Asia, annual or biennial. Allied to Brassica: differs in the shorter, more turgid silique, with keeled valves; style elongated; seeds in 2 rows in each cell. The lvs. are pinnately lobed or dentate, and the fls. rather large, yellow to purplish. *E. sativa*, Mill., ROQUETTE, TIRA or ROCKET-SALAD, is the only species cult. in this country. It is a weedy annual, resembling a mustard, 1-2 ft. high, with lyrate-pinnatifid lvs. and creamy yellow or whitish fls. in a raceme (which elongates in fr.). It is sparingly run wild in Canada, U. S., and Mex. See *Roquette*.

L. H. B.

ERYNGIUM (a Greek name for some sort of thistle). *Umbelliferae*. ERYNGO. SEA-HOLLY. Annual and perennial herbs, chiefly valued for the steel-blue or purplish cast of their rigid stems, prickly foliage and teasel-like heads.

Rarely shrubby: lvs. stiff or coriaceous, undivided, lobed or pinnatisect, the margin nearly always spiny: fls. small, white, greenish or blue, sessile or subsessile, bracteolate, in involucrate heads or spikes; calyx-teeth prominent, mostly rigid, sometimes ending in a spine-point; petals erect; disk expanded; styles slender: fr. ovoid or obovoid or more or less globose, scaly or tuberculate, without ribs, the carpels nearly terete and with usually 5 oil-tubes.—Wolff estimates (in Engler's *Pflanzenreich*, hft. 61, 1913) 220 species, widely dispersed in warm and temperate regions with the greatest extension in the *Medit. region*.

There are two very distinct groups of eryngoes, one with much-cut foliage, as shown in Fig. 1417, the other the "pandanus group" (of the New World), with long undivided leaves. The species are little grown in this country, but they are more used abroad. They produce striking semi-formal and often somewhat bizarre effects. They are used in subtropical bedding, particularly the large pandanus-leaved kinds. They are excellent for borders and rock-gardens, being prized particularly for their colored stems and often brilliant in-

volucere. The stiff leaves of the pandanus group are little damaged by weather. The dried stems retain their color, and are sometimes hung in living-rooms. The plants mostly grow from 2 to 3 feet high and head out in July to September. A light rich soil and sunny situation are advised. Poor drainage is to be avoided. *E. amethystinum* is probably the most popular species in this country. *E. planum* is said to be much visited by bees. They are slow to recover from the shock of division. This makes it difficult to work up a stock at home sufficient to make an effective group. The only safe way to increase them is by seed. The seed may be sown as soon as gathered. They will germinate in the spring, and should be ready to plant out the following year. Some of the species self-sow. The species described below are perennial.

## A. The pandanus-leaved group.

## B. Bracts of involucre long and prominent.

1. *agavifolium*, Griseb. Becoming 6 ft. high in its native country: st. simple below and somewhat branched above, 3-forked at top: basal lvs. rosulate, ensiform, to 5 ft. long, coarsely spinose-serrate: head cylindrical, about 2 in. long and half as thick; the involucre bracts 10-16, ovate at base and gradually narrowed, entire or sparsely spinulose; sepals round-ovate or nearly orbicular; petals obovate or elliptic-oblong. Argentina, blooming Jan.-March. G.W. 15, p. 477.

2. *bromeliæfolium*, Delar. Becoming 9 or 10 ft. tall, the st. about 4-forked at top: basal lvs. numerous, 1½ ft. and more long, narrow and very acute, the margins subulate-dentate, spine-pointed: head ovoid or ovoid-cylindrical, about 1 in. long; involucre bracts many, rigid, unequal, linear-subulate, pungent-pointed; sepals ovate-lanceolate, short-acuminate and mucronate. Highlands, Mex.; Dec.

3. *protæflorum*, Delar. Plant very stout, 3 ft. and more, the st. fistulose and sulcate: st.-lvs. very stiff, the upper ones 8 in. or more long, linear-lanceolate, long-acuminate and pungent-pointed, the margin subulate-spinose: head ovoid-cylindrical, 2½ in. long; bracts of involucre very many and very rigid, in several series, lanceolate and sharp-pointed; fls. very many; sepals broad-ovate, obtuse, short-mucronate; petals white, obovate-spatulate. Mex. Sept. G.C. III. 41:248, 249. Gn. 75, p. 380.

## BB. Bracts of involucre scarcely prominent, not very stiff.

## c. Nerves of lf. diverging.

4. *aquaticum*, Linn. (*E. yuccæfolium*, Michx.). BURTON SNAKE-ROOT. RATTLESNAKE MASTER. Height

2-6 ft.: st. striate, unbranched or branched above: lvs. undivided, long and linear, rigid, mostly clasping, finely parallel-veined, lower sometimes 3 ft. long, 1½ in. wide, all bristly margined: heads globose-ovoid. Wet soil, E. U. S.

## cc. Nerves of lf. parallel, prominent.

5. *Lassauxii*, Decne. Height 3-6 ft., the st. fistulose, 3-forked at top: basal lvs. often slightly twisted, canaliculate, to 2 in. wide, long-acuminate, the margin spiny: heads in a broad corymb, each one small, about ½ in. through, whitish green; involucre-bracts ovate-lanceolate, spinulose-ciliate; sepals nearly orbicular or 4-angled-orbicular, truncate and erose; petals rectangular-ovate. S. Brazil, Paraguay, Uruguay. G.W. 3, p. 549.

6. *pandanifolium*, Cham. & Schlecht. St. to 8 ft. high, leafy, 3-4-forked above: basal lvs. 4-5 ft. long, spine margined above; st.-lvs. many, to 1½ ft. long, spiny: heads colored, globose-ovoid, less than ½ in. long, in large panicles; involucre bracts broad-ovate, very acute, rough on the back; sepals nearly orbicular or oval, short-mucronate; petals dark purple, ovate or orbicular-oblong. S. Brazil, Argentina. Gn. 61, p. 37. G.W. 4, p. 197.

7. *eburneum*, Decne. (*E. bracteodsum*, Griseb.). Height 8 ft., from a thick rhizome, the st. ivory-white: basal lvs. crowded, canaliculate, 3 ft. and more long, acuminate, very spiny, the spines being slender: heads not colored, ovoid or globose-ovoid, ¾ in. long; involucre bracts triangular or lanceolate or linear; sepals ovate or oval, obtuse or short-acuminate; petals somewhat rectangular-oblong, fimbriate at apex. S. Brazil, Uruguay, Argentina.

## AA. The cut-lvd. group (or lvs., at least on st., broader, more or less toothed, and not pandanus-like).

## B. Lvs. fleshy.

8. *maritimum*, Linn. Glauco-blue, stiff, much-branched, about 1 ft. high: lvs. very stiff, broad, sinuate, more or less 3-lobed, handsomely veined, with coarse prickly teeth, those on the st. clasping, the radical ones petioled: heads nearly globular, pale blue; involucre bracts 5-8, much smaller and narrower than the st.-lvs.; sepals ovate-lanceolate; petals oblong. Seacoasts of Eu. Gn. W. 15:489.

## BB. Lvs. not fleshy.

## c. Basal lvs. usually not lobed (or not prominently so).

9. *alpinum*, Linn. Height 12 ft., bluish above, from a thick root: radical lvs. deeply cordate-triangular, acuminate, coarsely double-crenate; st.-lvs. round-cordate, often 3-lobed at the apex or palmatifid: head globose-cylindrical, about 1 in. long; involucre bracts 12-18, lance-oblong, rigid, multifid; fls. many; sepals ovate-lanceolate; petals somewhat rectangular. Eu. B.M. 922. G.C. III. 53:139. G.M. 46:136. Gn.W. 21:278. G.W. 3:576; 15, p. 478. R.H. 1876, p. 113. Gn. 46:523.—There is a white variety. Prized for the attractive blue color of the heads and upper part of the plant.

10. *Oliverianum*, Delar. (*E. alpinum* var. *Oliverianum*, Spreng.). Hybrid, perhaps of *E. planum* and *E. giganteum*, or perhaps with *E. alpinum*: plant strong

1417. *Eryngium amethystinum*. (×½)

3 ft.: lower lvs. long-petioled, broadly cordate-ovate, indistinctly 3-lobed at the apex, unequally spinulose-serrate; younger and the lower cauline lvs. 3-lobed or -parted and the lobes again more or less lobed or angled and the margins spinose-serrate; head blue, cylindrical-ovoid, or ovate, many-fl'd.; involucrel bracts 10-15, subulate or linear, somewhat spinulose. Gn. 45, p. 223; 60, p. 425. Gn. W. 20:791. G.W. 15, p. 497.

11. *tripartitum*, Desf. Probably a hybrid: radical lvs. unequally spinulose-serrate with a large obtuse middle lobe; st.-lvs. deeply 3-parted, the lobes lanceolate and rigid, spiny-toothed: head globular, small; involucrel bracts 6-9, narrow-lanceolate, spiny margined.

12. *gigantæum*, Bieb. (*E. asperifolium*, Delar. *E. glaucum*, Hoffm.). Stout, 6 ft., the root thick and turnip-shaped, the st. simple below and 4-5-forked above: lvs. coriaceous, the basal ones broadly cordate or cordate-triangular, toothed; st.-lvs. more or less 3-lobed, spinulose-dentate: heads cylindrical or ovoid-cylindrical, 3-4 in. long, in an ample infl., blue or pale green; involucrel bracts lanceolate to obovate, very rigid, much cut; fls. very many; sepals ovate or ovate-lanceolate; petals obovate-lanceolate. Caucasus, Asia Minor. Gn. 46, p. 523; 70, p. 111. G. 34:95. R.H. 1906, p. 379. G.W. 15, p. 479.

13. *plânium*, Linn. (*E. planifolium*, Pall. *E. latifolium*, Gilib. *E. intermedium*, Weinm.). Root thick turnip-shaped, very long: st. 3 ft., mostly single, 3-5-forked at top: basal lvs. cordate, oblong or oval or broadly obovate, obtuse, spinulose, usually palmately 7-9-nerved; lower st.-lvs. short-petioled, shaped like the basal lvs. or 3-lobed, the lobes deeply serrate or cut, the upper ones sessile and 3-5-parted: heads blue, ovoid or nearly globular, about  $\frac{1}{2}$  in. long; involucrel bracts mostly linear, rigid, somewhat spinulose-serrate; sepals lanceolate; petals ovate-oblong. Eu., Asia. G.L. 18:136.—A var. *roseum* is offered.

14. *dichotomum*, Desf. (*E. tricuspidatum*, Tenore). Two ft. or less, glaucous-blue, the st. strong, few-lvd., branchy, 3-5-forked at top: lower lvs. long-petioled, cordate-oblong or obovate, very obtuse, serrate or crenate, reticulated; upper lvs. rigid, 5-parted: head nearly globose or ovoid-globose, about  $\frac{1}{2}$  in. long; involucrel bracts 6-7, rigid, narrow-linear or subulate, somewhat spinulose, pungent-pointed; sepals ovate or ovate-lanceolate, spine-tipped; petals ovate-oblong. Medit. region.

15. *cœruleum*, Bieb. About 3 ft., blue, the root thick and long turnip-shaped, the st. usually solitary, 4-5-forked above, the branches long: basal lvs. all long-petioled, cordate, cordate-ovate or cordate-oblong, crenate-serrate, outer ones undivided, inner ones 3-lobed: heads small; involucrel bracts 4-6, rigid and wide-spreading, linear-lanceolate, spinulose; sepals narrow-lanceolate; petals oblong. Caucasus and E.

16. *Leavenworthii*, Torr. & Gray. Purple-violet above, 3 ft., the st. strict and full-lvd., at the top 3-forked: basal lvs. oblanceolate and mostly obtuse, spinose-dentate, the others deeply palmate-parted, the divisions cut-pinnatifid and the segms. spreading and pungent-pointed: heads ovoid-cylindrical, 2 in. or less long; involucrel bracts 7-9, linear-lanceolate, spinose-pinnatifid; sepals pinnatifid. Dry soil, Kans. to Texas.

cc. Basal lvs. on the flowering plant all lobed or divided.

17. *sérbicum*, Panc. Height 1-1 $\frac{1}{2}$  ft., blue above: root elongated, thick, somewhat woody: st. slender, sparsely lvd., short-branching and 3-4-forked above: basal lvs. long-petioled, fresh green, divided into 5-7 grass-like segms.; st.-lvs. more or less clasping or short-petioled, the segms. very narrow and remotely spinu-

lose-cut: heads small, globose-ovoid; involucrel bracts 5-7, rigid, narrow-linear, sharp-pointed; sepals broad-ovate, obtuse; petals broadly oblong-ovate. Servia.

18. *Spinálba*, Vill. Plant rigid, whitish green, more or less blue above: st. stout, at the top 3-4-forked: lvs. coriaceous, rigid, broadly cordate-ovate, palmately 4-5-parted, the margins undulate and spiny-toothed: head blue, ovoid-cylindrical; involucrel bracts about 10 and very rigid, deeply pinnatifid, spine-pointed; sepals lanceolate or more or less ovate; petals oblong-linear. Eu., in the Alps.

19. *Bourgatii*, Gouan (*E. Tournefortii*, Bub.). Low, usually about 1 $\frac{1}{2}$  ft.: root thick, somewhat turnip-form: st. mostly solitary, simple below, sparingly branched above, apex 3-forked: lvs. somewhat coriaceous, pale green, rigid, nearly orbicular or somewhat reniform, palmately 3-5-parted and again lobed, spiny-toothed; st.-lvs. palmate, somewhat clasping: heads blue or rarely green, nearly globose or ovoid-globose; involucrel bracts 9-15, spiny or not; sepals lanceolate, acute; petals spatulate. Medit. region.

20. *Zabélîi*, Hort. (*E. alpinum*  $\times$  *E. Bourgatii*). Plant rather robust, 1 $\frac{1}{2}$  ft.: basal lvs. suborbicular, 3-parted; the segms. cuneate at base and deeply 3-lobed and again 3-lobed, margins strongly spinulose-serrate: head globose-cylindrical, 1 in. or more long; involucrel bracts, 12-14, rigid, lanceolate, spinulose-dentate, blue or amethystine. G.W. 15, p. 496.

21. *améthystinum*, Linn. (*E. pallescens*, Mill.). Fig. 1417. Stout, 1 $\frac{1}{2}$  ft. and more, blue or amethystine above or sometimes whitish: root thick, long-cylindrical: st. remotely leafy, branched, 4-5-forked at top: lvs. rigid, obovate or oblong-ovate, bipinnatifid, spinose-dentate; upper st.-lvs. clasping, pinnately parted, spinulose-dentate: heads ovoid-globose,  $\frac{1}{2}$  in. or more long, the peduncle thick and sulcate; involucrel bracts 6-9, unequal, linear-subulate or lanceolate, sharp-pointed; sepals ovate-lanceolate; petals ovate-oblong or nearly rectangular. Eu. Gn. 46, p. 522; 55, p. 454. G.L. 23:199. Variable. Var. *multifidum*, Wolff (*E. multifidum*, Smith) has much-cut lvs.

Any number of eryngiums may be expected to appear in the list, as they are likely to strike the attention of collectors. They appear to hybridize rather freely. *E. hybridum* is a trade name for garden forms, but it has no botanical standing.—*E. Röthenbergii* is a garden hybrid of *E. alpinum* and *E. gigantæum*.—*E. azureum* and *E. caelestinum* are garden names without botanical standing; the latter is said to be *E. amethystinum*.—*E. Eburneum*=*E. eburneum* (?).—*E. Wrightii* is said to be a free form of *E. planum*, blooming for a long period.

L. H. B.

**ERYSIMUM** (probably means *blister-drawing*). *Cruciferae*. Of this genus two brilliant yellow and orange, spring- and summer-blooming hardy "annuals," are cultivated, scarcely, if at all, inferior to the true wallflowers (*Cheiranthus*) for general purposes, and a few rock-garden and wild-garden plants.

Biennial, annual and perennial herbs, with long soft appressed 2-parted hairs: lvs. narrow, linear or oblong, entire or variously toothed: fls. orange or yellow, rarely purple, often fragrant; petals 4, usually large, clawed; stamens 6, free and without appendages; style persistent: pod broad-linear, strongly compressed or sometimes 4-angled; seeds many, various.—Species 80-90 in the north temperate zone, being most numerous in Eu. and Cent. Asia. Some of the species are said to hybridize with *Cheiranthus*. Numbers of species are likely to be mentioned as good subjects for alpine-gardening.

Although some of the popular kinds are biennials, the gardeners think of them as annuals. Their seeds can be sown in the fall and produce bloom earlier than if sown in spring. The rock-garden kinds do well also in the front row of the border and on dry banks. They like full exposure to sunlight, and in the spring months are completely covered with bright flowers. Divided plants, as well as seeds, are offered by American dealers.

In general, no special difficulty is experienced with *erysimums*. In Gn. 24, p. 462, it is said that *E. ochroleucum* on level ground is likely to lose its lower lvs. and to perish on heavy soils in hard winters. It thrives best when frequently divided, and may be propagated by cuttings. *E. Barbarea*, Linn., with forms having double fls. and variegated lvs., is *Barbarea vulgaris*.

1418. *Erysimum asperum*. ( $\times \frac{3}{4}$ )

*num*, Nutt.). Lvs. thin, repand-dentate, lanceolate.

*capitatum*, Greene (*E. grandiflorum*, Nutt. *Cheiranthus capitatus*, Douglas). COAST WALLFLOWER. Biennial or perennial, probably usually perennial, erect and leafy and finely pubescent, 1 ft. or less to 2 ft. high, nearly simple or said often to make a much-branched woody plant, with lvs. oblong, oblanceolate or linear and either entire or repand-dentate: fls. light yellow or cream-colored, the petals about 1 in. long with a rounded blade: caps. to 4 in. Seacoast, Calif. to Ore.

*Perofskianum*, Fisch. & Mey. Fig. 1419. Excellent hardy annual, 1-2 ft., erect: lvs. oblong, acute or nearly so, strongly toothed: fls. large, bright orange or reddish orange: pods standing out nearly at right angles, constricted below the narrower style. Caucasus, Afghanistan. B.M. 3757. P.M. 6:245.—There are compact and dwarf strains suitable for edgings (*E. Perofskianum nanum*. *E. nanum compactum aureum*, Gt. 46, p. 194. *E. compactum aureum*, Hort.). Seeds may be sown at different times for succession.

*pulchellum*, Boiss. (*E. laciniatum*, Boiss.). Perennial, green, often caespitose, the st. ascending 2-6 in. or more (even to 2 ft.): lower lvs. oblong-spatulate, dentate or lyrate; upper lvs. sessile, oblong or lanceolate, dentate; lvs. on the suckers lanceolate and often entire: fls. medium, deep orange: caps. erect-spreading, slender. Greece, Asia Minor.—Used as rock-garden plant. There are dwarf forms in the wild.

*ochroleucum*, DC. (*E. rheticum*, DC. *E. helveticum*, DC.). Perennial, 4-12 in.: sts. yellowish, creeping: lvs. oblong-lanceolate, dentate, usually more or less hairy: fls. fragrant, pale yellow, the petals obovate. Eu. Gt. 2, p. 162.—Variable. Forms a turf on rocks and mountains.

*E. Marshallianum*, Andr. Biennial, perennial, 6-8 in. high: lvs. lance-linear: fls. large, bright orange-yellow: used as an alpine. Siberia.—*E. murale*, Desf. Spring-flowering biennial or perennial, 6-8 in., forming a tuft: lvs. deep green, narrow: fls. golden yellow. Eu.

WILHELM MÜLER  
L. H. B.†

*asperum*, DC.

Fig. 1418. Biennial or perennial, height 1-3 ft. in the wild, 12-18 in. in gardens, the sts. erect: lvs. lanceolate to linear, either canescent or thin and green, dentate or entire, upper ones mostly entire, the lowest sometimes pinnatifid: fls.  $\frac{1}{2}$  in. or more across, orange or yellow, seldom purple: pods rough,  $1\frac{1}{2}$ -5 in. long, 4-sided, nearly erect. Que. to Texas and Calif. Var. *arkansanum*, Gray (*E. arkansanum*, Nutt.).

**ERYTHÆA** (one of the Hesperides, Daughter of Evening). *Palmææ*, tribe *Corypheæ*. Palms with solitary, often robust, spineless caudices, ringed at the base, clothed above with dead leaf-sheaths.

Leaves terminal, the younger ones tomentose in some species, glabrous in others, orbicular, flabellately many-parted, the lobes lacerated at the apex, intermingled with fibers, infolded; rachis short; ligule long; petiole stout, slender and arching in some species, smooth or spiny along the margins: spadices usually paniculate, long, white tomentose; branches stout; spathes many, sheathing the peduncle, thick-coriaceous, densely tomentose; bracts and bractlets distinct; fls. pale: fr. globose or ovoid.—Species 5, Mex.

This small group of American palms includes *E. armata*, which is known locally as the "blue palm," and *E. edulis*, the latter commonly known as the "Guadalupe palm," from the fact that it has been found in a wild state only on the island of Guadalupe, off the coast of Lower California. *Erythæas* bear much resemblance to *Brahea*, the segments of the leaves bearing whitish filaments. In the gardens of Santa Barbara, the *erythæas* in a few years form very handsome trees, but in less-favored latitudes they may be cultivated in the same manner as *kentias* or *latanias*, flourishing in a night temperature of 50° to 55° when grown in a rich and open soil and abundantly supplied with water.

A. Fr. more or less globose.

B. Lvs. distinctly glaucous.

*armata*, Wats. (*Brahea armata*, Wats. *B. glauca*, Hort. *B. Roëzlii*, Lindl.). BLUE PALM. Tall and slender, 40 ft. high: lvs. very glaucous; petiole narrow, deeply channeled, margined with numerous stout, more or less hooked, slightly spreading spines; segms. 30-40, sub-lacerate at the apex, slightly filiferous: spadix 18 ft. long or somewhat less, sparingly branched: frs. reddish brown at maturity. Low. Calif. G.C. III. 20:425.

BB. Lvs. green, not glaucous.

*edulis*, S. Wats. (*Brahea edulis*, Wendl.). St. 40-50 ft. high, 15 in. thick, with thick, corky bark: sheaths fibrous; petioles stout, 1 in. wide, plano-convex, unarmed on the acute margins, fibrous-pubescent or glabrate above; ligule 2-3 in. long, densely silky-tomentose; blade 3 ft.; segms. 70-80, at first tomentose, lacerate at the apex and fibrous on the edges: spadices numerous, 5-6 ft. long, branched: fr. shining black. Calif. R.H. 1893, p. 297; 1897, p. 77. G.C. III. 13:507; 22:157.

*Brândeggei*, Purpus. In nature 125 ft. high and having slender trunk: petioles slender, armed with recurved spines; lvs. bright shining green, composed of 10-12 fronded, flabellate lfts.: spadix slightly branched: frs. as in *E. armata*, but somewhat streaked. Low. Calif. Gt. 52, p. 12.—Intro. by Franceschi in 1912, who says, "Appears to grow much faster than other kinds and is not less hardy."

AA. Fr. shaped like inverted pear.

*élégans*, Franceschi. Dwarfier and slower-growing than any other kind: trunk very short: petioles slender, glaucescent, edged

1419 *Erysimum Perofskianum*. ( $\times \frac{3}{4}$ )

with small spines; lvs. somewhat glaucescent on both sides: fl.-spadix 3-4 ft., branched: frs. about  $\frac{3}{4}$  in. diam., yellowish, at first waxy.—According to Franceschi it was first intro. and distributed by the late John Rock of San José, about 1880, and never found again in the wild state, while only one of the plants raised is known to have ripened.

N. TAYLOR.†

**ERYTHRÆA** (Greek, *red*; alluding to the fls. of some species). *Gentianaceæ*. Two outdoor species are in cultivation, with bright deep rose flowers, one of which is a rockery plant from the Azores, the other a Californian annual. Centaurium is name now used.

Small or low herbs, annuals, biennials and perennials with simple and entire sessile opposite lvs., and small or medium-sized 5- or 4-merous, mostly red or pink fls.: calyx-lobes narrow and keeled; corolla salver-shaped; filaments 4 or 5, slender, the anthers becoming twisted; style filiform: caps. oblong or elongated.—About 30 species in the Old and New Worlds; interesting, but little known in cult. Three or 4 small species have been naturalized from Eu.

A light sandy loam, in a protected nook of the rockery, with partial shade, is required for *E. Massonii* (or *E. diffusa*), which is a charming little alpine plant. It must be planted in a well-sheltered position, and requires protection from sun and severe frost in winter, but the little plant is well worth all the extra care one may have to expend on it in winter. Propagated by cuttings, seeds or division. (J. B. Keller.)

**Mássonii**, Sweet (*E. diffusa*, Woods). Height 4 in.: sts. ascending, tufted, not branched above, 1-3-fl.: lvs. fleshy, usually concave, shining: fls. lateral. Azores.—Annuals in Azores, biennial in W. Eu. The plant cult. under this name is considered perennial by our nurserymen.

**venusta**, Gray. Height 6-10 in.: sts. erect, 4-angled, cymosely branched: lvs.  $\frac{1}{2}$ -1 in. long, oblong or ovate-oblong, very blunt: corolla-lobes oval or obovate or oblong,  $\frac{1}{2}$  in. or less long, deep pink; corolla-tube yellowish, about the length of the calyx. Dry hills. Calif. B.M. 6396.

L. H. B.†

**ERYTHRINA** (from Greek for *red*). *Leguminosæ*. CORAL-TREE. Herbs, shrubs or trees, with large and showy papilionaceous flowers, for planting out and for greenhouse bloom; and open-ground subjects in Florida and California.

Erect, or the herbs more or less reclining, usually spiny: lvs. alternate, pinnately 3-foliate, with small glanduliform stipules: fls. mostly red and in dense racemes; calyx 2-lipped or oblique; standard free or very nearly so, erect or spreading; tenth stamen free, or united only half its length: fr. a slender, more or less twisted pod; seeds mostly ovoid.—Known species about 50, in tropical and warm temperate regions around the world.

Erythrinæ are much prized garden plants. Some of them, particularly the herbaceous kinds, are frequently planted out in the summer. In the house they demand an intermediate temperature. Give rich soil and frequent waterings. In the woody species, aim to have well-ripened wood for flowering, for the bloom is produced on wood of the preceding year. The herbaceous species are propagated by division of the rootstock; also by cuttings from shoots springing from the old roots. Woody species are propagated by cuttings of growing wood. All species are propagated by seeds, whenever these are obtainable. Many species have been more or less grown or tried within the limits of the United States; some of them fail to bloom in southern California, probably because of insufficient summer heat. The forms more or less in cultivation are likely to be imperfectly or doubtfully determined botanically. Some of the erythrinæ are used as shade for coffee and cacao plantations.

**A. Herbaceous species (or treated as such).** These die down at the end of the season, and the roots may be stored after the manner of dahlias. It is best to start the roots before planting them out, particularly in the N. In their native countries, these species are more or less woody.

**Crista-gállii**, Linn. (*E. laurifolia*, Jacq.). COMMON CORAL-TREE. Bushy and woody, sometimes developing a very short trunk, but the flowering branches dying back after blooming, the stronger branches coming annually or periodically from near the root: st. and petioles somewhat spiny: lfts. ovate-oblong or lance-oblong, acuminate, entire: fls. large, brilliant crimson, the keel nearly as long as the down-folding standard, the wings rudimentary. Brazil. B.M. 2161. B.R. 313. L.B.C. 3:296. G. 4:451. G.W. 3, p. 437; 6, p. 281. F.E. 16:637 (var. *compacta*).—Runs into many forms, varying in the shade of red, some of them with variegated lvs. South of Washington, it stands out-of-doors if protected. In the N. the fleshy roots are taken up and stored. Valuable for summer bloom. Fls. in large, terminal racemes. Madame Belanger is a popular garden form. **E. compácta**, Bull. of very compact habit and fls. rich crimson is probably a form of this species.

**speciosa**, Andr. Bush-like, reaching 8-12 ft., but usually cut back as *E. Crista-gállii* is: sts. and lvs. prickly: lfts. broad and more or less 3-lobed, pointed, veiny: fls. in pubescent racemes, rich crimson. W. Indies. B.R. 750.—St. green, very prickly.

**herbacea**, Linn. Perennial: sts. several and herbaceous, from a very thick root, 2-4 ft. high, the flowering ones nearly leafless: lfts. 3, ovate to hastate; petioles long, more or less prickly: fls. 2 in. long and very slender, deep scarlet, in loose racemes 1-2 ft. long: seeds scarlet. N. C. to Texas and W. Indies. Common on Gulf coast of Ala. and Miss. B.M. 877. **E. Bidwillii**, Lindl., is a beautiful hybrid of this species and *E. Crista-gállii* (the latter the pollen parent), with herbaceous shoots and an ascending vexillum. B.R. 33:9. H.F. 2:48.

**AA. Woody or tree-like species.** Greenhouse plants, or planted in the open in S. Calif. and S. Fla.

**Humeana**, Spreng. (*E. cæffa*, Ker-Gawl, not Thunb.). Often tree-like and 30 ft. or more, the st. and petioles very spiny: petioles long; lfts. rhomboid-ovate, acuminate: peduncles axillary and strictly erect, longer than the lvs., white-warty; fls. verticillate-spiked on the ends of the peduncles, long and slender, deflexed, brilliant scarlet fading to purple. S. Afr. B.M. 2431. B.R. 736.

**Coralodéndron**, Linn. CORAL-TREE. Tree, prickly: petioles not armed; lfts. ovate-rhomboid: calyx campanulate, the teeth obsolete; standard erect, linear-oblong, scarlet: seeds scarlet, usually with a black spot. W. Indies. L.D. 3:170.—The handsome deep scarlet large fls. are borne in long racemes after the lvs. fall.

**velútina**, Willd. Prickly tree: lfts. scurfy-tomentose beneath, broadly ovate, obtuse, the terminal deltoid-ovate: calyx split nearly to base, the 5 teeth minute; standard orbicular, reflexed (1-1½ in. long), the wings nearly as long as calyx, the keel-petals distinct and small: pod velvety, few-seeded. Jamaica to Brazil. B.M. 3227.

**índica**, Lam. (*E. cárnea*, Blanco). Tall tree with very small usually black prickles and thin gray bark: lfts. rhomb-ovate, membranous and glabrous: fls. showy scarlet, in dense short racemes; calyx split nearly to base; standard ovate-oblong and blunt or nearly so, slightly recurved, 2-2½ in. long, and about half as broad, much exceeding the wings and keel; wings and keel nearly equal, not more than half so long as the calyx: pod 6-12 in. long, torulose. India, Polynesia, W. Indies. Variable. Var. **pícta**, Hort (*E. picta*, Linn.), has variegated lvs. Var **Parcéllii**, Hort (*E. Parcéllii*, Bull), has lfts. with variable yellow varie-

gation: fls. bright cinnamon-red. G.C. II. 1874 (2): 393. G.Z. 18:64; 21, p. 2. By some, *E. picta* is accorded specific rank and *E. Parcellii* is united with it. Var. *marmorata*, Hort. (*E. marmorata*, Veitch), has large lvs. attractively spotted with white. G.Z. 24, p. 73.

*fusca*, Lour. Tree-like, 8 ft., the bark fuscous (brownish), bearing short prickles, the branching diffuse: lvs. unarmed; flts. lanceolate, entire, glabrous: fls. brown-red, in terminal racemes; calyx somewhat bilabiate, the lips entire and erect; standard very long, obtuse, convolute in a tube; stamens long, connate at base: pod long, terete, articulate, pilose; seeds oblong. Cochin-China.

*Poeppigiana*, Cook (*Micropteryx Poeppigiana*, Walp. *E. Micropteryx*, Poepp.). BUCARE. Used for shading coffee and cacao in the W. Indies: tree 40-60 ft., the prickles short: lvs. large, apparently not prickly; flts. broad, entire, with nectaries at base of the 2 lower petiolules: fls. cinnamon-red; calyx truncate; standard plane, elliptic or narrow-oval, to  $1\frac{1}{8}$  in. long; wings small, about twice exceeding the calyx, obovate or oval-elliptic; keel scarcely shorter than standard, arcuate. Probably Peruvian.—Offered in S. Fla. The *E. umbrosa* of the W. Indies is probably this species.

1420. *Erythronium americanum*.  
( $\times \frac{1}{2}$ )

*flabelliformis*, Kearney. Shrub or small tree, to 10 ft.: sts. velvety white when young, bearing stout curved prickles below the lf.-axils: lvs. canescent when young, usually prickly; flts. firm, fan-shaped or deltoid-ovate, usually broader than long, rounded at apex: fls. bright scarlet, crowded in short terminal racemes, numerous, pedicels velvety-canescant; calyx campanulate, truncate, usually somewhat oblique, white-tomentose; standard exceeding the calyx, about  $1\frac{1}{2}$  in. long, linear-oblong, narrowed at both ends; wings and keel short: pod linear, torose; seeds oval, bright scarlet with whitish hilum. S. E. Ariz.—Offered in S. Calif.

*E. arborea*, Small (*E. herbacea* var. *arborea*, Chapm.). Shrub or small tree, to 20 ft., armed: lvs. with wire-like petiole and rachis; flts. deltoid or hastately 3-lobed: fls. scarlet in racemes 4-8 in. long: pod 3-5 in. long, constricted between the seeds. Fla. Likely to be planted.—*E. bogotensis* appears in a European trade list of greenhouse plants.—*E. constantiana*, Mich. Tree, soft, the trunk thick and spiny: fls. large, scarlet, in racemes. Eu.—*E. insignis*, Tod. Tree, sparingly prickly: flts. ovate, tomentose when young: fls. scarlet, in short and dense racemes. Origin unknown. Gt. 28: 988.—*E. vespertilio*, Benth. Shrub, for a warm greenhouse: glabrous, branches prickly: lvs. not prickly; flts. broad-cuneate at base, 3 or 4 in. broad, usually 3-lobed, and the middle lobe of various shape and sometimes absent: fls. showy (red?) and many in racemes; standard ovate, recurved at top, nearly  $1\frac{1}{2}$  in. long; wings small, oblong:

pod long, torulose; seeds few, large and red. Austral. G.Z., 30, p. 1.—*E. viarum*, Tod. Tree, prickly: flts. rhombic-ovate, tomentose when young, terminal one long-stalked; fls. scarlet, in many-fld. short racemes, the standard obovate. Origin unknown.

L. H. B.

ERYTHROCHÆTE, or ERYTHROCHÆTON: *Ligularia japonica*.

ERYTHRONIUM (from the Greek word for red, applied to the purple-rose European species). *Liliacæ*. DOG'S-TOOTH VIOLET (although in no sense a violet). ADDER'S-TONGUE. Small spring-flowering hardy scapose bulbous plants.

Erythroniums have bulbs standing erect and from oblong to linear in form, 2 radical lvs., which in most species are handsomely mottled: scape slender and leafless, producing from 1 to many nodding very attractive fls.; perianth of 6 similar divisions, usually recurved; stamens 6 and a single 3-lobed style: fr. an oblong or obovoid more or less 3-angled loculicidal caps.—Handsome plants of the north temperate zone. One belongs to the Old World, 4 to E. N. Amer., 2 are found in the Rocky Mts., while in the cool woods and high mountains from N. Calif. to the British possessions the genus is represented by about 9 species and a number of well-marked varieties. The species are confused or variable. The first and perhaps second year from seed, the plants bear a single lf. and do not bloom. Some of the species spread in large patches, by means of underground stolons. The bulb is scaly outside but with a solid interior, being really a corm.

The erythroniums are most interesting spring flowers. They succeed in any light soil, particularly in partial shade. In common with all herbaceous perennials, especially those that produce bulbs or corms, they profit by a winter mulch of leaves or litter.—The western erythroniums are all plants of the cool woodlands, except a few that grow at such altitudes as to reach like conditions. They thrive best in shade, a thoroughly drained soil, moist and rich in mold, a surface covering of half rotten leaves tending to equalize conditions. Any good fibrous material, as fibrous peat, coconut fiber or spent tanbark, or even well-rotted sod, will answer the purpose to lighten the soil and give that abundance of mold they delight in. Pockets in shaded rockwork give ideal situations. They will thrive naturalized on cool wooded slopes; and where the drainage is good they will thrive in grass. The leaves ripen before the grass is cut and the effect is very good. Simply planted in boxes in a loose soil, rich in mold, and left year after year in a shaded spot, they sometimes give splendid bloom. *E. Hartwegii* flowers very early, and stands more heat and dryness than any other variety. *E. purpurascens* and *E. montanum*, from high altitudes, tend to throw up their growth very late, and are on that account rather difficult to cult. All of the western species are very satisfactory garden plants.—The propagation of *E. Dens-Canis* and varieties, the eastern American species and *E. Hartwegii*, is by offsets. All of the other western species can be increased only by seeds. The eastern species should be planted at least 5 inches deep. When planting erythronium bulbs, cover with 2 inches of earth; as the bulbs themselves may be 2 inches long, this means that the holes should be 4 inches deep.

#### INDEX.

giganteum, 6, 10.	minus, 6.	

**A. OLD-WORLD ERYTHRONIUMS.** *Fls. always solitary, and without a crest near base of inner petals: lvs. handsomely mottled: offsets few.*

1. **Déns-Canis**, Linn. St. 4-6 in. high: lvs. oval-acuminate, rounded at the base, blotched or patched with reddish brown: fls. drooping, rose-colored, rose-purple or lilac; segms. strongly reflexed, narrow, long-pointed. Cent. Eu., Japan, in several forms. Gn. 76, p. 649.—Variations are white, rose-colored or flesh-colored. Var. *longifolium*, Hort., varies in its narrower lvs. and larger fls; var. *majus*, Hort., is apparently a form of this. Var. *sibiricum*, Hort., from the Altai Mts., is taller. The species thrives in a moist open garden soil, and exposed to the sun. Often used in rock-gardens. Little known in American gardens.

**AA. EAST-AMERICAN ERYTHRONIUMS.**—*Fl. solitary, without a crest on inner petals: mostly producing offsets.*

2. **americānum**, Ker. COMMON ADDER'S-TONGUE. Fig. 1420. Scape 6-10 in., from an ovoid bulb that produces offshoots: lvs. elliptic- or oblong-lanceolate, mottled with purple-brown and whitish: fls. yellow, the segms. recurved, the 3 inner ones auricled at base; stigmas united. E. Canada, to Fla. and Ark., in rich low grounds, particularly in or near woods. Runs into many forms. The following names belong with it: *E. lanceolatum*, Pursh; *E. angustatum*, Raf.; *E. bracteatum*, Boott.

3. **albidum**, Nutt. WHITE ADDER'S-TONGUE. Producing offshoots: lvs. not mottled, narrow: fls. pinkish white, yellow at base; segms. recurved, not auricled; stigmas spreading. Ont. and N. Y. to Minn. and Texas.

4. **mesachœreum**, Knerr. Without basal offshoots: lvs. not mottled, narrowly oblong to linear-lanceolate: fls. lavender, the segms. not recurved; stigmas spreading; earlier than the last. Iowa to Kans. and Mo.

5. **propüllans**, Gray. Bulb ovoid: offshoots arising from near middle of the st.: lvs. small, green or slightly mottled: fls. rose-colored, with yellow base; style slender and stigmas united. S. Ont. and Minn.

**AAA. WEST-AMERICAN ERYTHRONIUMS.**—*Fls. 2-4, sometimes more (rarely only 1-fl.).*—The lvs. are richly mottled, except in *E. grandiflorum*. The corms do not produce offsets, except in *E. Hartwegii*. Inner petals with auricles, except in *E. Howellii*. All except *E. purpurascens* have large and showy fls.

*B. Style 3-cleft.*

6. **grandiflorum**, Pursh (*E. giganteum*, Lindl.). Scape 1-2 ft. high: lvs. broadly lanceolate, to 6 in. long, acute and short-cuspidate, unmottled: scape slender, 3-5-fl.; fls. very bright yellow; petals recurved; anthers yellow. E. Ore. to Brit. Col. Var. *album*, Hort. (*E. montanum*, Hort.). Like the type, except the fls. are white, yellowish at center, and with a slight greenish cast. Var. *minus*, Morr., is smaller.—*E. grandiflorum* grows from very high mountains to (at one point) little above the sea-level. In cult. the high mountain form starts very late and is difficult to grow, while the sea-level form (var. *robustum*, Purdy) is an easy subject. In some localities the anthers are red, as in var. *Nuttallianum*, Purdy (*E. Nuttallianum*, Schult.), in others both red and yellow, but as a rule yellow. The so-called var. *minor* is small merely from less favorable situation. By some, the *E. giganteum*, Lindl., is kept distinct. G.C. III. 43:212. J.H. III. 58:397. G.M. 53:359.

7. **parviflorum**, Goodd. The Cent. Rocky Mt. form of *E. grandiflorum*: scape 4-12: lvs. oblong, tapering both ways: fls. usually solitary, bright yellow, greenish in the bottom; segms. lanceolate-acuminate, about 1 in. long, strongly recurved; anthers pale yellow.—A sub-alpine species.

8. **californicum**, Purdy. Lvs. richly mottled: fls. few to as many as 16; petals revolute and broader, creamy to light yellow, deeper at the center and often marked maroon at base. In the Coast Ranges of Calif., San Francisco Bay to Humboldt Co.—In cult. the most satisfactory East. The description of *E. revolutum* var. *Watsonii* in Cyclo. Amer. Hort., also covers *E. californicum*. G. 32:424.

9. **Hartwegii**, Wats. Bulb-bearing offsets freely on filiform stolons from the base: lvs. mottled: fls. 1-6, mostly in a sessile umbel, large, light yellow-orange at center and white or cream-color above. Foothills of the Sierra Nevada Mts. in Calif. G.C. III. 20:361; 43:215.—The plant appears to have several scapes because the umbel is sessile but each fl. is on a pedicel.

10. **revolutum**, Smith. Lvs. 1-4, mottled in white and light brown: fls. nearly always 1 or 2; petals narrow and curved; style large and stout; filaments from subulate (awl-shaped) to deltoid, opening from white flushed with pink to pinkish purple, becoming purple. J.H.

III. 35:523; 43:268. Var. *Bolanderii* is not separable from the type. *Pink Beauty* is a soft pink form found in Humboldt County, Calif. Var. *albiflorum*, Hort. (var. *Watsonii*, Purdy. *E. giganteum* var. *albiflorum*, Hort. *E. grandiflorum* var. *albiflorum*, Hook.). Fls. pure white with a greenish cast, often banded maroon at base; petals slender; a very beautiful plant. B.M. 5714. F.S. 20:2117. G.C. III. 3:556; 15:621. Var. *Johnsonii*, Purdy (*E. Johnsonii*, Bolander). Very similar to the type, but lvs. mottled in dark brown and looking as if coated in varnish, and fls. dark rose with orange center. Gn. 51:136. G.C. III. 19:549; 25:253. Var. *præcox*, Purdy. Lvs. mottled in mahogany, the most beautifully of any erythronium: the fls., usually 2-4, are creamy white with orange center.

11. **montanum**, Wats. Scape slender, to 18 in., 1-3-fl.: lvs. not mottled, broad-lanceolate to nearly ovate, contracted into a winged petiole; perianth pure white, orange at base. On high mountains of Ore. and Wash.—Very difficult to cult. as the bulbs start very late; one of the most beautiful.

*BB. Style not divided.*

12. **citrinum**, Wats. Rather stout, to 10 in., 1-9-fl., the fls. close together and opening at about the same time: lvs. mottled, very broad-lanceolate, obtuse and short-apiculate, attenuate to a very short petiole: petals broad, strongly recurved, light yellow, orange at center, the tips becoming pink. S. Ore. Gn.M. 6:65.

13. **Hendersonii**, Wats. Fig. 1421. Slender, to 12 in., 1-3-fl.: lvs. mottled in dark brown, lanceolate to oblong, obtuse and short-apiculate, narrowed to a short petiole: petals strongly recurved, pale purple, with a very dark purple, almost black, center. S. Ore. G.F.

1421. *Erythronium Hendersonii*. ( $\times \frac{1}{2}$ )

1:317 (adapted in Fig. 1421). G.C. III. 3:653; 15:623; 43:213. Gn. M. 6:65. Gn.W. 22:375. B.M. 7017.

14. *purpurascens*, Wats. Lvs. undulate, not mottled but shaded in dark metallic tints: fls. small, spreading, crowded in a raceme, light yellow (almost white), center orange, becoming purplish. Sierras.—A very small-fl. erythronium, with 1-8 fls. crowded together. This species grows at 5,000-7,000 ft. altitude in the Sierras. While under some conditions it is low-growing, under other conditions it equals in size and height the most robust species. At the lower altitudes of its habitat snow covers the ground until early May and this plant flowers shortly afterward; it remains very dry in summer and fall.

15. *Howellii*, Wats. Rather slender, to 18 in., 1-3 fld.: lvs. mottled, lanceolate to oblong-lanceolate, usually acute and short-apiculate: fls. pale yellow with orange base, becoming pinkish. S. Ore.—Of the Pacific coast erythroniums, this alone is destitute of the ear-shaped appendages at inner base of petal.

CARL PURDY and L. H. B.

**ERYTHRÓXYLON** (Greek, *red wood*; true of some species). Written also *Erythroxyllum*. *Erythroxyllaceæ*. COCA. A genus famous for the coca plant, the leaves of which are of vast importance in medicine, yielding cocaine, grown slightly in the extreme south of Florida and California, and rarely cultivated under glass in the North for its economic interest.

Erythroxyton comprises about 90 species of shrubs or small trees widely distributed in tropical and subtropical countries but most abundant in Trop. Amer.: lvs. alternate, entire, often coriaceous: fls. small, whitish, on bracteolate pedicels, solitary or fascicled; sepals 5 (or 6); petals of same number, deciduous, appendaged on the inner face; stamens twice the number of petals, connate at base: fr. a 1-seeded drupe.

**Côca**, Lam. Shrub, 5-6 ft. high, with rusty brown, slender branches, on the extreme tips of which the lvs. are borne: below the lvs., on the wood of the preceding year, which is reddish, clusters of 3-5 yellow 5-lobed fls.  $\frac{1}{4}$  in. across spring from the protection of the small scales that line the branchlets, and which are colored like the bark: lvs. oval, obovate or elliptical, differing in different cult. strains or varieties, about  $1\frac{1}{2}$ - $2\frac{1}{2}$  in. long and marked on the under side with 2 lines extending on either side of the midrib from base to apex. Native country uncertain; the earliest described form, which happens to be Peruvian, was named by Lamarck *Erythroxyllum Coca*, and figured in B.M. 7334. The lvs. of this form are about  $2\frac{1}{2}$  in. long, oblong-obovate, tapering to a short stalk, rounded at the apex, the midrib extending beyond into a short, sharp point. Coca is grown commercially on a large scale throughout S. Amer., and also in Java and Ceylon. There are 2 leading commercial varieties, according to Kraemer,—the Bolivian or Huanco, and the Peruvian or Truxillo. The lvs. are picked when fully grown, and quickly dried in the sun. The shrub is said to require for its best development a very humid atmosphere and comparatively high elevation. Coca should not be confused with cocoa and cacao, which are discussed under Theobroma.

L. H. B.†

**ESCALLONIA** (named for Escallon, a Spanish traveler in South America). *Saxifragaceæ*. Mainly evergreen shrubs or small trees, widely dispersed in South America, especially in the mountains.

Leaves alternate, glandular-serrate (rarely entire): fls. strongly odorous, white or of a pink or red color, in terminal racemes or panicles, or axillary; calyx-lobes 5; petals 5; stamens 5; style simple, the stigma obscurely 4-5-lobed and peltate, or 2-lobed and reniform or peltate. Noteworthy in the genus are the glands, stalked or not, which may occur almost anywhere on the plant. Lvs. often with resinous dots on

one or both surfaces.—About 45 or 50 species, a number of which have been intro. in the S., and in Calif. They are of easy culture; rapid growers; and often artificially trained as vines. Several will probably prove half-hardy as far north as N. Y.

1422. *Escallonia langleyensis*.

**A. Lvs. large, hairy, especially below, or in one variety glabrous but very shiny.**

**pulverulenta**, Pers. Shrub: lvs. very thick, oval or elliptic, obtuse, serrate, rough-hairy below, with scattered hairs above: fls. white, in long densely fld. terminal racemes; stigma distinctly 2-lobed, reniform: fr. a glandular-warty caps.: branches hairy. Var. **glabra**,

Engler. Differs from the species in being almost or quite glabrous. Handsomer than the type. Not in cult. in this country.

**AA. Lvs. glabrous or nearly so.**

**B. Fls. red or pink.**

**rùbra**, Pers. var. **glabriuscula**, Hook. & Arn. (*E. rùbra* of many authors). Dainty fld. shrub, with numerous stalked glands: lvs. ovate, often deltoid-ovate, acute, finely and irregularly doubly-serrate, glabrous, with brown resinous dots below, rather small: fls. red, tubular, borne in 2's or 3's (or rarely singly) on lateral pedicels, grouped near the ends of the branches; calyx densely glandular; petals long-clawed; stigma obscurely 5-lobed: fr. a top-shaped caps. B.M. 2890.

**macrantha**, Hook. & Arn. Shrub: lvs. thickish, broadly ovate, acutish or obtuse, bluntly serrate, essentially glabrous: fls. red, long-tubular, in a stocky, often branching, terminal raceme; calyx-lobes with marginal glands; stigma peltate, obscurely 5-lobed: fr. a glabrescent caps. F.S. 6:632.—Excellent. Var. **sanguinea** is a horticultural variety with fls. more crimson.

**organensis**, Gardn. Half-hardy S., 2-5 ft., glabrous throughout: lvs. thick, oblong, acutish, serrulate, with tiny resinous dots: fls. pink, in close, terminal clusters. B.M. 4274.—Excellent. Organ Mts., Brazil.

**BB. Fls. white, or, in *E. langleyensis*, rose-tinted.**

**C. Width of lvs. more than  $\frac{1}{2}$  in.**

**chlorophylla**, Cham. & Schlecht. (*E. càndida*, Lem.). Shrub, to 3 ft.: lvs. oblong-ovate or obovate, obtuse, apiculate, or more rarely acute, with a few blunt teeth on upper part, or wholly entire: fls. white, in a terminal, many-fld. panicle. J.F. 403.

**montevidensis**, DC. (*E. floribunda*, Reichb. *E. floribunda*, HBK. var. *montevidensis*, Cham. & Schlecht.). Shrub, to 9 ft.: lvs. thick, elliptic, obtuse, finely serrate, glabrous, shiny above: fls. white, in a terminal, many-fld. panicle; petals clawed; stigma obscurely 4-5-lobed: fr. a top-shaped caps., crowned by the obviously longer style. G. 25:576; 27:465.

**floribunda**, HBK. Shrub: lvs. oblong-ovate, obtuse, very minutely crenulate-serrate or entire, glabrous or nearly so: fls. white, in many-fld., compound, axillary or terminal panicles; petals clawed; stigma peltate, 2-lobed: fr. a caps., crowned by the equal or barely longer style. G.C. III. 47:53.

cc. Width of lvs. not over  $\frac{1}{2}$  in.

*leucantha*, Remy. Densely lvd. shrub: lvs. obovate, obtuse or nearly so, finely serrate, at least on upper part, glabrous, small: fls. white, in very dense racemes; petals spatulate, clawed: fr. an obovate caps.

*virgata*, Pers. (*E. Philippiana*, Mast. *E. virgata* var. *Philippiana*, Engler. *E. stricta*, Gay). Densely lvd. shrub, half-hardy south of Washington: lvs. stiff, lanceolate or obovate, obtuse to acute, tapering at base, with minute rather distant teeth on upper part, glabrous or nearly so, small: fls. white, axillary, scattered, or sometimes massed near the tips of the branchlets; petals spreading, scarcely if at all clawed: fr. a globose caps. G. 27, p. 464. Gn. 66, p. 64.

*langleyensis*, Vilm. & Bois. Fig. 1422. A graceful shrub (artificial hybrid of *E. macrantha* and *E. virgata*): lvs. linear-ovate, obtuse or acutish, minutely serrulate, small, in short racemes at the ends of the branchlets.

*E. alba*, a name found in some of the catalogues, is not determinable.—*E. pendula*, Pers. Shrub with red fls., in narrow racemes to more than 1 ft. long, and lvs. resembling those of tobacco. Desirable.—*E. rosea*. An unidentified catalogue name which in at least one instance, certainly does not refer to *E. rosea*, Griseb., a very little known species.

ALBERT HANFORD MOORE.

**ESCHSCHÖLTZIA** (J. F. Eschscholtz, of Kotzebue's scientific expedition). *Papaveraceæ*. Brilliant and popular garden flowers.

Low, pale or glaucous herbs, annual or perennial, with ternately dissected alternate lvs., and large, showy yellow or whitish long-peduncled fls.: sepals 2; petals 4; stamens numerous; stigmas 4-6: caps. long and slender like a silique, 1-loculed, elastically dehiscent at the instant it separates from the receptacle. The calyx forms a hood which is pushed off over the bud as the petals expand (see detail at the left in Fig. 1423). The torus or receptacle (from which the caps. arises) is prominently hollowed and surrounds the base of the pistil.—Few genera have been more diversely interpreted as to the limits of species. Gray accepted about a dozen species, and something like this view of the genus is commonly held. Greene, however, in Pittonia, V (1905) recognized 112 species and separated one of the described species under the new genus *Petromecon*. Fedde in Engler's Pflanzenreich, hft. 40 (1909), separates 123 species. These many species are segregated largely from the multifarious group to which the name *E. californica* has been applied. On this treatment Jepson writes: "This species is highly variable, especially so in trivial details of leaf-segmentation and of shape of calyptra and in habit. It is also variable in the size and color of petals and so runs into an extensive concourse of forms, many of which seem obviously seasonal or due to soil or moisture conditions. Some of these highly marked plants in the Sacramento Valley have two seasonally dimorphic forms, an erect vernal flowering form with very large golden corolla and huge torus rim, and an autumnal flowering form with small straw-yellow corolla and reduced or no torus rim. It has been found impossible thus far, after several trials, to reproduce this sequence in cultivation on the coast. The flower is not like either the vernal or autumnal form but approximates the coast form. A large number of the wild forms have been collected but probably only a small proportion of those in existence. Yet the number of specimens distributed to herbaria has been sufficient to form the basis for nearly 100 new species. It does not seem hopeful that the solving of the problem of *Eschscholtzia californica* in just this way will lead either to permanent results or afford a satisfactory basis for the kind of work most needed, namely the prosecution of combined field and cultural studies." Studies of growing plants under conditions of observation and control, both of wild and horticultural material, are awaited. Where the abundant garden material falls, in the segregations, is yet unknown. The cult. forms are derived from the old

*E. californica*, and *E. tenuifolia* appears also to be in the trade. *Eschscholtzia* is a genus of W. N. Amer., ranging both on the coast and in the interior valleys, and in the Sierras. It occurs from Low. Calif. to the valley of the Columbia River, in New Mex., Ariz., Nev., Utah. It has run wild in parts of Cent. Eu.

*californica*, Cham. CALIFORNIA POPPY. Fig. 1423. Perennial, but cult. as an annual, 10-24 in. high, forming mats: lvs. long-petioled and divided into linear parts, those on the sts. smaller and shorter-petioled: fl. saucer-shaped, opening in sunshine, 2-3 in. across, yellow or orange or cream-colored: pod 3-4 in. long, strong-ribbed: torus large and funnel-shaped. Calif. and Ore., mostly along the coast.—One of the most popular garden fls. It is treated as a hardy annual, the seeds being sown where the plants are to stand, and they should be sown very early. It stands considerable cold, and blooms after the first frosts. If well protected, plants of one season's growth will pass the winter and give some bloom the following spring. It sometimes self-sows. Very attractive as an edging, because of its interesting bluish foliage. There are double-fl. forms. Very variable, and cult. under a variety of names, as *C. maritima*, Hort. (nct Greene), *C. varia*, Hort. (trade name for mixed varieties), *C. aurantiaca*, Hort., *C. alba*, Hort., *C. Thórburnii*, Hort. In color forms are offered yellow, golden yellow, white, rose-white, carmine, rose. Var. *crœcea*, Hort. (*E. crœcea*, Benth.). Fls. deep orange: torus very widely expanded: calyx-bud long-attenuate. B.R. 1677. B.M. 3495. Var.

1423. *Eschscholtzia californica*. ( $\times \frac{1}{2}$ )

*Douglasii*, Gray (*E. Douglasii*, Benth.). Rather more slender, and blooms earlier: fls. pure yellow: torus rim narrow.

*tenuifolia*, Hook. Lower, with narrow lvs. in a radial tuft, the long divisions being almost capillary: fls. small (1 in. across), light yellow, overtopping the lvs.: torus less prominent: seeds muricate. Foothills of the Sierra Nevada. B.M. 4812.

L. H. B.

**ESCÓNTRIA** (named for Señor Don Blas Escontria, of Mexico). *Cactaceæ*. Large, much-branched cacti. Ribs few: areoles narrow, bearing pectinate clusters of spines: fls. small, yellow, diurnal: fr. and ovary covered with chartaceous, translucent, persistent scales, without hairs or spines; fr. fleshy, edible; seeds black. For cult., see *Succulents*.

**chiotilla**, Rose (*Cereus chiotilla*, Web.). Sixteen ft. or more high: ribs mostly 7: radial spines 10-15; central 1-2, the upper one 2 in. long, curved downward: fr. 1 in. diam. Mex.—Rare in cult. J. N. ROSE.

**ESPALIER**, a trellis or open support on which a tree or woody plant is trained in formal shape and to a given number of branches, usually in a vertical plane; and also the plant so trained. Apple trees and others are often trained as espaliers in Europe; the tree may be transplanted and subsequently attached against a wall or building, or it may be kept permanently on the trellis or open support. Sometimes espalier-training is employed only when the tree or bush is young, for the purpose of bringing it into shape and to prepare it for a wall or other support. Trees are trained on espaliers also to give them full exposure to the sun on all sides, to regulate the fruit-bearing and to provide easy means of controlling insects and diseases. Espalier-training is most frequent in cool and cloudy regions, in those in which space must be utilized to the utmost, and where hand-skill is obtainable or is relatively cheap.

There are many forms of training. The plant may be trained to a single shoot, or to two shoots lying in opposite directions, mostly horizontal, in which case it is called a cordon; or the top may be spread fan-shaped on the trellis, or in other forms, and it may then be called an espalier. The training is begun when the plant is very young—perhaps only a year or two from the graft or bud—and before it has produced a stiff trunk and unmanageable head. Usually the branching is started within a foot or so of the ground by heading back the main stem; and as many shoots as may be desired on the trellis are allowed to grow. These shoots are tied to the trellis or posts as they grow, and the side shoots are pinched out except such as are desired for further arms in the framework or for fruit-spurs. The trellises themselves may be of wire strung on posts, or the tree may be tied from post to post or stake to stake set close together. Espaliers are little used in this country, and then only in small gardens, and mostly when a trained gardener is employed.

L. H. B.

**ÉSULA**: *Euphorbia*. The *E. cristata* of the trade is probably the cristate form of *Euphorbia lactea* or similar species.

**ETHERIZATION OF PLANTS**. Etherization, as applied to plants, means strictly the forcing of a dormant plant into growth by subjecting the plant to ether vapors at certain concentrations in a closed chamber for a definite period of time, usually twenty-four to seventy-two hours. The plant after such treatment is placed under environmental conditions favorable for growth. Since in practice the use of chloroform is similar in its application and effects, it will be discussed here. The general nature of etherization was first noted by Johannsen in 1890, and following his investigation a wide stimulus was given to the commercial forcing of flowering shrubs. For other methods of forcing a dormant plant, see *Rest-period*.

Before discussing the method of etherization, its effects and application, it is necessary first to have some idea of what is meant by the term rest-period or the condition of dormancy.

#### *Rest-period.*

Perennial plants, especially those in the temperate regions, in general have a season of growth and active metabolism followed by a period of quiescence as

regards any outward manifestations of metabolism. During this period, not all of the vital processes are at a standstill and changes in the reserve food may be in progress, but the plant appears to be at rest and is dormant. The rest-period begins with the advent of the unfavorable growth conditions of the autumn, and normally continues until the favorable conditions of the spring.

One might reasonably assume that growing perennial plants removed from out-of-doors at the approach of autumn conditions to a greenhouse, would continue growth and not pass into the rest condition. One might assume, also, that if a plant in a dormant condition be brought into favorable conditions it would resume growth immediately. But experience and investigations show that many plants will not immediately continue growth, and, provided they do continue growth, it is at a slower rate. Dormant plants, that is those in the rest-period, may require considerable time before resuming growth. There are some plants that during dormancy respond quickly when brought into the greenhouse; there are others that remain dormant despite the most favorable environmental conditions. The rest-period in various species of *Acer* (maple), of *Quercus* (oak), of *Fraxinus* (ash), and of *Fagus sylvatica*, as well as other plants, is so well fixed as to make it almost impossible to force the dormant plants into growth by warmth and moisture alone. Special treatment is necessary, such as etherization. There are other plants in which the rest-period is not well established. These quickly respond to favorable growth conditions normally prevailing in a greenhouse. In many plants this rest-period has attained an almost habit-like character. The following table with data taken from results secured by Howard with branches brought into the greenhouse at Halle, Germany, is instructive:

GROWTH RESPONSE OF BRANCHES WHEN BROUGHT INTO GREENHOUSE.

Species	Collected Oct. 20–Nov. 4, 1905. No. of days for beginning of growth	Collected Jan. 8–10, 1906. No. of days for beginning of growth
<i>Acer negundo</i> var. <i>versicolor</i> .....	63	20
<i>Acer pseudoplatanus</i> ....	0*	0
<i>Azalea mollis</i> .....	26	0
<i>Æsculus Hippocastanum</i> ..	0	20

<i>Berberis vulgaris</i> .....	10	3
<i>Celastrus scandens</i> .....	0	17
<i>Cercis canadensis</i> .....	0	10
<i>Cydonia japonica</i> .....	6	7
<i>Deutzia gracilis</i> .....	10	3
<i>Fagus sylvatica</i> .....	0	38
<i>Lonicera tatarica</i> .....	7	3
<i>Magnolia acuminata</i> .....	29	25
<i>Populus canadensis</i> .....	61	20
<i>Quercus macrocarpa</i> .....	59	0
<i>Spirea sorbifolia</i> .....	1	

\*0=No growth

In the investigation made by Howard, 234 species were collected from October 20 to November 4, and of these only 125 grew; and of the 125, only 18 per cent began growth within a period of nine days. Between January 8 to 10, another collection was made including practically all the species of the first lot and others in addition, so that the number totaled 283 species. Of this number 244 grew, of which 50 per cent began growth within the first nine days. The species that did not grow when brought into the greenhouse January 8 to 10 made growth when brought into the greenhouse on February 26. From these and the results of other experiments the conclusion is drawn that plants in general tend to pass out of the rest condition as the

season advances toward the spring. Dormancy is less stable in January than in November. This condition holds true not only for woody plants but also for bulbs and other herbaceous plants.

#### Method of breaking the rest-period.

The one method which has been largely employed for forcing dormant plants into growth is the etherization method. An air-tight chamber is provided, the size depending on the quantity or size of the material to be treated. The plants being placed in the chamber, it is tightly sealed except for a small opening through which ether may be introduced. Usually just below this opening is placed a sponge on which the ether is poured and then the opening is again sealed. If one desires to etherize a few bulbs, a wide-mouth bottle of two quarts capacity may be employed and the ether added in a small vial and the bottle then tightly stoppered. Special etherizing chambers are described for commercial work. The main desideratum is to have a chamber that will not permit of leakage of the ether vapor. The stopper must be securely fastened or weighted down.

**Quantity of ether.**—The quantity of ether best employed in forcing plants may vary with the nature of the plant, the season of the year, and the temperature of the etherization chamber. In general, the quantity to be added varies from 5 to 15 cubic centimeters per cubic foot of space (10 cubic centimeters equal about one-third fluid ounce). Early in the rest-period at 60° F., one should use about 15 cubic centimeters per cubic foot of space. In the middle of the rest-period, one should employ less and the amount should be further decreased toward the end of the rest-period. If the relative humidity of the chamber is high, a slight increase in the quantity of ether may be made. If chloroform is used, the quantity should be one-fourth to one-third of the quantity of ether recommended. The following figures are from Stuart:

#### TREATMENT RECOMMENDED FOR PLANTS AT DIFFERENT SEASONS

Cubic centimeters per cubic foot

	Ether		Chloroform	
	Cc. used	Exposure hours.	Cc. used	Exposure hours.
Lilac—				
October .....	15	48-24-24	4	48-24-24
November .....	12	48-24-24	3 ½	48-24-24
December .....	10	48-24-24	3	48-24-24
January .....	..	..	..	..
Astilbe—				
October .....	15	48-24-48	4	48-24-48
November .....	15	48-24-24		48-24-24
December .....	12	48-24-24		48-24-24
January .....	10	48	3	48

**Time of exposure.**—The time of exposure is also variable, being of greater duration in the early part and shorter in the latter part of the rest-period. In the early rest-period, a long exposure is given, varying from forty-eight to seventy-two hours to even as much as ninety-six hours. In case of long exposure, the practice is usually followed of making a forty-eight-hour exposure, after which the plant is removed from the etherization chamber for a day and then re-etherized for another twenty-four-hour period. Toward the middle and late rest-period, the time of exposure may be shortened as well as the quantity of ether.

#### The results.

The effect of etherization is to shorten the rest-period of the plant. Etherized plants come into bloom earlier and may be forced at lower temperature than unetherized plants. Howard found that seventy species

of woody plants collected December 17 to 24 and etherized for forty-eight hours, opened their buds fully in an average of 20.3 days, while the untreated plants required an average of 28.1 days for the same development. Many experiments have been made with lilacs. Jannvek states that lilacs etherized August 24 were in bloom September 18.

The following table compiled from results secured by Stuart show conclusively the value of etherization with lilacs:

#### INFLUENCE OF ETHER AND CHLOROFORM ON LILACS

Date of treatment	Substance employed	Dosage cc. per cubic foot	Expos. hours	Full bloom in days	
				Charles X	Marie Legraye
Nov. 18-22....	None	..	..	51	30.5
Nov. 18-22....	Ether	12	48	31	29.5
Nov. 18-22....	Chloroform	3.6	48	31	28.5
Dec. 17-21....	None	..	..	31	29.5
Dec. 17-21....	Ether	15	48	31	29.5

In the foregoing table it is noted that treatment in the middle of December resulted in no beneficial effect. The plants at the time were in the middle rest-period, when growth-response requires no strong stimulation outside of normal growth conditions.

In general it may be stated that lilacs if etherized before December 1 will respond markedly to the influence of etherization. General results show that etherized lilacs blossom in seventeen to twenty-five days. The saving in time may be eight to twenty days.

Favorable results have been secured with flowering shrubs. Positive results have been reported frequently for *Azalea mollis*, for *Viburnum* and *Astilbe*. Negative or slight results have been reported for *Deutzia gracilis*, *Prunus triloba*, roses, and *Spiraea prunifolia*. Similar results have been reported for lily-of-the-valley.

The method of action of the ether is not understood and any discussion of the subject is yet hypothetical.

#### Etherization of bulbs.

On the forcing of bulbs the evidence is unsatisfactory. At the Cornell Station, positive results were reported (see Bailey, "Cyclopedia of Agriculture," Vol. II: 29), but more recently Stuart has reinvestigated the forcing of bulbs and finds conflicting results. He states that the etherization of bulbs is not commercially practicable. Some unpublished data on the etherization of bulbs at the Cornell Station sustain this conclusion. Theoretically, those results are to be expected because the bulbs in practice are gathered in the late spring or early summer and then stored for months. After planting, the bulb is allowed to remain in a cold-frame for several months so that when brought into forcing conditions it is well over the rest-period and, indeed, has probably passed through its period by the time it is first planted.

**Effect on rhubarb.**—Some positive results have been secured at the Vermont Agricultural Experiment Station with etherization of rhubarb. Different lots of rhubarb were etherized on December 9, January 9 and February 24. The first gave an increase over the control of 34.4 per cent, the second 89.7 per cent and the third 5.7 per cent.

**General conclusions.**—Certain general rules may be applied to the practice of etherization:

1. Etherization shortens the rest-period.
2. The more resistant a dormant plant is in growth-response to favorable environmental conditions, the greater will be the advantage of etherization.
3. Etherization becomes of less value as the end of the rest-period is approached.

4. It is wasted effort to etherize a plant that readily responds in growth to the normally favorable growth condition.

LEWIS KNUDSON.

**ETROG.** This name is applied by the Jews to a citron (*Citrus Medica*, Linn.), which is imported and used by them for religious ceremonies connected with the Feast of the Tabernacles. The etrog and the lulab (palm leaf with myrtle and willow branches) are carried and waved during the services, especially those of thanksgiving. Since the time of the anti-Jewish demonstrations in Corfu in 1891, the etrog is imported more largely from Palestine than from that island. In addition to the use of the etrog by orthodox Jews for religious ceremonies, the natives of Palestine make salads of the fruit. See *Citron*.

WALTER T. SWINGLE.

**EUCALÝPTUS** (Greek, *eu*, well; *kalypto*, to cover as with a lid: the petals and usually also the calyx-limb fused and covering the flower before anthesis, then falling off in the form of a lid, or cover). *Myrtaceæ*. GUM-TREE. Plate XXXIX. Mostly trees, frequently of immense size, a few of the alpine and sub-alpine species shrubby, much grown in California and the Southwest for their ornamental value, as windbreaks and avenue trees, for fuel, and especially for their timber.

Leaves simple, entire; in the seedlings and on young shoots of many species horizontal, opposite, sessile, and cordate; in the adult mostly vertical, alternate, petiolate (rarely opposite and sessile), and varying from roundish to lanceolate-acuminate and falcate; always rigid, penniveined, glabrous except rarely on the young shoots, sometimes covered with a glaucous wax: fls. white, rarely yellowish or some shade of red, in umbels of 3 to many, rarely solitary, the umbels solitary and axillary or paniculate or corymbose; calyx-tube obconical, campanulate, ovoid, or oblong, adnate to the ovary at the base; petals and calyx-lobes connate, forming a lid, or cap, which separates from the calyx-tube by a circumscissile dehiscence; lid sometimes plainly double, the outer cap then derived from the calyx-limb, the inner cap from the petals; stamens numerous; anthers small; style undivided: fr. a caps. partially or wholly inclosed in the adherent calyx-tube, opening at the top by 3-6 valves; seeds numerous, small, mostly angular.—About 300 species, all native of Austral. and the Malayan region. Related to *Angophora* and to *Syncarpia*, but distinguished by the absence of distinct petals.

The genus *Eucalyptus* was monographed in part by Baron von Mueller in his *Eucalyptographia* (cited here as F. v. M. Eucal.), in which 100 species are illustrated (1879-84). The genus is now receiving exhaustive treatment by J. H. Maiden in his "Critical Revision of the Genus *Eucalyptus*," appearing in parts, with numerous plates. This author also furnishes the best information regarding the uses and timber of the various species, in his "Native Useful Plants of Australia." Bentham described 135 species in his "Flora Australiensis," vol. 3 (1866). The Australasian Association for the Advancement of Science published a very useful key by J. G. Luehmann in 1898. The most exhaustive American work on the genus is United States Forestry Bulletin No. 35, "Eucalypts Cultivated in the United States," by A. J. McClatchie. University of California Agricultural Experiment

Station Bulletin No. 196, by Norman D. Ingham, is a practical guide for planters, with descriptions of the more important species. The United States Forest Service, the California Station, and the California State Board of Forestry have all issued smaller bulletins on this subject. Inflated claims have been made for eucalyptus culture, and authentic publications should be secured if one contemplates planting them extensively.

*Eucalyptus* is a group adapted to semi-tropical and warm temperate regions. But few species are really hardy. *E. globulus* has been very widely distributed over the globe through the persevering efforts of the late Baron von Mueller; it is frequently planted in the malarial regions of warm climates, as at the Campagna at Rome, with very beneficial effect. (Sanitarians will be interested in "Eucalyptus in Algeria and Tunisia, from an Hygienic and Climatological Point of View," by Edward Pepper, Proc. Amer. Phil. Soc. 35:39-56.) In England, the same species is grown extensively for subtropical gardening, on account of its distinctive glaucous hue and symmetrical growth, but in that climate it needs the protection of glass in winter.

This is by far the most important genus of timber trees introduced into California. The ordinary blue-gum, *E. globulus*, has been grown in large numbers and is still the favorite for general planting. Its hard and durable wood is replacing oak and hickory to some extent for insulator pins, wheel-wrights' work, flooring, tool-handles, and furniture. Although pale in color, it takes a good polish, possesses a beautiful grain, and is readily stained. Furniture made from blue-gum wood and properly stained has every appearance of mahogany. The chief drawback to the use of eucalyptus for lumber is the tendency of its logs to end-check while curing, thus involving considerable waste. As a windbreak and fuel tree it is unsurpassed, since it is of rapid, erect growth and the timber is easily split. Its foliage has been distilled in large quantities for the oil it contains, practically all of the eucalyptus oil now sold in the United States coming from home-grown trees.

In addition to the blue-gum, *E. rostrata* and especially *E. tereticornis* are grown for railroad ties, piling, interior finish and furniture. *E. resinifera* is a hardy eucalypt yielding a good timber not so liable to check as that of some others; it has been but little grown in America thus far. *E. corynocalyx* is a good drought-resistant species for districts with mild winters, and its wood is of the best. *E. crebra* will grow under a greater range of conditions than perhaps any other and is especially suited to the hot and dry interior valleys. Other drought-resistant eucalypts are *E. microtheca* and *E. polyanthemos*, while the most resistant to frost are *E. crebra*, *E. rostrata*, *E. tereticornis*, *E. globulus*, *E. viminalis*, *E. rudis*, *E. robusta*, and *E. resinifera*. The species most cultivated as ornamentals are *E. ficifolia*, *E. leucoxylon*, *E. sideroxylon* var. *rosea*, *E. Risdonii*, *E. erythronema* and *E. polyanthemos*. Persistently repeated accounts of heights ranging from 325 to 500 feet for certain eucalypts are erroneous, as indicated under *E. amygdalina* var. *regnans*.

Although the eucalypts are not exclusively, and some species not even prominently horticultural, yet because of the great general interest attached to them and because of their varied uses, it is thought best to discuss them rather fully in this Cyclopaedia.

#### Culture of eucalyptus in California.

The following directions for the propagation of *Eucalyptus* are adapted very largely from Bulletin No. 196 of the California Experiment Station, entitled "Eucalyptus in California," by Norman D. Ingham (1908).

The necessary conveniences for the propagation of

XXXIX. *Eucalyptus viminalis* in California.

the seedlings are: seed-boxes or flats, a good soil, seed true to name, plenty of convenient water, and in most localities shade for the young plants. The seeds of most species may be gathered at all times of the year, although the greater amount mature during the summer and fall. The seed-cases should be gathered from the trees when the valves begin to open and placed on sheets of canvas in the direct rays of the sun, which will open the valves, allowing the seed and chaff to fall out. The number of fertile seed to the pound is very high; the average number of transplanted plants raised to the pound is 12,000. Eucalyptus seed will germinate and grow in nearly any soil but the best results are secured when the seeds are sown in a light loam, while a medium loam mixed with about one-quarter well-rotted horse-manure should be used in the transplanting flats.

The time to sow the seed varies somewhat with the locality, but as a general rule the seed should be sown in May or June and the seedlings from these sowings will be large enough to be set out in the field the following spring, if they receive proper care while young. The seed is usually sown broadcast in the seed-flats

1424. *Eucalyptus ficifolia* ( $\times \frac{1}{4}$ ). No. 2.

and the young plants transplanted once before being set in the field. Some persons take the trouble to sow one seed in a place and space them in the flats; by this method transplanting is unnecessary. Others sow the seeds in hills and practise thinning, instead of transplanting before setting out in the field. This last method is used in the warmer districts with good success, because of the great trouble experienced in transplanting during the hot summer months. Whichever method is used, fill the flats to a depth of 3 or 4 inches with the prepared soil, pressing it down firmly in the boxes, then sow the seeds and cover them to a depth of about  $\frac{1}{8}$  inch with the same soil, sand, or sawdust, pressing this covering firmly over them. The seed-flats should be kept damp through the heat of the day, until the young plants break the ground, then care must be taken not to use too much water and that there is a good circulation of air over the flats, or damping-off is liable to occur. This disease can be prevented by using practically no water on cloudy days and only in the mornings on clear days. If the seeds are sown broadcast in the flats, when the young plants have reached a height of 2 to 3 inches, they can be transplanted to other flats of prepared soil and spaced from  $1\frac{1}{4}$  to 2 inches apart. The best results in transplanting are secured if the plants are hardened-off for a few days beforehand by checking the water supply, allowing them to become quite dry. The soil into which the young plants are transplanted should be kept damp, and the plants should be protected from the direct rays of the sun for a few days. The lath-house or the screens are necessary to supply shade for the young

plants and will also protect the seeds in flats from the ravages of birds and the young plants from the frosts during winter months, before the time for setting in the field.

The time to set the plants in the field varies with the climatic conditions or localities and whether the plants are to receive irrigation or not. In localities in which frosts are common through the winter months, it is advisable to set the trees out as early in the spring as possible without endangering them to a late frost and still have them receive the benefit of the late rains, so that they will have a full season's growth to withstand the frosts of the following winter. If the trees are to be irrigated, they may be set out later in the season without danger of loss from want of moisture. To insure a good stand, the plants should not be under 6 or over 20 inches in height when set in the field; to a certain extent, the smaller the plants when set out, the better the results afterward, although the size varies somewhat with the species and the locality. In many species the roots are as long if not longer than the plant's own height above ground. This is a family of plants that will not stand a large amount of mutilation to the root-system; consequently better results are secured from setting out small plants.

If the soil is heavy rich loam, the trees may be planted as close as 6 by 6 feet apart unless irrigation is to be practised. In the latter case, 4 by 8 feet would be the right distance, thus leaving an 8-foot space for plowing out the irrigating-ditches each year. If it is a lighter soil on which the planting is to be made, 8 by 8 feet is the proper distance, or 6 by 10 feet, if irrigation is to be practised. The close planting has a tendency to sacrifice the diameter growth in favor of the height, also making more erect trees and forming a perfect canopy with their crowns that will shade the soil, nearly preventing evaporation, as well as any vegetable growth on the forest floor. Close planting matures a greater number of perfect trees, and is especially recommended when straight poles are desired. The plants should be blocked out in the flats before being brought into the field, by drawing a sharp knife between the rows. If care is taken to set out the young plants with this small amount of soil around the rootlets, the shock caused in transplanting is reduced to a minimum. Each planter should carry a trowel, to make the holes that are to receive the young plants at the intersection of the marked lines. These holes should be of such a depth that the plants can be set from  $\frac{1}{2}$  to 1 inch lower in the soil than they originally were in the flats. Each plant should have the soil pressed firmly about it and receive a small amount of water, unless the soil is moist from recent rains.

In order to provide a mulch, thus checking evaporation and also to kill the weeds, cultivation should be conducted in the new plantation as long as possible without danger of injuring the young trees by driving a horse between them. The plantings generally may be cultivated for the first season and part of the second before the limbs of the trees spread out and interlap so that it is impossible to drive between the rows. It is an acknowledged fact that the only way to secure a good stand, and give the trees a start, is to cultivate and take care of the plantings from the time of setting out. However, a number of groves have been set out on land that is too hilly or rocky to cultivate and the trees have made fair growths.

Thinning of the young trees is an important practice, as it is not good management to set out just the number of trees that one expects to mature. A planting upon any good soil may with advantage be set out 6 by 6 feet apart (1,210 trees to the acre), and at the end of the first year a rigid thinning should be started, removing with a grub-hoe all weak, inferior, or injured trees. This thinning should be conducted until only the strong and healthy trees, or a certain number,

remain to the acre. By this method some trees will stand at the original distance that they were planted, while others will stand at multiples of that distance. The extra cost of close planting will never be noticed when the largest possible stand of healthy trees is guaranteed, which is practically the case under this method. If thinning is carried out by a set plan, removing every other one or two trees, many strong and healthy trees will be sacrificed. All limbs that have a tendency to deform the trees should be removed each year. After the third or fourth year, the trees will have grown to such a height that to remove the limbs may prove impractical in most cases. At this period (the fourth or fifth year) there enters a new problem: the removal of the poorer trees for wood and stakes to allow the remainder a larger area of soil to draw upon and a greater space above ground to extend their branches. At this time the trees on an acre can be reduced to a certain number, leaving these to grow for telephone poles, ties, and lumber, or the entire grove may be cut for stakes and wood.

*Second-growth eucalyptus.*—In three to six weeks after the trees have been felled, the sprouts will start out from the stumps. These sprouts are produced in abundance and if properly thinned will soon replace the cut forest, thus providing a second growth of fuel or timber in much less time than was required with the original grove. These remarks apply probably to all species of eucalyptus, certainly to all sorts experimented with in California up to the present time.

#### Taxonomy of the cultivated eucalypti.

All of the keys used for the identification of species are more or less artificial. No satisfactory natural classification has yet been devised. While the following key is designed to aid in the making of determinations rather than to express relationships, species known to be closely related are placed near each other in the text so far as this can be conveniently done. For the ready determination of species in this critical genus, it is necessary to have adult leaves, buds, flowers, and mature fruit; immature fruits are often very misleading. Allowance should always be made for extreme forms, since only normal specimens are here described. This applies particularly to size of leaves. Unless otherwise stated, the leaf description is drawn from foliage on mature stems. The juvenile foliage, i.e., on young seedlings and on suckers, is usually very different, the leaves often broader, blunt, sessile, and of a different color.

#### KEY TO THE SPECIES.

- A. Fls. mostly in panicles or corymbs, not simple umbels (occasionally the infl. appears to be paniculate in section AAA also, owing to dropping of lvs., so that it is well to look for lf-scars in doubtful cases).
- B. Fr.  $1\frac{1}{2}$ –2 in. long; valves inclosed: fls. large.
- C. Seeds black, not winged: fls. white or pink..... 1. calophylla
- CC. Seeds brown or red, winged: fls. red (pink to crimson or scarlet)..... 2. ficifolia
- BB. Fr.  $\frac{1}{2}$ –1 in. long ( $\frac{1}{4}$ – $\frac{1}{2}$  in. in E. maculata); valves inclosed: fls. medium.
- C. Lvs. paler beneath: fls. in terminal corymbs..... 3. corymbosa
- CC. Lvs. of nearly equal color on both sides: fls. in lateral and terminal panicles.
- D. Caps. slightly ribbed: fls. nearly or quite sessile in the clusters... 4. eximia
- DD. Caps. smooth: fls. distinctly stalked..... 5. maculata
- BBB. Fr.  $\frac{1}{4}$  in. or less long (nearly  $\frac{1}{2}$  in. in var. of No. 16); valves various: fls. small.
- C. Shape of lvs. orbicular to ovate, often nearly as broad as long.
- D. Petioles slender; lvs. alternate.
- E. Fls. stalked: lvs. dull grayish green..... 6. polyanthemos
- EE. Fls. nearly sessile: lvs. lustrous and dark green..... 7. populifolia
- DD. Petioles none; lvs. opposite.... 8. melanophloia
- CC. Shape of lvs. lanceolate or oblong, elongated.
- D. Lvs. distinctly paler beneath than above.
- E. Fr.-valves included in the calyx-tube..... 10. paniculata
- EE. Fr.-valves exerted..... 11. Ravertiana
- DD. Lvs. of equal color on both sides.
- E. Lid  $\frac{1}{4}$  in. or more long, beak-like..... 9. siderophloia
- EE. Lid shorter, not beak-like.
- F. Fr.-valves much exerted, spreading..... 12. microtheca
- FF. Fr.-valves about reaching the rim: lf.-veins very diverging..... 13. crebra
- FFF. Fr.-valves wholly included in calyx-tube: lf.-veins very oblique.
- G. Lid hemispheric..... 15. bicolor
- GG. Lid conic..... 16. hemiphloia
- AAA. Fls. solitary in the lf.-axils, or in strictly sessile umbels, large.
- B. Lvs. all opposite, cordate at base: shrub..... 17. macrocarpa
- BB. Lvs. mostly alternate, not cordate.
- C. Peduncles ascending, or fls. entirely sessile; lid warty.
- D. Plant a tree: lvs. acute..... 18. globulus
- DD. Plant a shrub: lvs. obtuse, very oblique at base..... 19. alpina
- CC. Peduncles recurved, flat; lid smooth: shrub..... 20. tetraptera
- AAA. Fls. in stalked umbels.
- B. Fl.-stalks (either pedicels or peduncles) flattened.
- C. Fr.-valves with teeth projecting well beyond calyx-rim.
- D. Teeth connivent into a cone: lid  $1\frac{1}{2}$  in. long.
- E. Fr. not embedded in receptacle. 24. cornuta
- EE. Fr. partly embedded in receptacle..... 25. Lehmannii

- DD. Teeth distinct: lid  $\frac{3}{4}$  in. or less long.
- E. Fr.  $\frac{1}{2}$ – $\frac{3}{4}$  in. long: lid about  $\frac{1}{2}$  in. long.
- F. The fls. sessile in the umbels: lvs. obtuse.....26. *platypus*
- FF. The fls. pedicellate: lvs. acute.....27. *occidentalis*
- EE. Fr. smaller: lid shorter.
- F. The fls. more than 3 in each umbel.
- G. Lid much longer than calyx-tube.....43. *resinifera*
- GG. Lid about as long as calyx-tube.....41. *punctata*  
42. *saligna*
- GGG. Lid much shorter than calyx-tube: fls. sessile.....33. *Cambagei*
- FF. The fls. usually 3 in each umbel.....52. *viminalis*
- CC. Fr.-valves included or scarcely exerted beyond the calyx-rim (exserted but closely incurved in *E. megacarpa* and *E. gomphocephala*).
- D. Breadth of fr. less than  $\frac{1}{2}$  in.
- E. Lid less than half as long as calyx-tube, depressed-hemispheric, blunt.
- F. Lvs. mostly 2–4 in. long: lid very short.
- G. Fr. 3–6 lines diam.: lid granular.....28. *coccifera*  
29. *virgata*
- GG. Fr. about 2 lines diam....40. *microcorys*
- FF. Lvs. mostly 4–8 in. long.
- G. Veins very oblique; lvs. mostly under 1 in. wide.
- H. Calyx not angular; outer stamens sterile.30. *hæmastoma*  
31. *Sieberiana*
- HH. Calyx very angular in bud; stamens all perfect.....32. *goniocalyx*
- GG. Veins at nearly a right-angle to midrib; lvs. thick, more than 1 in. wide.....34. *botryoides*
- EE. Lid at least half as long as calyx-tube, mostly conic and acute.
- F. Lvs. ovate-lanceolate,  $1\frac{1}{2}$ –3 in. wide; lateral veins widely spreading.....35. *robusta*
- FF. Lvs. lanceolate,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. wide; lateral veins oblique.
- G. The fls. short-stalked.
- H. Arrangement of lvs. opposite: umbels bent downward.....70. *doratoxylon*
- HH. Arrangement of lvs. alternate.
- I. The lid narrowly conic, twice as long as calyx.....36. *redunca*
- II. The lid broader, not so long.....37. *pilularis*  
38. *Muelleriana*  
39. *acmeniodes*  
41. *punctata*
- GG. The fls. sessile in the umbel: lvs. paler beneath.42. *saligna*
- DD. Breadth of fr. over  $\frac{1}{2}$  in.
- E. Lid not or scarcely broader than calyx-tube.
- F. Lvs. roundish, obtuse.....26. *platypus*
- FF. Lvs. lanceolate, acute.
- G. Calyx-tube and lid very warty.....18. *globulus*
- GG. Calyx-tube and lid ridged or nearly smooth.
- H. Caps. sunk in the calyx-tube.....46. *incrassata*  
47. *Planchoniana*  
21. *cosmophylla*
- HH. Caps. protruding from calyx-tube.....48. *megacarpa*
- EE. Lid much broader than calyx-tube.....49. *gomphocephala*
- BB. Fl.-stalks cylindric or angular but not flattened.
- C. Caps. sessile or nearly so in the umbels.
- D. Fr.-valves with conspicuous projecting teeth.
- E. Lid 1– $1\frac{1}{2}$  in. long, cylindric....24. *cornuta*
- EE. Lid mostly  $\frac{1}{4}$ – $\frac{1}{2}$  in., conic.
- F. The fr.-valves merely acute....50. *rudis*
- FF. The fr.-valves ending in needle-like points.....51. *decipiens*
- EEE. Lid short, rarely  $\frac{1}{4}$  in. long.
- F. Buds ovoid, smooth.
- G. Fr. mostly 4-celled: fls. usually 3.....52. *viminalis*
- GG. Fr. mostly 3-celled: fls. usually more than 3....53. *Stuartiana*  
54. *Macarthuri*
- FF. Buds club-shaped, slender, often rough.....55. *amygdalina*
- DD. Fr.-valves included, or barely exceeding the rim.
- D. The fls. 4 or more.
- F. Lvs. of equal color on both sides.
- G. Venation of lvs. feathered.
- H. Fr.  $\frac{3}{4}$ –1 in. wide: shrub.61. *buprestium*
- HH. Fr.  $\frac{3}{4}$ – $\frac{1}{2}$  in. wide: trees.
- I. Buds club-shaped (i.e. widest above the middle), obtuse.....55. *amygdalina*  
56. *Risdonii*  
57. *obliqua*
- II. Buds ovoid, acute: fr. contracted at orifice.44. *piperita*  
45. *eugenioides*
- GG. Venation of lvs. longitudinal and almost parallel.....58. *stellulata*  
59. *coriacea*
- FF. Lvs. paler beneath.
- G. Lid broader than calyx: fr. streaked lengthwise...60. *corynocalyx*
- GG. Lid not broader than calyx: fr. not streaked...62. *diversicolor*
- EE. The fls. 1–3 in each umbel.
- F. Lvs. opposite, heart-shaped at base.
- G. Calyx obtuse at base: lvs. crenate.....22. *cordata*
- GG. Calyx tapering at base: lvs. entire.....23. *pulverulenta*
- FF. Lvs. scattered, narrowed at base.
- G. Fr. scarcely contracted at orifice.....21. *cosmophylla*
- GG. Fr. much contracted at orifice.....61. *buprestium*
- CC. Caps. plainly stalked in the umbels.
- D. Umbels with more than 3 fls.
- E. Fr.-valves plainly exerted.
- F. Fr. flat-topped; valves awl-shaped.....63. *salmonophloia*
- FF. Fr. rounded to the valves; valves triangular, acute.
- G. Diam. of fr. 2–3 lines...64. *rostrata*  
65. *tereticornis*
- GG. Diam. of fr. 4–6 lines.
- H. Anthers reniform.....66. *macrorhynchus*
- HH. Anthers oblong.....50. *rudis* [cha]
- EE. Fr.-valves included.
- F. Fr. scarcely or not at all contracted at orifice.
- G. Lvs. thick, odorless: fr.  $\frac{1}{4}$  in. across.....67. *Gunnii*
- GG. Lvs. thin: fr. slightly smaller.....68. *melliodora*  
69. *odorata*
- FF. Fr. contracted at orifice.
- G. Lvs. opposite.....70. *doratoxylon*
- GG. Lvs. mostly alternate.
- H. Breadth of fr. about  $\frac{1}{4}$  in.

ridges broader than in other ironbarks: lvs. 4-7 in. long; lid beak-like, very acute,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long; stamens about 3 lines long; anthers minute, globular, opening by oblong slits: fr. obovoid, truncate, about  $\frac{1}{4}$  in. across, the valves slightly protruding. Oct., Nov. F.v.M. Eucal. 4:8. Maiden, Crit. Rev. Eucal. 47 (figs. 19-33).—Wood heavy, strong, and durable, useful for wagon work, tool-handles, building, posts, poles, and the like. Fls. provide honey for bees. Tree of rapid growth and resistant to extremes of temperature: grown in the San Joaquin Val'ey.

10. *paniculata*, Smith. WHITE IRONBARK. RED IRONBARK. Tall or medium-sized tree: bark hard, persistent, deeply furrowed, of a grayish brown color: lvs. lanceolate, acuminate, 3-5 in. long: fls. in panicles or sometimes in axillary umbels; lid variable; stamens 2-4 lines long, the outer ones sterile; stigma dilated: fr. truncate-ovate, pedicelled, 2-4 lines wide, with thin rim. Summer. F.v.M. Eucal. 5:8. Maiden, Crit. Rev. Eucal. 57 (figs. 8-21).—Wood usually very pale, but variable; the hardest of ironbarks; "cuts almost like horn:" valuable for railroad-ties, fencing, and building purposes. Does not endure heat and drought: much prized in Austral., but trees in Calif. are not promising.

11. *Raveretiàna*, F. v. M. Tall tree with thin angular branchlets: bark deciduous, leaving the branches smooth and gray, but often persistent on the trunk: lvs. lanceolate, opaque, 3-5 in. long: fls. exceedingly small, white, short-stalked; lid slenderly conic, under 2 lines long; stamens not 2 lines long; anthers reniform, opening by longitudinal slits: fr. little over 1 line wide, low-cup-shaped, the protruding valves forming a hemispheric summit. F.v.M. Eucal. 1:8. Maiden, Crit. Rev. Eucal. 53 (figs. 1-3).

12. *microtheca*, F. v. M. Tree, becoming 80 ft. high: bark rough, gray, persistent, or the outer layers deciduous, leaving the trunk smooth: lvs. narrowly lanceolate, 4-6 in. long: lid broad-conic; stamens very short; anthers minute, roundish, opening by longitudinal slits: fr. scarcely  $\frac{1}{2}$  in. wide; valves fully half-protruding. F.v.M. Eucal. 10:6. Maiden, Crit. Rev. Eucal. 52 (figs. 16-22).—Not yet fully tested in Amer.: endures frost and heat: recommended as a forest cover for the hot dry region of the S. W.: the roots yield water to natives and travelers on the Australian deserts. Wood beautifully colored but perhaps too hard for cabinet work.

13. *crebra*, F. v. M. NARROW-LEAVED IRONBARK. Small to large tree, with slender drooping branchlets: bark persistent throughout, hard, dark, ridged and deeply furrowed: lvs. pale, narrow, linear-lanceolate; lateral veins fine, nearly parallel, widely diverging from the midrib: lid conical or nearly hemispheric, not over 2 lines long; stamens 1 or 2 lines long, inflexed in bud; anthers globular, opening by longitudinal slits: fr. obovoid-truncate, not over 2 lines wide, the tips of the valves not or scarcely exerted. F.v.M. Eucal. 5:3. Maiden, Crit. Rev. Eucal. 53 (figs. 4-9).—A rapidly growing frost-resistant tree of picturesque habit: endures minimum temperatures of 18-20° and maximum temperatures of 110-118° (McClatchie), not very resistant to alkali (Loughridge). Grown in Calif. for its hard durable wood, of a reddish color. Bark sometimes described as grayish and deciduous.

14. *leptophleba*, F. v. M. Characters as in *E. crebra*, but fls. somewhat larger and fr. 3 or 4 lines wide: lvs. of a silky sheen.—This has been classed as a var. of *E. drepanophylla*, F.v.M., but the two are now known to be identical and *E. leptophleba* is the older name.

15. *bicolor*, A. Cunn. (*E. largiflora*, F. v. M.). BLACK BOX. Shrub or small tree, with drooping branches: bark persistent, rough and hard: lvs. lanceolate, 5 in. or less long; lateral veins at an acute angle

to midrib: lid double, the inner one hemispheric; stamens 1 or 2 lines long; anthers opening by lateral pores: fr. truncate-ovate, about 2 lines wide, the valves inclosed but not distant from the thin rim. F.v.M. Eucal. 5:7. Maiden, Crit. Rev. Eucal. 49 (figs. 5-13), 51 (figs. 9-19).—Timber hard, tough, and durable, rather

1426. *Eucalyptus globulus*. Shoots on a young plant. ( $\times \frac{1}{4}$ ) No. 18.

easily worked: suitable for ties, piles, shafts, poles, cogs, and the like.

16. *hemiphloia*, F. v. M. AUSTRALIAN GRAY BOX. Tree, 90 ft. or less high: bark of trunk persistent, solid, grayish and somewhat wrinkled; of branches deciduous in flakes or long strips: lvs. lanceolate-falcate to ovate-lanceolate, 3-5 in. long, thick and rigid, often ashy gray; lateral veins distant, diverging at a very acute angle: lid conical; stamens pale, about 2 lines long; anthers globular, opening by lateral pores: fr. ovoid-oblong, truncate and slightly contracted at orifice, about 3 lines wide. F.v.M. Eucal. 5:5. Maiden, Crit. Rev. Eucal. 50 (figs. 1-6).—Useful as a shade tree because of its dense foliage; also for fuel and as pasturage for bees. Wood hard, tough, and durable.

Var. *albans*, F. v. M. (*E. albans*, Miq.). WHITE BOX. Bark dull green, persistent: lvs. glaucous or white-mealy: buds chalk-white: fr. larger.

17. *macrocarpa*, Hook. Stout shrub, 6-15 ft., usually white-mealy: lvs. all opposite, sessile, cordate-ovate: fls. orange-colored to crimson, very large, solitary; calyx-tube smooth or obscurely ridged; lid conical, longer than the tube; stamens about 1 in. long: fr. depressed-hemispherical,  $1\frac{1}{4}$ -3 in. across, with raised rim and broad protruding valves. Hook. Icon. 405-407. B.M. 4333. F.v.M. Eucal. 8:4. Maiden, Crit. Rev. Eucal. 77 (figs. 1-3).—Desirable ornamental because of its glaucous foliage and brilliant bloom: grown sparingly in S. Calif.

18. *glóbulus*, Labill. BLUE GUM. Figs. 1425-1427. Tree, 300 ft. or less high: bark deciduous in long thin strips or sheets, leaving the trunk smooth and grayish or bluish white except at base: lvs. lanceolate, thick, often  $\frac{1}{2}$ -1 ft. long; those on young shoots and seedlings opposite, sessile, broad, and white-mealy: fls. solitary or 2 or 3 together, closely sessile or on a short peduncle; calyx-tube and lid warty, covered with bluish white wax; stamens above  $\frac{1}{2}$  in. long: fr. angular,  $\frac{3}{4}$ -1 in. across, the flat valves not pro-

truding. Dec.-May. F.v.M. Eucal. 6:2. G.C. II. 15:621; III. 2:777, 784; 10:737. Gn. 71, p. 18; 75, p. 606. Maiden, Crit. Rev. Eucal. 79 (figs. 1-12).—The best species for general planting; extensively used in Calif. Its combination of rapidity of growth, straightness of trunk, great strength of wood, and its known ability to flourish under a wide range of conditions in Calif., give it a great advantage over any other species (Ingham). Wood stronger than that of *E. rostrata* and *E. tereticornis*, yellowish white, easily stained, not durable in the soil in Calif.: used there for insulator pins, spokes, tellos, whiffle-trees, handles, flooring and interior finish; a good species for fuel: logs check badly in curing, this much less in the so-called "San José blue-gum" or "re-enforced gum" which, however, is thought by some to be only a selection of the best trees of ordinary blue-gum. Lvs. distilled for oil: fls. yield much honey to bees, but because of its pronounced flavor there is little or no demand for it in retail trade (Richter). Endures minimum temperatures of 25° and high temperatures of the San Joaquin and Sacramento Valleys but not of the desert districts: resists considerable drought when once established but best development is attained only on good and fairly deep soil. Fig. 427 shows the stamens and the structure of the bud. Nos. 1-4 are half natural size; 5 is on a larger scale. No. 4 is a section of a bud.

Var. *compácta*, Hort. DWARF BLUE GUM. Densely branched from the ground, forming a symmetrical rounded compact tree: lower foliage as in young growth of *E. globulus* but smaller with the longer narrower lvs. only near the top.—Said to have originated near Niles, Calif., from seed of the ordinary blue-gum (Calif. Nursery Co.).

The specific name *globulus* is sometimes written with a capital G, because it is a noun rather than an adjective; but the initial letter is here written in lower case in accordance with a recommendation of the International Botanical Congress.

19. *alpina*, Lindl. Shrub, 12 ft. high: lvs. inequilaterally semi-ovate, blunt, acute on young shoots, 2-4 in. long, thick and leathery: fls. sessile in the lf.-axils, solitary or few: fr. hemispherical,  $\frac{3}{4}$ -1 in. wide, not angular; rim broad; valves protruding. Sept.-Nov. F.v.M. Eucal. 2:1.

20. *tetráptera*, Turcz. Shrub or small tree: branches often sharply angled: lvs. very thick, oblong-lanceolate: fls. solitary, on flat recurved peduncles; lid 4-angled, much shorter than calyx; stamens not over  $\frac{1}{2}$  in. long: fr. prominently 4-angled, 2-3 in. long,  $\frac{3}{4}$ -1 in. wide, the valves well inclosed. F.v.M. Eucal. 2:10.—Highly ornamental; once grown at Santa Monica, according to Kinney who says that the calyx-tube and stalk just before the lid falls become a brilliant crimson and are by far the most striking part of the fl.

21. *cosmophýlla*, F.v.M. Tall shrub or small tree: bark smooth, ash-colored: lvs. broad-lanceolate, 3-5 in. long, very thick and rigid: peduncles almost 0; lid hard, low-hemispheric, blunt or short-pointed; stamens 4-6 lines long; anthers ovate, opening by distinct parallel slits: fr. globose-truncate, not contracted at orifice, smooth, 7-8 lines across; rim thick. F.v.M. Eucal. 7:2.

22. *cordata*, Labill. Small tree, to 50 ft.: lvs. opposite, sessile, orbicular to ovate, somewhat crenate, rarely over 3 in. long, usually white-mealy, as also the infl.: calyx broadly campanulate, obtuse at base,

smooth; lid low-hemispherical, obtuse or with sharp tip, shorter than tube; stamens 3-4 lines long; anthers opening by parallel slits: fr. globular-truncate, hard, 4-6 lines thick; valves rarely protruding. F.v.M. Eucal. 8:1. B.M. 7835. G.C. III. 3:803; 30:456; 47:168.—Useful mainly as an ornamental.

23. *pulverulénta*, Sims. Lvs. always entire: calyx-tube turbinate, tapering to the base; lid variable, mostly conical; otherwise about as in *E. cordata*. F.v.M. Eucal. 8:7. B.M. 2087. Gn. 75, p. 140.—The very blue foliage supplies a pleasing contrast for ornamental planting.

24. *cornúta*, Labill. YATE TREE. Moderate-sized or large tree, usually low-branched and spreading: bark either deciduous in irregular sheets or persistent and rough: lvs. oblong or broad-lanceolate, often obtuse, 2-5 in. long: fls. greenish yellow, numerous, in dense heads; lid cylindric, horn-like, 1-1½ in. long; stamens 1½-2 in. long: fr. short-cylindric, 4-5 lines wide, valves much exerted and connivent into a beak-like projection. June-Oct. F.v.M. Eucal. 9:1. B.M. 6140 (lid too highly colored).—Used successfully as a roadside tree in S. Calif.: especially good as a shade tree: adapted to the lemon belt, and tolerating alkaline and saline soils (Franceschi). Timber hard, heavy, tough, and elastic.

25. *Léhmännii*, Preiss (*E. cornúta* var. *symphiocárpa*, Auct. *E. macrocéra*, Turcz.). Perhaps only a form of *E. cornúta*: lvs. more often short and obtuse: fr. half immersed in the receptacle, forming a solid woody mass. June-Oct.

26. *plátypus*, Hook. (*E. obcordata*, Turcz.). Tall shrub or small tree: bark smooth, grayish: lvs. petioled, oval to obcordate, very obtuse, 1-2½ in. long, leathery and shining: peduncles winged, recurved; fls. dull red or yellowish white, not conspicuous; lid conic-cylindric, much narrower than the prominently angled calyx-tube; stamens  $\frac{1}{2}$ -¾ in. long: fr. truncate-ovate, very angular, 4-7 lines thick. F.v.M. Eucal. 7:6. Hook. Icon. 849.

27. *occidentális*, Endl. FLAT-TOPPED YATE. Spreading shrub or medium-sized tree: bark deciduous, smooth, or somewhat persistent and rough: lvs. lanceolate, acuminate, 1½-5 in. long; lid cylindric-conic,  $\frac{1}{2}$ -¾ in. long; stamens yellowish or orange,  $\frac{1}{2}$ -¾ in. long: fr. bell-shaped, with spreading rim, 5 lines wide; valves exerted, sharp. Oct.-May. F.v.M. Eucal. 6:5.—Suited to the coast districts; subject to frost.

28. *coccífera*, Hook. Small glaucous tree with smooth white bark: lvs. lanceolate, thick and shining, often tipped by a slender curved mucro: fls. nearly sessile, in close terminal clusters; calyx prominently angled; lid very short and flat, rugose; stamens about 3 lines long, all perfect; anthers reniform, opening by divergent slits: fr. obovoid-truncate, 4-6 lines across. B.M. 4637. G.C. II. 12:113; 13:395; III. 2:787, 789; 3:799, 801; 9:169. Gn. 71 p. 591. Maiden, Crit. Rev. Eucal. 28 (figs. 3-5).—A high-mountain form compared by some to *E. amygdalina* but recognized by the depressed lid and longer calyx. Of value as an ornamental: a very hardy species suitable for the foothill districts.

29. *virgáta*, Sieb. Shrub or small tree with stringy bark: lvs. lanceolate, thick and shining: calyx not angled; lid conical, granular-roughened, as also the tube; stamens scarcely 2 lines long; anthers reniform, opening by pores which extend into oblong slits: fr. globose-truncate, smooth, 3-6 lines across. Maiden, Crit. Rev. Eucal. 43 (figs. 1, 2).

Var. *stricta*, Maiden (*E. stricta*, Sieb.). Lvs. linear or linear-lanceolate: lid often shortly pointed. Maiden, Crit. Rev. Eucal. 43 (figs. 12-17). F.v.M. Eucal. 10:9. B.M. 7074.

1427. *Eucalyptus globulus*. No. 18.

Var. *obtusiflora*, Maiden (*E. obtusiflora*, DC.). Lvs. rather broad; lid depressed-hemispheric, very obtuse. Maiden, Crit. Rev. Eucal. 43 (figs. 3-11).

30. *hæmastoma*, Smith. Large tree: bark smooth, mottled, with a few ribbony flakes near the butt: lvs. lanceolate, usually oblique at base, falcate, coriaceous: fls. pedicelled, clavate in bud; lid very short; stamens 2-3 lines long; anthers of the perfect ones reniform, opening by short divergent slits: fr. ovate-truncate, with reddish rim, 3-4 lines across; valves sometimes slightly protruding, but soon deciduous. F.v.M. Eucal. 2:3. Maiden, Crit. Rev. Eucal. 46 (figs. 10-17), 47 (figs. 1-18).—Said to thrive on poor, sandy soil: perhaps not suited to dry interior valleys. Timber of inferior quality.

31. *Sieberiana*, F. v. M. Scarcely distinguishable from *E. hæmastoma* save by the bark, which on the trunk is furrowed, becoming dark, rugged, and stringy: foliage emits a slight peppermint-like odor when crushed in the warm hand. F.v.M. Eucal. 2:9. Maiden, Crit. Rev. Eucal. 45 (figs. 10-15).—Bark yields a very soluble kino.

32. *goniocalyx*, F. v. M. MOUNTAIN GUM. BASTARD BOX TREE. Tall tree: bark rough, tardily deciduous: lvs. lanceolate, usually falcate, of pale color: pedicels very short and angular, or fls. usually sessile; lid conical or hemispherical; stamens about 3 lines long, inflexed in bud; anthers ovate, opening by parallel slits: fr. ovoid-truncate, 3-4 lines across; valves about on a level with the rim. July, Aug. F.v.M. Eucal. 1:3. Maiden, For. Fl. N.S.W. 19.—Timber especially esteemed for wheelwrights' work: also used for house-building, fence-rails, railroad-ties, and so on: excellent for fuel. Grows well in the coast districts of S. Calif. A promising species for the mountains of the S. W., at moderate altitudes.

33. *Cambagei*, Deane & Maiden. BUNDY. Small or medium-sized tree: bark fibrous and matted throughout: lvs. lanceolate, elongated: fls. sessile; calyx-tube with 2-4 prominent angles; lid shortly pointed or hemispherical; stamens about 3 lines long; fr. ovoid-truncate. —A recently intro. species related to *E. goniocalyx* but with plainly exserted valves and thicker, flatter peduncles. Aside from shape of buds and peduncles it resembles *E. Stuartiana*.

34. *botryoides*, Smith. Tall handsome tree: bark rough, furrowed, persistent on trunks: lvs. lanceolate, acuminate with very diverging parallel veins, paler beneath: fls. sessile or nearly so; lid variable; stamens about 3 lines long, inflexed in the bud; anthers ovoid-oblong, with parallel cells: fr. obovoid-oblong, slightly contracted at orifice, 4-5 lines long, 3-4 lines wide; valves wholly inclosed. Sept., Oct. F.v.M. Eucal. 4:2.—This tree has beautiful dark green horizontal foliage. Useful for windbreaks and as a shade tree. Suited to the coast districts only. Timber hard, tough, and durable; used in Austral. especially for felloes.

35. *robusta*, Smith. SWAMP MAHOGANY. Handsome symmetrically branched tree of moderate height: bark of trunk persistent, rough, dark brown; of the branches reddish: lvs. oval-lanceolate, long-pointed, 3-7 in. long, 1½-3 in. wide, dark green, coriaceous; veins spreading almost at right angles to midrib; lid acute, about as long as calyx-tube; stamens 4-6 lines long; anthers with parallel cells: fr. goblet-shaped, becoming nearly ½ in. across, the rim thin and caps. much sunk. Oct.-March. F.v.M. Eucal. 7:8.—Formerly much planted in Calif. as a street tree, but the tops break down in strong winds, due to the heavy foliage and brittle wood; now almost discarded for this purpose: a profuse bloomer, especially valuable for bees: wood brittle but durable. Best adapted to moist coast districts but also flourishes in the interior valleys when given sufficient water: suggested for the coast

of the Gulf of Mexico in districts free from heavy frosts.

36. *redunca*, Schau. Shrub or small tree, to 120 ft.: bark smooth, white: lvs. oblong-lanceolate, rather obtuse, 3 in. or less long, not paler beneath: lid conical, acuminate, about twice as long as calyx-tube; stamens 3-4 lines long; anthers opening by parallel slits: fr. obovoid, about 3 lines thick. F.v.M. Eucal. 10:7.—Grows on cold flats of comparatively poor soil in Austral. Timber tough, heavy, and durable; prized for wheelwrights' work.

37. *pilularis*, Smith. BLACKBUTT. Slender tree, averaging 100-150 ft.: bark of trunk persistent, or flaking off above, blackish gray outside, somewhat fibrous and brownish inside; of branches smooth, gray or whitish: lvs. mostly lanceolate, falcate, acuminate, 3-6 in. long, rather less shining below than above; lid broadly conical at base, attenuate; stamens 2-3 lines long; anthers reniform, opening by divergent slits: fr. subglobose, truncate, 4-5 lines thick; valves completely inclosed to slightly exserted. F.v.M. Eucal. 3:7. Maiden, Crit. Rev. Eucal. 1, 3, 4.—Timber strong and durable: useful for general building and especially for telegraph poles, posts, and the like: reported as a good honey-producer. Does not thrive in the hot dry interior valleys: subject to extremes of temperature.

38. *Muelleriana*, Howitt. YELLOW STRINGYBARK. Perhaps only a var. of *E. pilularis*: bark more fibrous or stringy, the inner bark yellow and imparting a yellow stain to the wood: juvenile lvs. often with tufts of hairs; adult lvs. glossy above: lid blunt or slightly pointed: fr. typically 6 lines thick. Maiden, Crit. Rev. Eucal. 2, 38 (in part).—Forms with scarcely flattened peduncles approach *E. eugenioides*.

39. *acmenioides*, Schau. (*E. triantha*, Linn. *E. pilularis* var. *acmenioides*, Benth.). WHITE MAHOGANY GUM. Tall tree: bark persistent and fibrous on trunk and branches: lvs. paler beneath, sinuate: peduncles not much compressed, slender; pedicels sometimes 2 or 3 lines long: fr. not exceeding 3 or 4 lines in diam.; rim thin: otherwise as in *E. pilularis*. F.v.M. Eucal. 10:1. Maiden, Crit. Rev. Eucal. 42.—Grows in poor, well-drained soil in Austral. Timber heavy, strong, and durable; good for palings, rails and floorboards.

40. *microcorys*, F. v. M. TALLOW-WOOD GUM. Tall tree: bark persistent, wrinkled: lvs. broadly lanceolate, acuminate, thin, copiously dotted with oil-glands, much paler and opaque beneath: fls. distinctly pedicelled, the buds club-shaped; lid depressed-hemispherical; stamens about 3 lines long, outer ones sterile; anthers minute, almost heart-shaped, opening by divergent slits: fr. scarcely 2 lines across. F.v.M. Eucal. 2:6. Maiden, Crit. Rev. Eucal. 41 (figs. 6-9).—Timber yellowish; one of the most valuable after ironbark: strong and durable, under or above ground; used by wheelwrights and for flooring, especially for ballrooms; suitable for this latter purpose because of its greasy nature.

41. *punctata*, DC. LEATHER-JACKET. HICKORY GUM. Beautiful spreading tree, 100 ft. or more high: bark smooth and dark, thick, the outer deciduous in flakes: lvs. thin, narrowly lanceolate, acuminate, lustrous above, slightly paler and marked with oil-dots beneath; lateral veins moderately spreading: peduncles broad, much compressed; pedicels evident, angular, thick; lid ovate-conical; stamens about 3 lines long; anthers opening by parallel slits: fr. 3 or 4 lines wide, not contracted at orifice; valves barely exserted. Aug.-Oct. F.v.M. Eucal. 6:7.—Timber remarkable for its extreme hardness and durability. Grown in S. Calif.; too tender for the San Joaquin Valley.

42. *saligna*, Smith. Tall tree: bark gray and smooth: lvs. lanceolate, with close parallel transverse veins

much paler beneath; pedicels very short or fls. usually sessile; lid hemispherical, short, pointed; stamens 2-3 lines long, all fertile; anthers ovate, opening by parallel slits; fr. subglobose-truncate, not contracted at orifice; rim narrow; valves more or less protruding, separated from the rim by a narrow groove. F.v.M. Eucal. 2:8. Maiden, For. Fl. N.S.W. 13.—Timber of the best, usually pale red, straight-grained, comparatively easy to work. Prefers rich alluvial soil; probably will not endure severe conditions.

43. *resinifera*, Smith. KINO EUCALYPT. RED MAHOGANY. Erect symmetrical tree; bark of trunk persistent, rough, and fibrous; of branches deciduous; lvs. lanceolate, thick, and almost leathery; oil-dots quite obscure; veins widely spreading from midrib; lid conical; stamens 4-6 lines long; anthers ovate, opening by parallel slits; fr. about 4 lines wide, not contracted at orifice; valves acute, well exerted. F.v.M. Eucal. 1:9.—Apparently endures both cold and drought better than *E. globulus*; requires a rather moist climate. Wood strong and durable, red, but bears no real resemblance to true mahogany; not liable to shrink; lasts well underground.

Var. *grandiflora*, Benth. Fls. larger, the ovoid buds about 4 lines diam.: fr. 4-6 lines wide, with a raised rim.

1428. *Eucalyptus corynocalyx*. ( $\times \frac{1}{2}$ ) No. 60.

44. *piperita*, Smith. PEPPERMINT STRINGYBARK. Tall tree; bark of the trunk persistent, gray, rough and fibrous; of the branches smooth: lvs. oblique, 2-6 in. long, thin; veins very oblique but obscure; oil-dots copious, transparent; lid broad-conical, acute, about as long as calyx-tube; stamens about 2 lines long; anthers kidney-shaped, opening by divergent slits; fr. globular, ovoid, or urceolate, contracted at orifice,  $\frac{1}{4}$  in. across; rim thin, depressed. F.v.M. Eucal. 3:8. Maiden, Crit. Rev. Eucal. 45 (figs. 1-9).—The young foliage emits a strong odor of peppermint when bruised.

45. *eugenioides*, Sieb. Closely related to *E. piperita* but seedlings rough-pubescent: lvs. thicker, with more divergent veins and not peppermint-scented; bark strongly fibrous even on the small branches; rim of fr. flat or raised. July, Aug. F.v.M. Eucal. 3:8. Maiden, Crit. Rev. Eucal. 39 (figs. 1, 2), 40 (figs. 2-22).

46. *incrassata*, Labill. Shrub or small tree, to 25 ft.: lvs. lanceolate or ovate-lanceolate, rather obtuse, mostly 2-4 in. long; veins inconspicuous; calyx-tube ribbed in the common forms; lid thick, hemispheric or short-conic, often abruptly beaked; stamens all in-

flected in the bud; anthers ovate-oblong, opening by parallel slits; fr. ovoid-cylindric, about  $\frac{3}{4}$  in. across; valves often slightly exerted. F.v.M. Eucal. 5:6. Maiden, Crit. Rev. Eucal. 13, 15.—Australian deserts; one of the "mallee."

Var. *angulosa*, Benth. (*E. angulosa*, Schau.). Calyx-tube and lid prominently angled or ribbed, but varying much in this respect as well as in size of fls. and frs. Maiden, Crit. Rev. Eucal. 14.

47. *Planchoniana*, F. v. M. Tree, to 100 ft., with angular branchlets: lvs. lanceolate, acuminate, elongated; lid conical, about as long as the tube, both longitudinally streaked; outer stamens flexuous in bud but only the inner ones incurved; anthers broadly ovate, opening by parallel slits; fr. ovoid-cylindric, truncate, about  $\frac{3}{4}$  in. across, the caps. sunk and valves well inclosed. F.v.M. Eucal. 4:6.—A profuse bloomer. Timber heavy, hard, and durable; well adapted for sawing but not easily split.

48. *megacarpa*, F. v. M. Tree, 100 ft. or less high: bark deciduous, smooth, grayish white: lvs. lanceolate, falcate, mostly 4-6 in. long; fls. only 1-3 and sessile in the umbels; lid shortly conical; stamens about  $\frac{1}{2}$  in. long; anthers ovate-oblong, opening by parallel slits; fr. depressed-globular, thick and hard,  $\frac{3}{4}$ -1 in. across; rim convex, continuous with the thick obtuse incurved valves. F.v.M. Eucal. 6:3. Maiden Crit. Rev. Eucal. 78 (figs. 4-8).

49. *gomphocéphala*, DC. TOOART TREE. Tree, 120 ft. or less high: bark persistent, rough but not stringy, becoming dark: lvs. thick, narrowly acuminate, pale green: fls. usually 3-5, sessile; lid globose, very hard and thick; stamens 3-4 lines long; anthers opening by parallel slits; fr. turbinate; rim broad and convex, rounded to the incurved valves. F.v.M. Eucal. 7:4.—Easily distinguishable by the broad lid. Wood of a pale yellowish color; remarkable for hardness and strength, heavy, the grain close and twisted; shrinks but little and does not check while seasoning; suitable for large scantlings and for use where exposed to great heat, as in engine-rooms: one of the strongest woods known. Grows both along the coast and in the dry interior valleys: one of the most alkali-resistant species.

50. *ridis*, Endl. DESERT GUM. Tree, 100 ft. or less: bark gray, persistent, rough, but not deeply furrowed: lvs. broadly to narrowly lanceolate, mostly  $\frac{3}{4}$ -2 $\frac{1}{2}$  in. wide; peduncles  $\frac{1}{3}$ -1 in. long; pedicels short; lid conical, not beaked, about as long as calyx-tube; stamens 3-4 lines long; anthers opening by parallel slits; fr. broadly turbinate, 4-5 lines across; rim only slightly ascending. F.v.M. Eucal. 10:8.—Stands drought and extremes of temperature better than most other species: endures minimum temperatures of 15-18°: suitable for most situations in the S. W.: successfully used as an avenue tree and for windbreaks at Fresno, Calif. Timber probably of value only for posts and for fuel.

51. *decipiens*, Endl. Straggly shrub, or tree to 70 ft.: bark rough, persistent, fragile: lvs. ovate to lanceolate, 2 $\frac{1}{4}$ -4 $\frac{1}{2}$  in. long, seldom over  $\frac{3}{4}$  in. wide; peduncles  $\frac{1}{4}$ - $\frac{1}{2}$  in. long; pedicels 0; lid conical, often twice as long as calyx-tube; anthers very small, globular, opening by pores which become longitudinal slits; fr. broadly turbinate or globose, 3-4 lines across; valves awl-shaped. F.v.M. Eucal. 10:3. Maiden, Crit. Rev. Eucal. 63 (figs. 1-12).

52. *viminalis*, Labill. MANNA GUM. Plate XXXIX. Graceful tree, to 300 ft., the branchlets pendulous: bark either persistent, roughish, and dark-colored (never fibrous), or deciduous, very smooth, and grayish white: seedling lvs. lanceolate; mature lvs. lanceolate, acuminate, somewhat falcate: fls. usually 3, rarely 6-8, sessile or on very short pedicels; lid semi-ovate, mostly short-pointed; stamens about 3 lines

long; anthers ovate, opening by parallel slits: fr. subglobose-truncate, 3-5 lines across; rim flat or rounded; valves triangular, acute. May-Aug. F.v.M. Eucal. 10:10. G.C. III. 4:597.—A hardy species, grown as far north as Chico, Calif.: ranks next to *E. globulus* in rapidity of growth. Timber not so strong as that of many other sorts but of average value for fuel, and can be grown under conditions in which more valuable species would not survive or would make only an inferior growth. A good bee tree.

53. *Stuartiana*, F. v. M. APPLE-SCENTED GUM. Tall branching tree, with dense drooping foliage: closely related to *E. viminalis*, and distinguishable from the latter, when this has more than 3 fls. in an umbel, by the fibrous bark, roundish seedling lvs. and somewhat smaller fls.: pedicels almost 0; buds angular; lid almost hemispherical, or shortly and bluntly conical. Feb.-May. F.v.M. Eucal. 4:9.

54. *Macarthurii*, Deane & Maiden. Bark rough, "very woolly:" seedling lvs. linear-lanceolate, slightly cordate, strictly opposite; mature lvs. narrow, lanceolate: fls. 4-8, distinctly pedicelled; buds ovoid, smooth, very small: fr. semi-ovate, scarcely 3 lines across.—Related to *E. viminalis* and to *E. Stuartiana*: distinguished from the latter by the smooth slender-pedicelled buds and from both by the smaller fls. and frs.

55. *amygdalina*, Labill. PEPPERMINT GUM. Tree, the tallest of the genus (var. *regnans*): bark persistent on trunk and lower branches, fibrous: lvs. lanceolate, not noticeably oblique at base, 2-4 in. long; veins oblique; oil-dots large, not very numerous: fls. many and crowded in the umbels; buds clavate, often rough; lid hemispherical, very obtuse, shorter than the calyx-tube; stamens under 2 lines long; anthers kidney-shaped, opening by divergent slits: fr. hemispheric or shortly ovate, truncate, about  $\frac{1}{4}$  in. across; rim flat or slightly concave; valves flat or slightly protruding. F.v.M. Eucal. 5:1. B.M. 3260. B.R. 947 (as *E. longifolia*). G.C. III. 6:16. R.H. 1902, p. 83.—Timber of inferior durability and strength. Foliage with odor of peppermint; far richer in oil than any other eucalypt.

Var. *numerosa*, Maiden (*E. Andreana*, Naudin). Fls. very numerous, often over 20 in the umbel.

Var. *regnans*, F. v. M. (*E. regnans*, F. v. M.). GIANT GUM. Very tall tree (325 ft. or less high): bark usually smooth, whitish, fibrous only near the base: lvs. large, broad-lanceolate, especially those on seedlings broader than in typical *E. amygdalina*; oil-dots very fine, numerous: fr. usually conoid. Maiden, Crit. Rev. Eucal. 33.—Earlier reports of 400-500 ft. for this tree were erroneous (see Melbourne Argus for March 23, 1904, Maiden, Crit. Rev. Eucal. p. 183, and G.C. III. 47, p. 69).

Var. *angustifolia*, F. v. M. (*E. linearis*, Dehnh.). Graceful, spreading tree: branchlets drooping: lvs. very narrow: fls. numerous in the umbel. Jan.-Apr., and more or less throughout the year. Maiden, Crit. Rev. Eucal. 30 (fig. 5).

56. *Risdonii*, Hook. f. A beautiful glaucous-foliaged tree 20-50 ft. high, the branches somewhat pendulous: bark flaking off, smooth, not fibrous: early lvs. cordate, connate in pairs; later lvs. either opposite and ovate or alternate and broadly lanceolate, not very oblique at base; veins oblique: buds, fls., and fr. as in *E. amygdalina* but slightly larger. Maiden, Crit. Rev. Eucal. 32 (fig. 1).—A valuable ornamental: all the lvs. commonly opposite and connate.

57. *obliqua*, L'Her. (*E. fissilis*, F. v. M.). Tall tree: bark persistent even on the branches, grayish, very stringy but rather soft and fragile: lvs. thick, very oblique at base, 4-6 in. long; veins very oblique: lid hemispherical, depressed or somewhat pointed, shorter than the tube; stamens fully 3 lines long, opening by

diverging slits: fr. somewhat pear-shaped, truncate, slightly contracted at orifice,  $\frac{1}{4}$ - $\frac{1}{2}$  in. across; rim broad and concave: caps. well sunk. March-Aug. F.v.M. Eucal. 3:5. Maiden, Crit. Rev. Eucal. 5-8.—Will grow on poor soil but does not endure severe drought. Much valued in Austral. for bees: wood used only for cheap, rough work.

58. *stellulata*, Sieb. Small tree: bark becoming black and furrowed, deciduous in layers, smooth above: lvs. elliptic or lanceolate, 2-4 in. long; principal veins almost parallel to the midrib: fls. very small, numerous; buds ovoid, in star-like nearly sessile umbels; lid conic, acute, about equaling the tube; stamens under 2 lines long; anthers reniform, opening by divergent slits: fr. nearly globose, about 2 lines thick. F. v.M. Eucal. 6:9. Maiden, Crit. Rev. Eucal. 25.—Timber of but little value; scarcely used except for fuel.

59. *coriacea*, A. Cunn. (*E. pauciflora*, Sieb.). Tree, often tall, with spreading branches and slender somewhat pendulous twigs: outer bark deciduous; inner bark smooth, pale gray: lvs. ovate-lanceolate or lanceolate, 4-8 in. long, thick, smooth; lateral veins almost parallel to the midrib: fls. 5-10; buds club-shaped; umbels distinctly peduncled; lid hemispheric, obtuse or with a short point, twice or thrice shorter than the tube; stamens 2-3 lines long; anthers reniform, opening by divergent slits: fr. pear-shaped, truncate, 3-4 lines thick. Nov.-Feb. F.v.M. Eucal. 3:6 (as *E. pauciflora*). Maiden, Crit. Rev. Eucal. 26, 27, 28 (figs. 1, 2).—A high-mountain tree and one of the hardiest species. Cattle browse on the foliage in seasons of drought: timber used for fuel and fences; warps badly. Trees sometimes badly affected with scale.

60. *corynocalyx*, F. v. M. SUGAR GUM. Fig. 1428. Tree, to 120 ft.: bark smooth: lvs. elongate-lanceolate; veins oblique: lid almost hemispheric, projecting beyond the calyx-tube; stamens 2-3 lines long; anthers short-oblong, opening by distinct parallel slits: fr. almost egg-shaped, nearly  $\frac{1}{2}$  in. long by 3-4 lines thick; rim thin; caps. deeply sunk. June-Nov. F.v.M. Eucal. 2:2. G.C. II. 12:593.—A valuable drought-resistant species but does not endure temperatures below 20-25°. Timber close-grained and hard, of a yellowish white color: very durable underground: grown in Calif. for railway ties. An ornamental tree used for roadside planting in S. Calif.: affords much bee pasturage.

61. *buprestium*, F. v. M. Shrub, to 20 ft.: lvs. narrow, acute, 2-3 in. long: lid hemispherical, obtuse, shorter than calyx-tube; stamens 2-3 lines long; anthers opening by short divergent slits: fr. nearly globular, the orifice much contracted,  $\frac{3}{4}$ -1 in. across; rim depressed. July-Oct. F.v.M. Eucal. 6:1.—Valuable for bees.

62. *diversicolor*, F. v. M. (*E. collösea*, F. v. M. *E. diversicolor* var. *collösea*, Hort.). KARRI. Fig. 1429. Very tall symmetric tree: bark smooth, white: lvs. dark green and shining above; veins very diverging: lid obtusely conical, not wider than calyx-tube; stamens 4 lines long; anthers ovate, opening by parallel slits: fr. ovoid-truncate, about  $\frac{1}{2}$  in. long by 4-5 lines thick;

rim rather thick; caps. deeply sunk. Feb.-May, and again in Nov. F.v.M. Eucal. 5:4.—Thrives near the coast but does not endure well the dry heat of the interior: too tender for the San Joaquin Valley. A rapid grower, profuse bloomer, and considered a good tree for bees. Timber very hard, durable, of a light red color, and takes a fine polish: suitable for furniture, wagon work, ties, and general construction.

63. *salmonophlōia*, F. v. M. Finally tall: lvs. narrowly lanceolate, 2-5 in. long, shining; oil-dots copious: lid broadly conical, slightly longer than the tube; anthers roundish, opening by parallel slits: fr. semi-ovate, narrowed at base, 2 lines thick; valves much exserted, long-pointed. F.v.M. Eucal. 9:6.

64. *rostrata*, Schlecht. RED GUM, Fig. 1430. Tree, to 200 ft.: bark of mature trunks dark gray, either smooth and deciduous or somewhat persistent near the base and then checking into thick scales or even furrowed; bark of seedlings and twigs reddish: lvs. narrowly lanceolate, acuminate, 4-6 in. or more long: calyx-tube hemispheric; lid usually hemispheric and provided with a narrowed point or beak, sometimes merely conical and not beaked, rarely over 3 lines long; stamens 2-4 lines long; anthers oblong, opening by parallel slits: fr. nearly globular, rarely above 3 lines thick; rim broad, prominent; valves entirely protruding, even before they open. April-July. F.v.M. Eucal. 4:7.—One of the most valuable species; next to the sugar gum and forest gray-gum perhaps the most drought-resistant; withstands frosts better than blue-gum; endures the intense heat of Imperial Valley, on the Colorado Desert; grows where the ground is inundated for a considerable time; makes a good growth in alkali soils, yet best results are secured only on good soil, especially if moist and with a clayey subsoil. A slow-growing species in regard to height, but one of the first in regard to diam.-growth (Ingham). Timber

1430. *Eucalyptus rostrata* ( $\times \frac{1}{2}$ ). No. 64.

very durable, both above and below ground: heavy, takes a good polish: light red to deep red in color: not so strong as sugar and blue-gums and trees more irregular in growth: suitable for railroad-ties, piles, fence-posts, and the like: difficult to work when dry, therefore scarcely suitable for furniture. Blossoms supply honey to bees.

65. *tereticornis*, Smith. FOREST GRAY GUM. FLOODED GUM. Bark and the general characters as in *E. rostrata*: lvs. rather broadly lanceolate: calyx-tube

turbinate; lid slenderly conical, acuminate, rarely abruptly beaked, 3-6 lines long, always much longer than the tube; stamens 3-6 lines long: fr. obovoid or nearly globular, 3-4 lines thick; rim very broad and prominent; valves protruding. April-July. F.v.M. Eucal. 9:8.—Closely related to *E. rostrata*; usually coarser, the lvs. broader, peduncles and pedicels stouter, and fr. larger; yet variable in all these characters. According to Ingham, this species has an erect habit of growth, while *E. rostrata* grows very crookedly. Withstands fully as wide a range in temperature, moisture, and soil conditions as does *E. rostrata*: timber similar but usually paler in color; more valuable because of its more regular growth. *E. amplifolia*, Naudin, known in Calif. as the "Cooper" or "round-leaf tereticornis," is a form with large roundish lvs. when young.

66. *macrorhyncha*, F. v. M. Tall tree: bark dark gray, furrowed and fibrous: lvs. lanceolate, acuminate, 3-5 in. long; lower ones broader, thick, and coriaceous; veins very oblique, prominent: calyx-tube turbinate, the edge forming a prominent ring with the conical lid; anthers reniform, opening by divergent slits: fr. depressed-globose, 4-6 lines thick; rim broad, convex. F.v.M. Eucal. 1:5. Maiden, Crit. Rev. Eucal. 39 (figs. 3-21).

67. *Gúnnii*, Hook. f. CIDER GUM. Small, often scrubby tree: lvs. thick, shining, less than 3 in. long: lid shining, hemispherical, short-pointed; stamens 2-3 lines long; anthers nearly oval, opening by parallel slits: fr. pear-shaped, truncate, 3-4 lines across; rim thin; valves sometimes slightly protruding. April-July. B.M. 7808. G.C. II. 19:437; III. 2:781; 11:787.—A very hardy species: cattle readily browse on the foliage, as it lacks the peculiarly pungent eucalyptus odor. Fls. only 3 in the typical form, but this apparently not cult. in Amer.

Var. *acervula*, Deane & Maiden. Buds and foliage often of a yellowish cast: fls. usually 4-8 in the umbel: fr.  $\frac{1}{4}$ - $\frac{1}{2}$  in. across. F.v.M. Eucal. 4:5 (main fig.).—The form commonly grown in Calif. Sapwood yellowish.

Var. *undulata*, Auct. (*E. undulata*, Luehm., not of F. v. M.). SWAMP GUM. Tall tree: lvs. longer (over 3 in.), often 2 in. broad, somewhat undulate or plane: fr. top-shaped.—Yields much nectar: flowers earlier than *E. viminalis*. Timber strong and useful.

Var. *montana*, Auct. A mountain form of *E. Gunnii*, the only species which withstands the climate of the east of England.

68. *melliodora*, Cunn. HONEY-SCENTED GUM. YELLOW BOX. Spreading tree with somewhat drooping habit, to 150 ft. high: bark somewhat persistent below, roughish, brownish gray without, yellowish within, flaking off above, leaving the branches smooth: lvs. narrow, acuminate, 3-5 in. long: fls. small, the calyx about 2 lines across; lid conic-hemispherical; stamens 2-3 lines long; outer ones sterile; anthers minute, truncate, opening by terminal pores or short slits: fr. distinctly stalked, truncate-globular, under 3 lines thick. Feb.-Aug. F.v.M. Eucal. 2:5. Maiden, Crit. Rev. Eucal. 61 (figs. 1-14).—Will grow on poor hillside soil but best growth is made in the valleys. Timber used in Austral. by wheelwrights and shipbuilders: makes excellent fuel: fls. particularly rich in nectar and much sought by bees.

69. *odorata*, Behr. (*E. cajuputea*, Miq.). Differs from *E. melliodora* chiefly in the more erect habit and fr. which is often nearly sessile, obconic, not or scarcely contracted at orifice. F.v.M. Eucal. 2:7. Maiden, Crit. Rev. Eucal. 51 (figs. 9-19).—Grown at Fresno, Calif.: may be of value for its oil.

70. *doratóxylon*, F. v. M. SPEAR-WOOD. Beautiful shrub or small tree: bark smooth, greenish white: lvs. all opposite or nearly so, narrowly lanceolate, acumi-

nate, mostly under 3 in. long; fls. 4-7 on each recurved nearly terete peduncle; lid terminating in a rather long beak; stamens 2-3 lines long; anthers ovate-oblong, opening by parallel slits; fr. ovoid, about 3 lines long, scarcely as wide. F.v.M. Eucal. 4:4. Maiden, Crit. Rev. Eucal. 70 (figs. 3-5).—Of ornamental value because of its slender, graceful habit.

71. *marginata*, Smith (*E. floribunda*, Hueg.). JARRAH. Tall tree under favorable conditions, often low; bark persistent and somewhat fibrous or flaking off in strips; lvs. lanceolate, 3-6 in. long; veins widely spreading; peduncles sometimes a little flattened; lid oblong-conical, longer than calyx-tube; stamens 3-4 lines long, all fertile, the outer not inflexed in bud; anthers cordate-reniform, opening by divergent slits; fr. subglobose, narrowed to the stalk;  $\frac{1}{2}$  in. or more thick, hard, and smooth. April, May. F.v.M. Eucal. 7:5.—Valuable hardwood tree requiring a warm climate: not yet a success in Amer. Timber easily worked, takes a fine polish, not attacked by teredo, almost incombustible; used in England for street-paving and in Austral. for piles, underground work, telegraph-poles, ties, flooring, shingles, and general construction.

72. *Baileyana*, F. v. M. Tall tree: bark persistent throughout, fibrous; foliage dense and shady; lid hemispheric; anthers cordate, opening by divergent slits; fr. globular-urnshaped, scarcely  $\frac{1}{2}$  in. thick, 3-celled. F.v.M. Eucal. 3:1.—A "stringybark:" will grow well on sandy soil. Timber very tough: suitable for tool-handles: little known.

73. *erythronema*, Turcz. (*E. conoidea*, Benth.). Small tree: bark rough, reddish: lvs. lanceolate, 1-3 in. long, thick and shining; veins very oblique, obscure; fls. 2-3, red, distinctly stalked in the usually recurved umbels; lid hemispheric, acute; stamens about  $\frac{1}{2}$  in. long, raised above the border of the calyx by the thick disk; anthers oblong, opening by longitudinal slits; fr. top-shaped, truncate, 4-6 lines across; rim raised above the calyx-border, showing externally as a smooth ring. Spring. F.v.M. Eucal. 8:2.—A highly ornamental species of recent intro.

74. *leucóxylon*, F. v. M. (*E. gracilipes*, Naudin). WHITE IRONBARK. Fig. 1431. Tall tree, usually branching below: bark mostly deciduous in irregular strips, smooth, pale; juvenile lvs. ovate-lanceolate, sessile; adult lvs. narrow-lanceolate, grayish or dull green: fls. 2-5, mostly 3, long-stalked, white or rarely pink; lid semi-ovate, pointed, about as long as calyx-tube; stamens very unequal, outer ones often  $\frac{1}{2}$  in. long and usually sterile; anthers truncate, opening by apical pores; stigma much dilated; fr. obovoid, truncate, scarcely contracted at orifice, 4-5 lines across; rim thick. Nov.-April. F.v.M. Eucal. 1:4. Maiden, Crit. Rev. Eucal. 56 (figs. 1-12). R.H. 1901, p. 500.—Grows best near the coast and where there is plenty of rain but will endure considerable drought and poor soil: withstands minimum temperatures of 15-20°. Valuable bee tree, yielding an excellent honey. Timber superior to that of almost any other eucalypt for certain purposes: hard and durable, pale brown or white: used in carpentry and wheelwrights' work; also for ax-handles, railroad-ties, and underground work. The form with pink fls. is highly ornamental. Var. *purpurea*, Hort., has bright purple fls.

75. *sideróxylon*, Cunn. (*E. leucóxylon* var. *sideróxylon*, Auct.). RED IRONBARK. Characters mostly as in *E. leucóxylon*: usually not branched below: bark persistent, rough, dark red or black: juvenile lvs. linear-lanceolate; adult lvs. green: fls. white or yellowish except in the vars. Maiden, Crit. Rev. Eucal. 55 (figs. 5-13).—Wood dark brown or reddish, otherwise similar to that of *E. leucóxylon* and climatic requirements the same.

Var. *rosea*, Hort. (*E. leucóxylon* var. *rosea*, Hort.). Lvs. green: fls. rose-colored. Dec.-June.—A handsome

form and profuse bloomer, distinguished from the pink form of *E. leucóxylon* by the rough dark-colored bark.

Var. *pállens*, Auct. (*E. leucóxylon* var. *pállens*, Benth. *E. leucóxylon* var. *pállida*, Hort.). Lvs. silvery gray, not very coriaceous: fls. red.—A profuse bloomer.

76. *longifolia*, Link & Otto. WOLLYBUTT. Medium-sized or

tall tree: bark of old trunks persistent, gray, rough or wrinkled, somewhat fibrous: lvs. elongated-lanceolate; fls. long-stalked; lid broadly conical, acute, pale; stamens fully  $\frac{1}{2}$  in. long, inflected in the bud, all perfect; anthers ovate-oblong, opening by parallel slits; stigma not dilated; fr. bell-shaped or turbinate, truncate, angular, about  $\frac{1}{2}$  in. thick; rim prominent, ascending. F.v.M. Eucal. 2:4.—Flowering almost continuously: valuable for bees.

*E. annulata*, Benth. Shrub or small tree with characters of *E. cornuta*, except as follows: lvs. narrow-lanceolate, acuminate; lid 6-8 lines long, usually incurved; fr. depressed-globose, 4-5 lines thick, the convex rim protruding as a thick rim.—*E. Bosistoëna*, F. v. M. Next to *E. pilularis* in the key but perhaps related to *E. melliodora*. Lvs. narrow-lanceolate, copiously dotted, of equal color on both sides; veins very divergent: fls. few and pedicelled in the umbels; peduncles somewhat compressed; lid fully as long as tube, narrow-hemispheric; fr. small, with narrow rim; valves inclosed. Maiden, Crit. Rev. Eucal. 49 (figs. 1-4).—*E. californica*, used by Abbot Kinney in his book entitled "Eucalyptus," has not been recognized by botanists: also listed as *E. occidentalis* var. *californica*, Kinney.—*E. cinerea*, F. v. M. Related to *E. viminalis*. Bark persistent, fibrous: lvs. oppsite, sessile, cordate, more or less white-mealy: fls. 3-7, pedicellate; fr. 3 lines thick, with protruding valves.—*E. dealbata*, A. Cunn. Small tree, near *E. viminalis*: lvs. glaucous, often broad and obtuse: fls. 3-6, small: fr. rim flat; valves protruding even before they open. Cult. in Cuba.—*E. Deanei*, Maiden. Very close to *E. saligna*; distinguished chiefly by its broad sucker lvs.—*E. Fald Bay* (?), Naudin, is a horticultural form either of *E. rostrata* or of *E. tereticornis*: branchlets pendulous.—*E. jugalis*, Naudin, is a cult. form not yet identified.—*E. Maidenii*, F.v.M. Appearance and bark of *E. goniocalyx* but peculiar warty buds and caps of *E. globulus*: branchlets quadrangular.—*E. McClachie*, Kinney, is a horticultural name for the large-fld. form of *E. Gunnii* var. *acervula*.—*E. miniata*, A. Cunn. Placed after *E. ficifolia* in the key: fls. sessile in simple umbels, brilliant orange-color: fr. truncate-ovate, nearly 2 in. long. F.v.M. Eucal. 6:4.—*E. Mortoniana*, Kinney, is a horticultural species probably referable to *E. Maidenii*. Maiden, Crit. Rev. Eucal. 79 (figs. 13-14); 80 (figs. 1-12).—*E. patens*, Benth. Next to *E. pilularis* in the key: peduncles only slightly flattened, bearing 3-7 fls.; lid hemispherical, short-pointed, about half as long as tube; fr. truncate-ovate, 5 lines wide; rim narrow; caps. sunk. F.v.M. Eucal. 9:5.—*E. phaeafolia*, listed by Richter in Calif. Exp. Sta. Bull. No. 217, p. 1011, is probably a misprint for *E. ficifolia*.—*E. pinnata*, a garden name. J. H. Maiden suggests that Californian specimens under this name may be *E. coccifera* (Crit. Rev. Eucal., p. 143).—*E. rubida*, Deane & Maiden. Characters of *E. viminalis*, but bark always smooth and white, often with reddish patches, and the sucker lvs. broad.—*E. uncinata*, Turcz. Near *E. decipiens* in the key and, like it, a shrub: bark deciduous, smooth: lvs. very light green, narrow, copiously dark-dotted; veins fine, widely divergent; filaments kinked; anthers opening by terminal pores: fr. 2-3 lines across; valves little if at all exerted. F.v.M. Eucal. 4:10. Maiden, Crit. Rev. Eucal. 62.—*E. urnigera*, Hook. f. Shapely tree with drooping branchlets and glaucous bluish foliage: bark smooth, pale brown: fls. 2-4 in. long, obtuse: fls. mostly 3 in each umbel; peduncles often recurved: fr. nearly globose but somewhat urn-shaped, 4-5 lines wide; caps. much sunk and valves inclosed. Maiden Crit. Rev. Eucal. 80 (figs. 13-15).

Other names offered in foreign catalogues are: *E. capitellata*, *E. considenana*, *E. delegatensis*, *E. divas*, *E. gonipho-cornuta*, *E. lozophleba*, *E. paludosa*, *E. Smithii*.

HARVEY MONROE HALL.

1431. *Eucalyptus leucóxylon* ( $\times \frac{1}{2}$ ). No. 74.

**EUCHARIDIUM** (from the Greek for *charming*). *Onagraceæ*. Pretty small annuals, one of which (*E. concinnum*) is well known in gardens.

Three Californian herbs allied to *Clarkia* (and often referred to it), but differing in the calyx-tube being much prolonged beyond the ovary, and the stamens 4 and opposite the sepals and not appendaged at the base; petals lobed. Cult. simple, as for *Clarkia*.

**concinnum**, Fisch. & Mey. (*Clarkia concinna*, Greene), is a graceful garden annual, growing 1-2 ft. high, simple or very nearly so, pubescent or glabrous: lvs. small, oblong, petioled, entire: fls. regular, rose-colored, nearly or quite an inch across; calyx-tube filiform, an inch or more long; filaments filiform; petals 3-lobed, the middle lobe not much exceeding the others. B.R. 1962. B.M. 3589.—Of easy cult. in any garden soil; a useful annual.

**grandiflorum**, Fisch. & Mey. (*Clarkia grandiflora*, Greene). Differs from above in being diffusely branched from the base, corolla larger, irregular, 3 upper petals approximate and the other separate and declined, all the middle lobes long-clawed. There is a var. *alba* advertised.

**Bréveri**, Gray (*Clarkia Bréveri*, Greene. *C. Szadna*, Greene). 1-2 ft. high: lvs. 1 in. or more long, lanceolate, entire, short-petioled: corolla irregular; petals broadly obovate with the middle lobe narrow-spatulate and much exceeding the other lobes; filaments club-shaped: has a honeysuckle fragrance. L. H. B.

**EÜCHARIS** (very graceful, from the Greek). *Amayllidaceæ*. AMAZON LILY. Hothouse bulbous plants of great beauty and delightful fragrance, blooming in late winter and spring and at other times if the requisite treatment is given.

Bulb tunicated, 1-2 in. diam.: lvs. broad-ovate, narrowed into distinct petioles, prominently parallel-ribbed, radical: fls. white, in umbels, very showy, standing on long stout scapes; perianth-tube straight or curved, the throat dilated; segms. broad and spreading; perianth-cup either entire or toothed between the filaments: ovules 2 to many in each of the 3 locules.—Six or 8 handsome species from Colombia. The species are confused.

*E. grandiflora* (known to gardeners as *E. amazonica*), *E. candida* and *E. subdentata* are the well-marked types. The fls. in Fig. 1432, adapted from authentic plates, will distinguish the types. Hybridizes with *Urceolina* (see *Urceocharis*).

The Amazon lilies, as *eucharis* are popularly called,

are among the most desirable of warmhouse bulbous plants, being not only very beautiful but also very free in the production of flowers. When grown in pots, they require a coarse fibrous soil, composed chiefly of rotted 3od, and enriched with about one-fourth of dry cow-manure and a sprinkling of bone-dust. The pots should be well drained, for much water is needed during the growing season, but frequent potting should be avoided as the roots are impatient of disturbance. Shading from full sunshine is required, except during the winter months, and a night temperature of 65° to 70° is best for these plants. By drying off the *eucharis* to some extent for a few weeks, a crop of flowers may be had at almost any season, providing the bulbs are strong and healthy, but they should never be dried to such a degree that all the foliage is lost, else the bulbs will be much weakened. Good results are also had from planting out the *eucharis* on a bench in a warmhouse, the soil and treatment being much the same as for pot-grown specimens. The only insects liable to give much trouble in connection with these plants are mealy-bugs and thrips, and these may be controlled by thorough syringing. (W. H. Taplin.)

**grandiflora**, Planch. (*E. amazonica*, Lind.). AMAZON LILY. STAR OF BETHLEHEM (a name also applied to *Ornithogalum*). Fig. 1432. Bulb globular, 2 in. diam.: lvs. 2-4 to each stem, the petiole about 12 in. long; lf.-blade 1 ft. or more long and 5-6 in. broad, oblong; scape 1-2½ ft., bearing an umbel of 3-3 large (4 in. across), very fragrant star-like fls. on pedicels nearly or quite 1 in. long; segms. spreading, oblong and obtuse; tube of perianth cylindrical and curved, 2 in. long; cup forming a distinct projecting tube. B.M. 4971. F.S. 9:957; 12:1216-17. Gn. 48, p. 217; 59, p. 25; 61, p. 125; 63, pp. 71, 131; 66, p. 412; 76, p. 67; 77, p. 418. G.C. III. 7:193; 16:665; 28:115; 35:117; 41:71; 51:141. R.H. 1912, p. 115. G. 3:407; 9:301 (*E. amazonica* var. *grandiflora*); 10:5. G.L. 21:476. G.M. 46:83. G.W. 2, p. 87. G.Z. 2:1. A.F. 5:363; 8:445. F.E. 8:1000. F.R. 1:11; 2:364. Var. **Moðrei**, Baker, has smaller, rounder and thicker lvs., and smaller fls. with the cup lined with yellow.—Of all warm greenhouse bulbous flowering plants, *E. grandiflora* (*E. amazonica* of the gardener) stands without a rival in the purity and beauty of its bloom.—Prop. by offsets, but one must always bear in mind that these plants do not like to be disturbed much at the roots, and it will be some time before they recover from the operation of being divided. The spring is the best time to separate the bulbs. Turn the plant out of its pot, and take a hose with a gentle pressure on it and wash all the loam carefully away from the roots, care being taken to break as few as possible.—It thrives well in a good turfy loam. Add about a third of dried cow-manure, with as much sand and charcoal to keep the whole porous. The pots should be well drained with crocks, as these plants will never do well if the soil gets into a "sour" condition. Three bulbs to a 6-inch pot are enough, but if large specimens are desired for exhibitions, increase the number and the size of pot, having in view what is desired. Do not give much water after plants are divided, until growth has begun. When they are growing vigorously, a copious supply of water is required. A temperature of 65° by night should be maintained, and during the day it may run to 80° or 85°. The air should never be allowed to become "stagnant." This applies, of course, to all kinds of plants grown in glass structures. It must be remembered that in their native place the plants grow outdoors, and in heating greenhouses allowance should be made for the free admission of fresh air at all times. *Eucharis* like a light shade over them during the brightest part of the day, but from about the end of Sept. until March they will stand all the sun possible. *E. grandiflora* can be flowered 2 or 3 times during the year.—When the lvs. are fully matured, cease watering until signs of flagging of the

1432. *Eucharis*. Leaf of *E. grandiflora*, and fls. of a, *E. subdentata*; b, *E. Sanderi*; c, *E. grandiflora*; d, *E. candida*.

foliage is noticed, then water again to freshen them up. Keep this treatment up for a month, that is alternately drying and watering. The temperature may be lowered 5° during this resting-period. Start the plants by giving them a thorough soaking of water, and raise the temperature again to not less than 65° by night. The fl.-sts. will soon appear, and they may be watered with manure water, as advised for *Dipladenia*, until they begin to open, when it should be withheld until they have finished flowering. When the fl.-sts. have all been removed, a new set of lvs. will be meanwhile pushing up, and they may be again fed as advised above, until they are fully developed; and again treat them in every way as before. All the insect pests are liable to thrive on *Eucharis*, and the plants may be fumigated as advised for other greenhouse plants. Red-spider may be kept down by the syringe. (George F. Stewart.)

**Mástersii**, Baker. Bulb globose, often smaller: fl.-blade 8–9 in. long and 4–5 in. broad, oblong, rounded at the base, exceeding the petiole: scape 1 ft. high, bearing 2 nearly sessile fls. (2½–3 in. across) in the umbel, the perianth-segms. ovate and spreading and shorter than in *E. grandiflora*; tube slightly curved, 2 in. long; cup forming a shallow frilled or notched collar. B.M. 6831. G.C. II. 24:721. G.Z. 31, p. 217.—Possibly a hybrid of *E. grandiflora* and *E. Sanderi*.

**cándida**, Planch. Fig. 1432 d. Bulb globose, bearing stolons 2 in. diam.: fl.-blade 9–15 in. long, 4–5 in. broad at the middle, oblong, gradually narrowed both ways, about as long as petiole: scape somewhat flattened, glaucous, 1–1½ ft. high, bearing 6–10 short-pedicelled fls. in an umbel; segms. oblong, acute, more or less reflexed; tube 1½–2 in. long, curved; winged yellow filaments projecting, united at the base only. F.S. 8:788. G. 6:5; 15:289. J.H. III. 61:443. G.Z. 21, p. 194.—Smaller-fl. than *E. grandiflora*.

**Sánderi**, Baker. Fig. 1432 b. Bulb ovoid, 1–2 in. diam.: fl.-blade 10–12 in. long and 5–6 in. broad, oblong, cordate at base, twice longer than petiole: scape terete, 1 ft., bearing 2–3 nearly sessile fls.; segms. ovate, 1 in. or more long; tube curved, 2 in. long; yellowish cup, very narrow, like a collar or rim, and bearing the short, curved filaments on its edge. B.M. 6676. G.C. II. 19:349. G. 6:277. J.H. III. 52:9. G.Z. 28, p. 145.—By some thought to be a hybrid of *E. grandiflora* and *E. cándida*. Var. **multiflora**, Baker. Fls. smaller, 4–6, striped green. B.M. 6831.

**subdentata**, Benth. (*Calliphruria subdentata*, Baker). Fig. 1432 a. Bulb ovoid, 1½ in. diam.: fl.-blade 6–8 in. long, 3–4 in. broad, oblong, triangular at base, about as long as the channeled petiole: scape slender, 1 ft.; fls. 6–8 on pedicels 1 in. or less long; tube 1 in. long, funnel-shaped above; segms. oblong, ascending, 1 in. long; cup wanting or represented only by obscure teeth on the filaments. B.M. 6289. I.H. 28:415.—A small-fl. species.

*E. Bakeriana*, N. E. Br. Has the perianth of *E. grandiflora* and stamens of *E. cándida*: fls. 4–6 in the umbel, 2½ in. across, pure white; tube not enlarging emphatically at the top; cup projecting from the bases of the segms., not toothed: lvs. 4 or 5, elliptic, 10–18 in. long, very dark green and closely striate: scape 12–18 in. B.M. 7144. G.C. II. 7:417; 12:209.—*E. burfordensis*, Hort. Supposed hybrid between *E. Mastersii* and *E. Stevensii*: fls. bell-shaped, over 3 in. across, about 2 in. long.—*E. Elmétana*, Sander. Hybrid of *E. Sanderi* and *E. grandiflora*. Easier to grow than *E. Sanderi*. G.C. III. 26:345.—*E. Lehmannii*, Regel. Fls. about 4 in an umbel, 1½ in. across, the spreading corona with 12 long, narrow teeth, the perianth-segms. spreading or reflexed: lvs. 2, elliptic-oblong. Gt. 38:1300.—*E. Löwii*, Baker. Robust: fls. 4 in. across, the spreading outer segms. 1 in. wide and the 3 inner ones incurved: lvs. larger than those of *E. cándida*, long-stalked. Perhaps a natural hybrid of *E. grandiflora* and *E. Sanderi*. G.C. III. 13:539. J.H. III. 28:111; 43:276. Gn.W. 10:7.—*E. Stevensii*, N. E. Br. Free-flowering: fls. 3–3½ in. across about 7 in the umbel, pure white with yellow on the outside of the cup or corona: lvs. 12–14 in. long; very like *E. Sanderi*, and a garden hybrid of that species and *E. cándida*. J.H. III. 30:253. Gn. 46:128. G.C. III. 17:365.

L. H. B.

**EUCHLÆNA** (Greek *eu*, well, *chlaina*, covering). *Gramineæ*. Annual or perennial grasses, with stout stems, broad blades and monœcious inflorescence, occasionally grown in the South for forage and sometimes for ornament.

Staminate infl. in a tassel at the top, the pistillate in small ears in the axils of the lvs.; spikelets 1-fl.; pistillate spike slender, the several joints producing 1-seeded frs. trapezoidal in shape, the surface smooth and hard. The aspect is that of Indian corn (*Zea*) from which it differs in having free slender-jointed pistillate spikes that are not united into a cob.—Only one species is generally recognized, but there are probably others, all Mexican or Cent. American.

**mexicana**, Schrad. (*E. luxurians*, Dur. & Aschers. *Reana luxurians*, Dur.). **TEOSINTE**. Annual: sts. strongly cespitose, decumbent and spreading at base, erect above, 5–10 ft. or even more, leafy. Dept. Agric., Div. Agrost. 20:11.—Occasionally cult. for forage in the Gulf states. The seed rarely matures north of S. Fla. See Cyclo. Amer. Agric., Vol. II, pp. 638–9.

A. S. HITCHCOCK.

**EUCNIDE** (Greek-made word, referring to the sharp nettle-like hairs). *Loasacæ*. Several N. American annual or biennial herbs, by some authors referred to *Mentzelia*. Plants with stinging hairs: lvs. alternate or the lower ones opposite, cordate or ovate, more or less lobed: fls. yellow or white; calyx-tube oblong, the limb persistent, 5-lobed; petals 5, united at the base and inserted on the throat of the calyx; stamens numerous, the filaments filiform; ovary 1-loculed, bearing a 5-cleft style. **E. bartonioides**, Zucc. (*Mentzelia bartonioides*, Benth. and Hook.), is sometimes cult. It is a pretty summer-flowering annual, thriving in warm garden soil. Sts. about 1 ft., somewhat succulent, more or less decumbent, hispid-hairy: lvs. alternate, petioled, broad-ovate and toothed-lobed: fls. large, on long pedicels, opening in sunshine, the petals ovate-pointed, the numerous yellow hair-like stamens projecting and brush-like. Mex., New Mex., and Texas. B.M. 4491 (as *Microsperma bartonioides*). Gt. 5:320. L. H. B.

**EUCODONIA** is referred to *Achimenes*. *E. Ehrenbergii*, Hanst.—*A. lanata*, Hanst. (See p. 208, Vol. I). It is offered abroad. *E. nagelioides*, Hort.—*Eucodonopsis nagelioides*, Van Houtte, being a hybrid between *Eucodonia Ehrenbergii* and *Nagelia zebrina splendens*. Fls. single on the summits of the peduncles, declined, rose-purple. F.S. 16:1608. Var. *lilacinella*, Van Houtte, has large fls. white at the throat and striped and pointed with purple, and lilac-marbled on the limb. F.S. 18:1858–9.

**EUCOMIS** (Greek, *beautiful hair* or *topknot*). *Liliacæ*. Cape bulbs, half-hardy, producing radical rosettes of long leaves and a strong peduncle or scape bearing a raceme of greenish or whitish flowers more or less tinged with color, the cluster crowned or topped with a coma of leafy bracts (it is from this coma or crest that the generic name is taken).

Bulb tunicated: peduncle simple: lvs. lorate or oblong, often tinged or spotted with purple: fls. regular, 6-parted, rotate; stamens 6; ovary broad and short; style cylindrical and stigma capitate: caps. 3-valved.—Species about 12, African, nearly all from S. Afr. Prop. by offsets. The bulbs may remain in the open if in a warm place and well protected; some of them stand considerable frost, and bloom in spring. Of easy cult. Let the bulbs remain where planted. In the N. treated as glasshouse plants.

A. *Scape club-shaped*.

**règia**, Ait. Bulb globose, 2–3 in. diam.: lvs. 6–8, obtuse, not undulate toward the edge, to 1½ ft. long and 3–4 in. broad: scape 3–6 in. long, bearing a dense

oblong raceme 3-6 in. long; fls. green,  $\frac{1}{2}$  in. long, the segms. oblong, and stamens half as long as perianth: crown of 12-20 oblong, acute, crisped lvs. S. Afr.

**nana**, Ait. Bulb 2 in. diam.: lvs. about 8, obtuse, firm, purplish on back toward the base, to 2 ft. long, 3-4 in. broad above the middle; scape short, 1 in. thick at top, spotted purple; raceme with more or less purple, 3-4 in. long, dense, the fls. nearly sessile; perianth green,  $\frac{1}{2}$  in. long, the segms. oblong; crown of 12-20 oblong acute lvs. S. Afr.

**Jacquinii**, C. H. Wright. Differs from the above, with which it has been confused, in broader and shorter lvs. less tapering at base, and no purple in the infl. S. Afr.

AA. *Scape cylindrical.*

B. *Pedicels short.*

**undulata**, Ait. Bulb globose, 2-3 in. diam.: lvs. 6-9, strap-shaped, to  $1\frac{1}{2}$  ft. long, 2-3 in. broad, thin, not spotted on back, spreading or recurving, undulate; scape 1 ft. or less, bearing a dense raceme 3-6 in. long; perianth green,  $\frac{1}{2}$  in. long, the segms. oblong or oblanceolate; crown of 12-30 crisped lvs. S. Afr. B.M. 1083. G.W. 15, p. 305.

BB. *Pedicels long, erect-spreading.*

**punctata**, L'Her. PINEAPPLE FLOWER. Bulb globose, 2-3 in. diam.: lvs. 6-9, erect-spreading, long and narrow, to 2 ft. long and 2-3 in. broad, channeled, not undulate, brown-spotted beneath; scape 1 ft., spotted; raceme lax, cylindrical, to 1 ft. long; fls. green,  $\frac{1}{2}$  in. long, the ovary brown; crown of 12-20 oblong acute lvs. S. Afr. B.M. 913. F.S. 22:2307. G.W. 5, p. 121; 9, p. 5. J.H. III. 52:141. Gn. 70, p. 295. G. 19:291; 22:520; 27:409; 32:675. F.E. 31:1080.—A form with lvs. striped beneath with brown is var. *striata*, Sims. B.M. 1539.

**bicolor**, Baker. Bulb large and globose: lvs. 5-6, strap-shaped, thin, not spotted, undulate, to 2 ft. long by 3-4 in. broad; scape 1- $1\frac{1}{2}$  ft. long; raceme to 1 ft. long, dense at top; stamens and margins of perianth-segms. bright purple, otherwise close to *E. punctata*: crown of 12-20 oblong acute lvs. usually margined with red-purple. S. Afr. B.M. 6816. G.W. 14, p. 468. L. H. B.

**EUCOMMIA** (Greek, *eu*, well, and *kommí*, gum; alluding to the fact that the plant contains rubber). *Eucommia*ceæ. Deciduous tree grown for its handsome foliage and also for its possibility as a hardy rubber-producing tree.

Branches with laminate pith: winter-buds conspicuous, with imbricate scales: lvs. alternate, petioled, serrate, without stipules: fls. dioecious, without perianth, solitary in the axils of bracts at the base of the young shoots and precocious; staminate fls. pedicelled; stamens 6-10 with very short filaments and elongated linear anthers; pistillate fls. short-pedicelled with a 1-celled, 2-ovuled stipitate ovary, bifid at the apex, the lobes stigmatic on the inside: fr. a compressed winged nutlet.—One species in Cent. China, not closely related to any other genus; it was first placed with the Trochodendraceæ or Magnoliaceæ and afterward with the Hamamelidaceæ, but is now generally considered as representing a distinct family allied to the last named.

*Eucommia* is an upright-growing vigorous tree with rather large elliptic dark green foliage, inconspicuous precocious flowers and winged fruits; in habit and foliage it resembles somewhat an elm tree. In China the bark is a most valued medicine. The tree contains rubber in all its parts, particularly in the young growth and in the bark. Though the rubber has proved to be of good quality, it is apparently difficult of extraction and not present in sufficient quantity to make the commercial exploitation of the tree pay; therefore the hopes which have been set in this "hardy rubber tree"

will probably never realize. The tree has proved perfectly hardy as far north as Massachusetts and grows well in a loamy humid soil. Propagation is by seeds and by greenwood cuttings under glass.

**ulmoides**, Oliver. Tree, to 60 ft.: lvs. elliptic to elliptic-ovate, acuminate, broadly cuneate at the base, serrate, glabrous, glossy and dark green above, pubescent below when young, 3-7 in. long: samara oblong, bifid at the apex,  $1\frac{1}{4}$ - $1\frac{1}{2}$  in. long. April; fr. in Oct. Cent. China. H.I. 20:1950. R.H. 1909, p. 226. M.D.G. 1912:11, 613. ALFRED REHDER.

**EUCRYPHIA** (Greek for *well covered*). *Eucryphia*ceæ; formerly referred to *Rosaceæ*. A very few southern hemisphere resinous trees or shrubs, with opposite evergreen simple or pinnate lvs. and showy white fls.: sepals 4, free; petals 4, broad; stamens very many; ovary free, 5-18-celled: fr. a hard dehiscent caps. *E. pinnatifolia*, Gay, is a shrub or small tree, hardy in parts of England, with large white hypericum-like 4-petaled fls. and rose-like foliage, from Chile. B.M. 7067. G.C. II. 14:337; III. 9:613; 10:217; 15:109; 23:15 (fr.); 30:351. Gn. 63, p. 281; 77, p. 423. G. 29:96; 33:25. F.S.R. 1, p. 41. Gn.W. 9:821. G.M. 53:203. *E. cordifolia*, Cav., has simple serrate lvs. B.M. 8209. G. 33:607. G.C. III. 22:247; 42:259; 44:129. Gn. 70, p. 190; 73, p. 471.—Neither of these is in the American trade. Worthy of trial in the S. There are 2 species (*E. Billardieri*, Spach, and *E. Moorei*, Muell.) in Tasmania and New S. Wales.

Plants of *E. pinnatifolia* give much satisfaction in the open in England although not much known, the pure white fls. 3 in. diam., and borne more or less in pairs, being produced in great profusion in late summer; it grows 8-10 ft. high.

**EUGENIA** (named in honor of Prince Eugene of Savoy). *Myrtaceæ*. A large group of trees and shrubs, grown chiefly for their ornamental foliage and berries. Many tropical species yield edible fruits which are both eaten out of hand and made into jellies or confections. A number of these have been recently introduced into the warmer parts of the United States, where they give promise of attaining much importance. The clove of commerce belongs to this genus.

Evergreen trees and shrubs: lvs. opposite, mostly entire and finely penniveined: fls. white or creamy or the numerous stamens yellowish: fr. a drupe-like berry, usually globular or pear-shaped, 1-5-seeded. Habit and infl. of *Myrtus*, which see for cult. and prop.

INDEX.

aromatica, 8.	<i>Dombeyi</i> , 1.	microphylla, 4.
asperifolia, 4.	jambolana, 9.	myrtifolia, 5.
australis, 5.	jambos, 6.	Pitanga, 3.
brasilensis, 1.	macrophylla, 7.	uniflora, 2.
caryophyllata, 8.	malaccensis, 7.	vulgaris, 6.
Caryophyllus, 8.	Micheli, 2.	

A. *Fls. solitary on axillary peduncles; petals not united.* (*Eugenia proper*.)

1. **brasilensis**, Lam. (*E. Dombeyi*, Skeels). GRUMIX-AMEIRA of Brazil. Tree, to 50 ft., glabrous or the infl. obscurely puberulent: lvs. oval or obovate-oblong, tapering at base, obtuse,  $2\frac{1}{2}$ -5 in. long, 1- $2\frac{1}{2}$  in. broad: peduncles 1-2 in. long, much exceeding the scales which subtend them: fr. edible, scarlet, black at maturity, the size of a cherry. Brazil. B.M. 4526. R.H. 1845:425.—Cult. in S. Calif. The frs. are candied and eaten in the tropics.

2. **uniflora**, Linn., not Berg. (*E. Micheli*, Lam.). PITANGA. SURINAM CHERRY. Shrub, 5-20 ft., glabrous: lvs. ovate-lanceolate, obtuse at base, glossy, 1-2 in. long, exceeding the peduncles: berry  $\frac{1}{2}$ -1 in. diam., ribbed, resembling a miniature tomato, edible, with a spicy acid flavor. Trop. Brazil. R.H. 1889, p. 532.—Hardy in S. Fla. and in S. Calif. Much esteemed for

jellies. Useful also as a pot-plant, producing an abundance of showy red frs.

3. *Pitánga*, Kiaersk. PITANGA. Low shrub, young foliage and branchlets reddish pubescent: lvs. elliptic-oblong, acute at base,  $1\frac{1}{2}$ –3 in. long: berry red, subglobose, obscurely 8-nerved, about  $\frac{1}{2}$  in. diam. S. Brazil and adjacent Argentine.—Intro. into S. Calif. by Franceschi.

4. *microphylla*, A. Rich., not Bedd. nor Rich. ex Berger (*E. asperifolia*, Berg). Branchlets and infl. pilose: lvs. small, oval, acute, glabrous, longer than the peduncles: fr. unknown. Cuba.—Species other than the true *E. microphylla* apparently have been intro. under this name.

AA. Fls. in cymes or panicles; petals spreading, not united. (*Jambosa*, *Caryophyllus*.)

5. *myrtifolia*, Sims (*E. australis*, Wendl. *Jambosa myrtifolia*, Ndz.). AUSTRALIAN BRUSH CHERRY. Tree, attaining 80 ft., glabrous: lvs. oval or oblong-lanceo-

1433. Flower of rose-apple, *Eugenia Jambos*. (Natural size.)

late, mostly acute,  $1\frac{1}{2}$ –3 in. long: fls. white: fr. red, ovoid, nearly 1 in. long, with an acid taste. Austral. B.M. 2230. Univ. Calif. Pub. Bot. 4:8.—Hardy in the S. Much used in Calif. as an ornamental tree and for clipped hedges. The foliage is dense and glossy, green when mature, tinged with wine-red on the gracefully spreading young shoots. Frs. sometimes used in jelly-making.

6. *Jámbos*, Linn. (*Jambosa vulgaris*, DC. *Jambosa Jámbos*, Millsp.). ROSE-APPLE. JAMROSADE. JAMBOS. Fig. 1433. Tree, 20–30 ft., glabrous: lvs. lanceolate, very acuminate, 5–8 in. long, 1–2 in. broad, thick and shining: fls. greenish white: fr. pyriform,  $1\frac{1}{2}$ –2 in. thick, white or yellowish, tinged with rose-color, edible but rather insipid, fragrant. E. Indies. B.M. 1696. Gn. 75, p. 616.—Hardy in Calif. as far north as San Francisco. Grown for its rich foliage and showy fls. Frs. much used in the tropics for jelly-making and in confectionery.

7. *malaccensis*, Linn. (*E. macrophylla*, Lam., not Berg. *Jambosa malaccensis*, DC.). LARGE-FRUITED ROSE APPLE. JAMBOS. Glabrous tree: lvs. oblong to elliptic, acute, 5–10 in. long, 2–4 in. wide: fls. purple: fr. fragrant, red, obovoid, about 2 in. diam., with apple-like flavor. Polynesia.—More tender than *E. Jambos*, but the foliage more luxuriant and the frs. larger.

8. *aromática*, Baill., not Berg (*Caryophyllus aromáticus*, Linn. *E. caryophyllata*, Thunb. *Jambosa Caryophyllus*, Ndz.). CLOVE TREE. Lvs. ovate-oblong, acute, strongly tapering to the conspicuous petiole, 2–5 in. long, coriaceous, dotted; lateral veins numerous, parallel, the cross-veinlets obscure: fls. in terminal trichotomous cymes, pale purple, only  $\frac{1}{4}$  in. across. Moluccas.—Widely cult. in the tropics. Apparently not suited to even the warmer parts of U. S. The fls. are the cloves of commerce. See *Cloves*.

AAA. Fls. in cymes or panicles; petals united into a calyptra. (*Syzygium*.)

9. *jambolana*, Lam. (*Syzygium jambolana*, DC.). JAMBOLAN, or JAMBOLAN PLUM. Tall shrub or tree: lvs. broadly oblong, very broad at summit but often shortly apiculate,  $2\frac{1}{2}$ –5 in. long,  $1\frac{3}{4}$ –4 in. wide, thick and shining: berry edible, varying from the size of a cherry to that of a pigeon's egg. E. Indies.—Grown at Santa Barbara, Calif., where, according to Franceschi, the trees become large and flower profusely but never ripen fr.

*E. alba*, Roxbg., Malaya, may be known by its sessile ovate-oblong lvs. and branched peduncles. Intro. into S. Calif. by Franceschi.—*E. apiculata*, DC., Chile, has oval apiculate lvs. shorter than the mostly 1-fld. peduncles, and a pubescent infl. Gt. 890. Perhaps not now grown in N. Amer.—*E. cauliflora*, DC., bears fls. and frs. in sessile clusters along the woody branches and the main trunk down nearly to the ground: fr. about  $\frac{3}{4}$  in. diam., purple. Brazil. Intro. by Franceschi, and by U. S. Dept. Agric. (as *Myrciaria cauliflora*, Berg).—*E. costaricensis*, Berg., lvs. oblong, 2–3 in. long: fls. in sessile axillary umbels; pedicels  $\frac{1}{4}$  in. long: fr. obovoid, glabrous, small. Cent. Amer.—*E. edulis*, Vell. Branchlets, petioles, and young foliage ferrugineous-pubescent: lvs. willow-like, slenderly acuminate: fr. orange-color or yellow, downy, the size of an apple. Brazil. Intro. by Franceschi, and by the U. S. Dept. Agric. (as *Myrciaria edulis*, Skeels). Stands drought well.—*E. littoralis*, Panch. Lvs. spatulate, obtuse, subcordate at base: fls. sessile, fasciculate-congested; infl. pubescent: fr. puberulent, subglobose, about  $\frac{1}{2}$  in. diam., fragrant, sweet to the taste. New Caledonia. Intro. into Calif. by Franceschi.—*E. Luma*, Berg.—*E. apiculata*.—*E. Mato*, Griseb. Lvs. ovate, obtuse, about  $1\frac{1}{2}$  in. long: fls. solitary on peduncles much shorter than lvs. Argentine. Intro. by Franceschi, who describes the fr. as orange-colored, ribbed, and about 1 in. diam., and by the U. S. Dept. Agric.—*E. myriophylla*, Casar. Growing parts pubescent: lvs. mostly ternate, very narrowly linear,  $\frac{3}{4}$ – $1\frac{1}{2}$  in. long, much exceeding the solitary peduncles. Brazil.—*E. pinguens*, Berger. Young parts pilose: lvs. elliptic-oblong, spine-tipped, 2–3 in. long,  $\frac{3}{4}$ –1 in. broad, much exceeding the simple peduncles in their axils: fr. depressed-globose, puberulent, small. Brazil. Intro. by Franceschi, and by the U. S. Dept. Agric.—*E. pyriiformis*, Camb. Lvs. myrtle-like but white tomentose beneath, about equaled by the branched peduncles: fr. pear-shaped, yellow, puberulent, edible. Brazil. Intro. in Calif. by Franceschi.—*E. Ugni*, Hook & Arn.—*Myrtus Ugni*.—*E. Uvalha*, Camb., not Miq. Growing parts and infl. pubescent: lvs. oblong, narrowed at base, obtuse, 1–2 in. long, much exceeding the simple peduncles: fr. yellow, size and shape of a small pear, edible. Brazil. Intro. by Franceschi.

HARVEY MONROE HALL.

EULÁLIA: *Miscanthus*.

EULÔPHIA (Greek, *handsome crest*). *Orchidaceæ*. Terrestrial orchids, requiring warmhouse conditions.

Rather small plants with membranaceous lvs. and conspicuous pseudobulbs: scape basal, several-fld.; sepals and petals spreading, similar, ascending; labellum 3-lobed; pollinia 2.—About 50–60 species, in the tropics of both hemispheres. The cult. of *Calanthe* will apply to this genus.

*maculata*, Reichb. f. Pseudobulbs ovate, compressed: lvs. ovate, spotted or blotched: fls. small; upper sepal hood-shaped, lateral ones acuminate, reddish brown; petals broader, white or pale rose; labellum cordate, with 2 crimson spots, triangular in outline, near the base, otherwise white. Brazil. B.R. 618 (as *Angræcum*).

*scripta*, Lindl. Lvs. linear, subdistichous: fls. purple and yellow; sepals and petals linear-oblong; labellum 3-lobed, lateral lobes rotund at the apices. Madagascar.

*E. Côlee*, Rolfe. A slender-growing species with aloe-like lvs.—*E. Lubbersiana*, Laurent & Th. Dur. Allied to *E. maculata*: lvs. dark green, marbled with white. Afr.—*E. nuda*, Lindl. Scape about 2 ft. tall, many-fld.; fls. ranging from rose-purple to pink, or yellowish green; lip nearly entire, recurved. India and China. B.M. 8057.—*E. paniculata*, Rolfe. Pseudobulbs tufted, bearing 2 strap-shaped lvs.: fls. numerous; petals and lip yellowish green dotted with purple. Madagascar.—*E. undulata*, Rolfe. Scape about 1 ft. high, of slender growth; petals and lip pale green, the latter with 3 prominent keels on the disk. Rhodesia.—*E. Woodfordii*, Rolfe. With tall many-fld. infl.; fls. green with dull claret-purple lip. Old Calabar.

GEORGE V. NASH.†

**EULOPHIÉLLA** (a diminutive of *Eulophia*). *Orchidaceæ*. Orchids in habit resembling a small cyrtopodium.

Flowers in many-fld. racemes; sepals and petals similar, concave; lip 3-lobed, spurless; column with a curved foot; pollinia 2.—Species 2. They require the conditions and treatment given Cyrtopodium.

*Elisabethæ*, Hook. Lvs. nearly 2 ft. long, plicate: scape stout; raceme many-fld.; fls. about 1½ in. across; sepals and petals white, the former marked with rose on the outside; lip white with a golden disk. Madagascar. B.M. 7387. G.C. III. 45:407. C.O. 1. O.R. 6:177; 20:137.

*Peetersiana*, Kränzl. Bulbs 1 ft. long; raceme dense; fls. nearly 3 in. across, rose-purple; lip with a golden blotch. Madagascar. G.M. 51:267. C.O. 2. O.R. 6: frontispiece; 20:138.

*E. Hämelinii*, Rolfe. Resembling *E. Peetersiana* in habit but lvs. narrower and fls. smaller. Madagascar.

GEORGE V. NASH.

**EUÓNYMUS**: *Eonymus*.

**EUPATÓRIUM** (named for an ancient king of Pontus said by Pliny to have employed one of this group of plants in medicine). *Compósitæ*. JOE-PYE WEED. THOROUGHWORT. BONESET. HEMP AGRIMONY. MIST-FLOWER. Chiefly perennial herbs, a few species annual, many of the tropical ones shrubby or even arborescent; some of them hardy border plants, others grown in coolhouses as florists' plants, and others in warmhouses for the attractive foliage.

Heads rayless, mostly in dense flat-topped or rounded clusters, less frequently in open panicles, the florets (rarely 1-4) mostly 5 or more in each head, perfect, the 2 style-branches long, threadlike or club-shaped, protruding far out of the tube of the floret; involucre cylindrical to hemispherical, its scales in 2 to many overlapping ranks: achenes 5-angled, crowned with a well-developed pappus of hair-like mostly white bristles: lvs. mostly opposite: fls. purple, rose-colored or white, more rarely lilac or bluish violet, never yellow.—At least 600 species, chiefly of Mex., the W. Indies, and Trop. S. Amer. Certain species, now botanically placed in *Eupatorium*, still appear in trade catalogues and seed-lists under the names *Hebeclinium* and *Conoclinium*. Others have been confused with *Ageratum*.

Of this large and varied genus relatively few species have been brought into cultivation. Of these, there are two classes, namely certain warm-country species adapted only to glasshouse culture, and on the other hand a few native North American species (as well as the hemp agrimony of Europe), more or less tractable in cultivation, especially as components in making up mixed hardy borders. The glasshouse species are seen only in the larger or amateur collections, as a rule, although a few have been long in European cultivation. Of the hardy species, some, reputed medicinal, are found in old gardens. The glasshouse species demand the general treatment of *Piqueria* (*Stevia* of florists)—a cool or intermediate temperature and pot culture. They are easy to grow, and propagate readily by cuttings. They are useful for winter bloom, the heads, though individually small, being aggregated in showy masses.

## KEY TO THE SPECIES.

- A. Glasshouse or warm-country species.
  - B. Florets pink, purple, lilac, or violet.
    - C. Involucral scales not ending in hairy tails.
      - D. Shape of lvs. ovate; lf.-stalks long.
        - E. Lvs. heart-shaped.
          - F. Sts. covered with dense reddish wool..... 1. *atrorubens*
          - FF. Sts. green.
            - G. Panicle dense, terminal: lvs. mucronate-toothed... 2. *megalophyllum*
            - GG. Infl. lax, partly axillary: lvs. crenate-toothed.... 3. *Purpusii*
            - EE. Lvs. pointed or blunt at base... 4. *ianthinum*
            - DD. Shape of lvs. lanceolate or oblong; lf.-stalks short.
              - E. Lvs. alternate; heads many-fld.. 5. *Lasseauxii*
              - EE. Lvs. opposite; heads 5-12-fld... 6. *serrulatum*
          - CC. Involucral scales ending in hairy, colored tails..... 7. *hecatanthum*
        - BB. Florets white or nearly so (the pappus sometimes colored).
          - C. Lvs. leathery, lance-oblong, glabrous, entire..... 8. *araliæfolium*
          - CC. Lvs. not leathery, usually somewhat toothed and hairy.
            - D. Lf.-blade elliptic-lanceolate, decurrent and crisped on short stalk..... 9. *micranthum*
            - DD. Lf.-blade round-ovate, toothed even to the decurrent base.... 10. *conspicuum*
            - DDD. Lf.-blade not decurrent on petiole.
              - E. Plant glandular-sticky.
                - F. Heads about ¼ in. diam.... 11. *glandulosum*
                - FF. Heads about ½ in. diam.... 12. *probum*
                - EE. Plant not glandular-sticky.
                  - F. Lvs. velvety beneath: infl. broad rounded corymb.... 13. *vernale*
                  - FF. Lvs. sparingly hairy or soon glabrate.
                    - G. Shape of lvs. round- or triangular-ovate; margins toothed.
                      - H. Lf.-blade small, ½-1½ in. long..... 14. *glechonophyllum*
                      - HH. Lf.-blade larger, 2-4 in. long..... 15. *pazcuarense*
                    - GG. Shape of lvs. elliptic-ovate; margins nearly or quite entire..... 16. *glabratum*
                    - GGG. Shape of lvs. narrowly lanceolate..... 17. *riparium*
          - AA. Hardy or border plants.
            - B. Florets flesh-colored, reddish or bluish-purple.
              - C. Lvs. lance-oblong, merely toothed, mostly whorled..... 18. *purpureum*
              - CC. Lvs. deeply 3-parted, opposite.... 19. *cannabinum*
              - CCC. Lvs. broadly ovate, opposite, merely toothed..... 20. *cælestinum*
            - BB. Florets white or nearly so.
              - C. Lvs. perfoliate (united around the st.)..... 21. *perfoliatum*
              - CC. Lvs. not perfoliate.
                - D. Lf.-blade lanceolate, the base narrowed and scarcely stalked.

- . Scales of involucre blunt,  
 gray-velvety.....22. *altissimum*  
 EE. Scales sharp, smoothish, with  
 thin white edge.....23. *album*  
 DD. Lf.-blade ovate-lanceolate, sessile  
 by a rounded base.....24. *sessilifolium*  
 DDD. Lf.-blade broadly ovate, usually  
 well stalked.  
 E. The lvs. taper-pointed, sharply  
 toothed.....25. *urticæfolium*  
 EE. The lvs. mostly blunt and  
 bluntly toothed.....26. *aromaticum*

1. *atrórubens*, Nichols. (*Hebeclinium atrórubens*, Lem.). Lvs. large, ovate, short-stalked, heart-shaped at base, opposite, toothed, covered on the edge and veins with long reddish or claret-colored hair; heads red or purple, in a very large red-rayed truss. S. Mex. I.H. 9:310.—A stately species with fine foliage and richly colored fls., but said to be difficult to grow. Rare in cult. Closely related, if not identical, is *E. grandiflorum*, André, though figured with smaller heads of redder color. R.H. 1882:384.

2. *megalophyllum*, Klatt (*Hebeclinium megalophyllum*, Lem., not DC. *H. megalophyllum*, Lem.). Half-shrub, robust: lvs. opposite, round, more or less heart-shaped, very large, the lower sometimes more than a foot in diam., veiny; heads in large clusters (1-1½ ft. broad); florets rose, the long hairlike styles conspicuous, bluish. S. Mex. R.H. 1866, p. 351. Gt. 16:548.—Fine showy species with rich foliage, but apparently rare and not recently in trade. Needs richly manured soil, much light, and frequent replanting.

3. *Purpúsi*, Brandegee (*E. petiolare*, Hort., not Moc. & Sessé). Smoothish or (var. *monticolum*, Brandegee) sticky-hairy, loosely branched: lvs. round-ovate, commonly heart-shaped, shortly taper-pointed, bluntly and rather coarsely toothed; heads slender-stalked, ½ in. diam.; florets at first white, changing rapidly to pinkish lilac. Low. Calif. G.C. III. 35:163.—Attractive, rapid-growing, herbaceous, tender. Weak and needing support.

4. *ianthinum*, Hemsl. (*Conoclinium ianthinum*, Morr. *Hebeclinium ianthinum*, Hook.). Somewhat shrubby, the thickish round sts. at first covered with a rusty purplish pubescence: lvs. large, ovate, long-stalked, opposite, pointed or blunt (but not heart-shaped) at base, somewhat hairy on both surfaces, serrate: fls. light violet, in a large compound terminal corymb. S. Mex. B.M. 4574.—A luxuriant species with heavy foliage, of easy pot cult. in a warmhouse.

5. *Lasseauxii*, Carr. (*Ageratum Lasseauxii*, Carr. *Conoclinium Lasseauxii*, Dur.). Habit of *Ageratum*, densely covered with short glandular hairs: lvs. alternate, oblong-lanceolate, narrowed at each end, bluntly toothed: heads in small compact unequally stalked clusters; florets very numerous, at first white, at maturity a vivid rose-color. Temp. S. Amer. R.H. 1870:90.—Intro. to European hort. in 1870. Attractive bedding plant, but apparently rare. Probably not fully hardy though less tender than most of the glasshouse species. Prop. easily and flowers continuously; 1-2 ft. high.

6. *serrulatum*, Hort. Shrub with lance-shaped, pointed, sharply and unevenly toothed, short-stalked lvs., very unequal involucre scales, and showy reddish lilac heads in large dense flat-topped clusters; florets 5 in each head. In European hort., and said to come from S. Brazil. R.H. 1894:304. Gt. 44, p. 570. G.C. III. 18:265.—Three to 6 ft. tall. Choice, but certainly not the true *E. serrulatum*, DC., which has much narrower finely and evenly serrulate lvs. and 11-12-fld. heads.

7. *hecatanthum*, Baker (*Hebeclinium Urolepis*, DC.). Robust annual, like a large *ageratum*: lvs. opposite, stalked, round-heart-shaped: heads showy, bluish purple; florets numerous (about 75); involucre scales

ending in similarly colored hairy appendages. Temp. S. Amer.—Promising species, worthy of trial as a bedding plant.

8. *araliæfolium*, Less. (*E. omphaliæfolium*, Kunth & Bouché). Soft-wooded shrub with thick and shining oblong-lanceolate lvs. 3-8 in. long; heads loosely panicle; involucre scales conspicuously unequal, the outer short and calyx-like, the inner 3-4 times as long; florets white. S. Mex. and Guatemala. Gt. 2, p. 4, t. 39.—From low and moist tropical habitat and presumably very tender. Rare in cult. and not noticed recently in trade. Needs rich leaf-mold, moist air, and high temperature. Prop. by cuttings. Flowers in March.

1434. Leaves of glasshouse Eupatoriums. a, *E. riparium*; b, *E. vernale*; c, *E. glandulosum*; d, *E. glabratum*. (× ¼)

9. *micranthum*, Less. (*E. ligustrinum*, DC. *E. Mörtsii*, Hort. *E. Weinmannianum*, Regel & Koern. Many other hort. names, for which see Gt. 22, p. 36). Lvs. opposite, elliptic-lanceolate, pinnately veined, the blade somewhat toothed and slightly decurrent in narrow crisped wings upon the short lf.-stalk: heads small and few-fld. but very numerous in large round-topped terminal corymb; florets white, but pappus pink-tinged to deep rose. Mex. Gt. 16, p. 260, t. 555, figs. 1-3. Gn. 47, p. 444. G.C. II. 5, p. 53.—Upright shrub rather widely cult. since about 1830 under a great variety of names, but chiefly as *E. Weinmannianum*.

10. *conspicuum*, Kunth & Bouché (*E. grandifolium*, Regel). Shrubby: lvs. opposite, large, thin, triangular-ovate, finely and sharply toothed to the very base, which is somewhat decurrent upon the long lf.-stalk: fls. white, in ample lax panicles, almond-scented. Guatemala. Gt. 1, p. 102, t. 12.—Planted out in summer forms a luxuriant shrub, attractive on account of its excellent foliage. Best prop. by cuttings placed in warm bed about the end of August. Winter-bloomer in glasshouse.

11. *glandulosum*, HBK. (*E. adenophorum*, Spreng. *E. adenanthum*, Hort., not DC. *E. trapezoidum*, Kunth.

*E. americanum*, Hort.). Fig. 1434. Diffuse and often decumbent herb, the slender round branches, petioles, and pedicels finely glandular-puberulent: lvs. triangular-ovate or rhombic-ovate, thinish, slender-stalked, taper-pointed, coarsely and sometimes unevenly crenate-dentate, sparingly puberulent beneath: heads pure white, ageratum-like, in close clusters. Mex. B.R. 1723.—Easy in pot cult. and not very tender, flowering in late autumn or early winter. Cuttings strike root readily. Var. *foliis variegatis*, Hort. Lvs. variegated.

12. *pròbum*, N. E. Br. Very viscid like the preceding, probably more tender: lvs. similar: heads decidedly larger,  $\frac{1}{2}$  in. diam. Peru. G.C. III. 7:321.—Recommended as promising and cult. in a few English conservatories. Apparently not yet in the trade.

13. *vernale*, Vatke & Kurtz. (*E. triste*, Hort., not DC. *E. triste*, Hort.). Fig. 1434. Strong herb (slightly woody in the wild), with hairy sts.: lvs. oblong-ovate, long-stalked, taper-pointed, serrate, finely hairy above,

1435. *Eupatorium perfoliatum*. ( $\times \frac{1}{5}$ )

paler and grayish velvety beneath, veiny, 3–5 in. long: fls. bright white, the heads in an ample terminal corymb; involucre scales long, narrow, green. Mex. Gt. 22:750.—Easy in pot cult. becoming popular for cut-fls.

14. *glechonophyllum*, Less. (*Ageratum conspicuum*, Hort.). Low, branching half-shrub, very leafy: lvs. small,  $\frac{1}{2}$ –1 (rarely 2) in. long, triangular-ovate, sharp-pointed, bluntly few-toothed, thin and nearly glabrous, on slender stalks: heads borne on threadlike pedicels in small or medium-sized flattish clusters. Chile.—Tender greenhouse perennial, but flowering in the open the first year if seeds are sown early. Closely related, if not actually identical was the *E. Haageanum*, Regel & Koern. intro. into European hort. in the middle of the 19th century (see Gt. 16, p. 260, t. 555, figs. 4–6).

15. *pazcuarense*, HBK. Puberulent but not glandular: lvs. opposite, stalked, round-ovate, light green, 2–4 in.

long, taper-pointed, sharply or bluntly toothed: heads very numerous in a wide (3–10 in.) flattish corymb. Uplands of Mex.—Essentially herbaceous, 1–3 ft. high. Recently intro. in cult. in S. Calif. Promising for cut-fls. and as a window plant.

16. *glabràtum*, HBK. (*E. elegans*, Hort. *E. latifolium*, Hort.). Fig. 1434. Shrubby, erect, with slender hard glabrous brown sts.: lvs. of firm texture though scarcely leathery, small, lance-oblong or ovate-oblong, tapering into a strong rather short petiole, blunt or pointed, wavy-margined or small-toothed: fls. (sometimes blush) in ascending cymose clusters, together forming a long terminal leafy panicle. Uplands of Mex.

17. *ripàrium*, Regel. Fig. 1434. Diffuse, becoming woody at base, 2 ft., the sts. slender, puberulent and usually reddish: lvs. opposite, long-lance-shaped, taper-pointed and at base narrowed to a long petiole, prominently 3-ribbed, toothed: heads in rather compact long-stalked clusters. Mex. Gt. 15:525. Gn. 40, p. 134.—Good winter bloomer. Best for florists. Readily cult. in coldhouse.

18. *purpùreum*, Linn. JOE-PYE WEED. Lvs. whorled, commonly in 5's and 6's, oblong or lanceolate, taper-pointed, coarsely serrate: heads in large compound clusters, pale purple or flesh-colored, rarely almost white. N. Amer.—Common and variable. Tall, rank plant of low grounds (reaching 8–9 ft.), good for bold effects in border or against shrubbery. Var. *maculàtum*, Darl. Of lower growth: lvs. commonly in 4's, ovate-oblong, roughish-pubescent: heads in smaller clusters, more deeply colored. Var. *foliòsum*, Fern. Similar but with the infl. surpassed by the long upper lvs. Var. *amènum*, Gray. Still lower (2 ft. high), smoothish: lvs. sometimes merely opposite.

19. *cannabinum*, Linn. HEMP AGRIMONY. Resembling Joe-Pye weed in general habit and with similar pale purple heads in terminal clusters: lvs. opposite, but deeply 3-parted in a manner to suggest verticillate lvs. Eu.—Common. May be used like the preceding species but less desirable. Thrives best in limy alluvial soil. Eng. Bot. 6:428.—The Asiatic *E. Kirilowi*, Turcz., is a very nearly related plant of lower growth (1–3 ft.), with narrower (linear-oblong) coarsely toothed lf-segms., the lateral often much reduced. Strict herb with dense terminal corymb of dull greenish purple heads. Gt. 24:850.

20. *cœlestinum*, Linn. (*Conoclinium cœlestinum*, DC.). MIST-FLOWER. Somewhat pubescent: lvs. opposite, stalked, triangular-ovate, somewhat cordate, thin, coarsely toothed: heads as in *Ageratum* in compact clusters, many-fl'd., light blue to violet. N. J. to Mich., Kans., and southward.—Perennial herb, late-blooming, heliotrope-fl'd. Appropriate to low borders.

21. *perfoliàtum*, Linn. BONESET. THOROUGHWORT. Fig. 1435. Hairy: lvs. lance-oblong, the pairs united at base about the st., wrinkled, remotely toothed or entire, taper-pointed: heads in dense terminal compound cymes. N. Amer., common in low rich soil.—Stout, slightly rank-smelling plant, 2–3 ft. high, long used in domestic medicine and found in old gardens. Excellent for striking effects, especially in low grounds. Fls. grayish white or in a comparatively rare variety (forma *purpùreum*, Brit.) bluish purple. In var. *truncàtum*, Gray, the lvs. (at least the upper ones) are rounded or truncate at the sessile base, not united about the st. A peculiar form apt to be encountered occasionally in large cultures.

22. *altissimum*, Linn. Grayish green, downy, much branched: lvs. opposite, narrowly lance-shaped, tapering to both ends, short-stalked, remotely toothed or entire: heads only 5-fl'd. Pa. to Minn., Neb., and southward.—Tall, vigorous herb, 4–8 ft. high, in open places and dry soil. Not very ornamental. See page 3568

23. *album*, Linn. Rough-hairy: lvs. opposite, lance-oblong, coarsely serrate, essentially sessile, veiny: involucrel scales scarious-margined: florets white. L. I., southward near the coast.—Somewhat attractive for border planting and specially suited to poor sandy soil.

24. *sessilifolium*, Linn. UPLAND BONESET. Lvs. oblong-lanceolate, gradually tapering almost from the rounded sessile base to the apex: heads 5-fld., white. Vt. to Mo. and southward.—A trim, smooth highly attractive hardy species. Thrives best in limy alluvial soil.

1436. *Eupatorium urticaefolium* ( $\times \frac{1}{2}$ )

25. *urticaefolium*, Reichard (*E. ageratoides*, Linn. f.). WHITE SNAKE ROOT. Fig. 1436. Lvs. opposite, thin, long-stalked, ovate with broad base, acuminate, coarsely and sharply serrate, green on both sides: heads small in loose but ample clusters; florets bright white. E. N. Amer. Mixed woods, common.—Neat, smoothish, branching herb, 2–4 ft. high. One of the best of the perfectly hardy summer-blooming species.

26. *aromaticum*, Linn. Much like the preceding but usually hairy: lvs. thickish and blunt or scarcely pointed, blunt-toothed: later-flowering, not aromatic. Mass. and southward near the coast.—Suited to very sandy soil. Var. *melissoides*, Gray (*E. Fraseri* and *E. cordifolium*, Hort.). Slender, roughish, strict: heads 5–12-fld.: lvs. subcordate, ovate or oblong, obtuse, the petioles often very short. S. E. U. S.—Also suited to poor and sandy soil, but more tender than the typical form.

The following species are said to have been recently intro. into European horticulture and to promise well: *E. deltoideum*, Jacq. A soft-wooded half-shrub with opposite triangular-hastate crenately toothed lvs. 3–5 in. long and somewhat pale and slightly velvety beneath, the basal lobes widely spreading acute: lf.-stalks 1–3 in. long: heads of rosy purple fls. in thyrsoid panicles; involucrel scales linear, very sharp, scarcely imbricated. S. Mex. A glasshouse species with striking foliage.—*E. herbaceum*, Greene (*E. arizonicum*, Hort.). An erect smooth or merely pulverulent perennial 1–3 ft. high, with opposite triangular-ovate pale green lvs. 1–3 in. long with rounded basal lobes, toothed sides, and rather short but slender stalks: fls. white; heads in broad rounded terminal clusters. S. W. U. S. Half-hardy and suited to dry places. *E. japonicum*, Thunb. Erect perennial resembling *E. cannabinum*, with dull purplish to greenish white fls. in flat clusters: lower lvs. deeply 3-parted, the upper simple: not very attractive.

B. L. ROBINSON.

**EUPHORBIA** (classical name; said by Pliny to be in honor of King Juba's physician; possibly from the Greek for fat). *Euphorbiaceae*. MILKWEED (improperly) WOLFS-MILK. SPURGE. The last name, most often applied to the genus as a whole, belongs more properly to the common herbaceous species and especially to *E. Lathyris*. Of very diverse habit, from succulent cactus-like trees to low or prostrate herbaceous weeds; planted mostly in the open, but some kinds grown under glass as oddities and some as florist's plants.

The genus is characterized by the single pedicellate, pistillate fl. without floral envelopes, or with only a rudimentary calyx, surrounded by numerous staminate fls., each consisting of a single stamen separated from its pedicel only by a joint; the whole infl. surrounded by a more or less cup-shaped involucre with 5 lobes and 1–5 glands is called a cyathium. The involucre is regular or nearly so; the glands free from one another: the fr. an explosive caps., with 3 carunculate seeds; the staminate fls. are usually subtended by

minute bracts.—One of the largest plant genera, of not less than 700 and probably over 1,000 species, occurring in most temperate and tropical regions. Many are desert plants and the greater number grow in dry and sterile places. *Euphorbia* is distinguished from the nearest related genera, *Pedilanthus* and *Synadenium*, by its regular or nearly regular involucre, which in *Pedilanthus* is protuberant on one side of the base and contains the glands, and by the free involucrel glands which in *Synadenium* are united into a ring. Some of the fleshy species are very similar to succulent cacti and *Asclepiadaceae*. One long grown under the name of *E. pendula*, Boiss., is a *Sarcostemma* according to N. E. Brown. For *E. tithymaloides*, see *Pedilanthus*; for *E. Grantii*, Hort., and *E. arborea*, Hort., see *Synadenium*.

Monographed by Boissier in DeCandolle's *Prodromus*, 15, pt. 2 (1862). See local floras and Norton, Rept. Mo. Bot. Gard. 11, for native species. See also Fobe, in *Monatsschrift für Kakteenkunde*, 8:42 (1898) and Berger, *Sukkulente Euphorbien*, a manual of the cactus-like species in cultivation. The recent work of N. E. Brown of Kew in *Flora of Tropical Africa* and *Flora Capensis* describes and gives keys to practically all the African species, which include nearly all the succulent ones, both wild and cultivated. Although the vegetative form varies remarkably, so that the various sections of the genus are considered of generic rank by many authors, the floral characters are very similar and so inconspicuous as to be of little importance generally in a horticultural work.

Most of the species have abundant milky juice, and the cactiform kinds have been thus distinguished from cacti, but many cacti also have milky juice. The juice of many species is acrid-poisonous, especially if it comes in contact with mucous membranes or open sores. The juice from some of the species is used in medicine as a purgative.

Many of the fleshy species are cultivated by lovers of succulents for their curious shapes; and a few are valuable for their ornamental foliage. The flowers are usually too minute to be noticeable. Some, like *E. corollata* (Fig. 1437), *E. maculata*, *E. Cyparissias* and *E. marginata*, are weeds in America, but not troublesome. The great majority of the species are insignificant herbs. The species are remarkably free from injurious insects, and are rarely attacked by a few fungi.

The fleshy species are grown much the same as cacti, but the culture is less difficult, and they do well with warmer treatment. In winter they are kept in a dry and cool house, 50° to 55° F., with good light and little water. Drips must be carefully avoided. In summer the pots should be plunged outdoors in hot dry situations, with a moderate supply of water and especially good drainage. It is better to protect them from continued rain, but most species do well without this. The more fleshy species, like *E. Caput-Medusae*, *E. mammillaris*, and *E. meloformis*, require more heat and better care than the others. They have to be watered with great care in winter. The air of most greenhouses is too damp for them if the requisite low temperature is maintained. The winter conditions of air and temperature in ordinary living-rooms make them ideal for the succulent euphorbias. Species like *E. neriofolia* need water in the growing season and dry conditions after the

1437. *Cyathium* of *Euphorbia corollata* ( $\times 2$ ). The pistillate flower is at 8, surrounded by several staminate flowers arising above the involucrel glands with their five oblong spreading petaloid appendages. No. 3.

leaves fall. The shrubby species, like *E. atropurpurea* and *E. dendroides*, do well with the treatment of the more fleshy kinds. See D. A. W. and F. S. Curtis, in Sharon Cactus Guide, March and May, 1897.

The few hardy species of ornamental value make good border plants or are suitable for the rockery. *E. epithymoides* usually known in gardens as *E. polychroma*, is one of the best herbaceous perennials, forming a hemispherical clump with beautiful yellow foliage of different shades when in bloom. *E. palustris* and related species are similar but erect and not compact.

The succulent species can nearly all be propagated by cuttings. These are taken best in early summer, allowed to dry somewhat and then planted in sand, charcoal or a mixture of these. Coal-ashes are used effectively by some. When seeds can be procured, they may be used in propagation. Grafting, as is sometimes practised with cacti, is possible. Potting soil need not be rich. A coarse sandy loam, or, some say, any kind of soil will do.

*E. pulcherrima* and *E. fulgens* are good winter-flowering greenhouse plants, and require special treatment. *E. fulgens* succeeds well in the warmest parts of the house, in pots, or best planted out like roses and trained upon the wall or strings. It is propagated from cuttings taken in June, when the old plants have started to grow, kept in a warm frame until rooted, and then kept growing with heat, any transfers being made with as little root disturbance as possible. If stocky show plants are wanted, several cuttings may be planted in one pot and checked two or three times during summer by repotting, and kept pinched back freely to secure branches. They are best kept cooler when in flower, but are very sensitive to cold or sudden changes in temperature. After flowering they are kept dry for a few months. For the cut sprays they are best grown from cuttings each year. They last very well when cut,

usually taken from the young wood. Successive sets of cuttings may be made at later periods if different-sized plants are wanted. When well started, the potted plants are plunged outdoors till September, with plenty of water, light and sunshine and good drainage. They do well in rich heavy loam in 5-7-inch pots. They are liable to drop their leaves if exposed to cold or other unfavorable conditions. In autumn they are transferred to the greenhouse, with moderate temperature.

When the bracts begin to appear, give more heat and some manure water to expand them. When in flower, reduce the temperature to preserve them longer. After flowering the pots may be stowed away in a dry warm place till spring,—under the benches will do. When the buds are cut the great objection is that they wilt easily. This may be obviated by keeping them in water for a few days before using. See Grieve, G.C. III. 9:106, and Hatfield in Garden and Forest 9:496. See article *Poinsettia* for further treatment.

*Euphorbia splendens* is another winter bloomer, and may be treated as the succulents, with more heat and water. It will do well in living-rooms, and bears some flowers all the year. It bears rough treatment well, and is propagated by cuttings from the young growth, which root with the greatest ease.

In tropical and subtropical regions many of the tree-like or succulent euphorbias make fine outdoor ornaments. The poinsettia is a magnificent landscape ornament in California, West Indies and so on. In Southern California the poinsettia is propagated by sticking canes 3 feet long in the ground from April on, these growing and blooming, often profusely, the first season. In the West Indies and Florida, some of the thorny tree-like forms, especially *E. lactea*, are grown as hedges, their thick, erect thorny branches making an almost impenetrable barrier. This and other species are grown also as specimen plants. See *Succulents*.

1439. *Euphorbia fulgens* ( $\times \frac{1}{2}$ ). No. 5.

1438. *Euphorbia marginata* ( $\times \frac{1}{2}$ ). No. 1

The culture of the poinsettia is very similar. To secure plants with large heads, the general plan is to grow from cuttings annually, but the old plants may be continued. Old plants that have been resting may be introduced to heat and moisture in late spring, and will soon give a liberal supply of cuttings, which are

A. Glands of the involucre with petal-like appendages (almost none in 4): slender-branched herbs or rarely shrubs not spiny: lvs. entire. Section ADENOPETALUM. The Section ANISOPHYLLUM, genus *Chamæsyce* of some, differs in having small opposite lvs., unequal at base, stipules present, fls. small, glands 4. It contains most of the low herbaceous wild euphorbias of U. S., such as *E. maculata*, Linn., *E. Prestii*, Guss., *E. serpens*, and *E. capitata*; names from this group occur in American catalogues, but the species to which they properly belong are inconspicuous weeds. *E. lorifolia*, Hillebr., of Hawaii, has recently been investigated as a possible source of rubber. (Descriptions of these species will be found in the floras.)

## B. Stipules present.

1. *marginata*, Pursh (*E. variegata*, Sims). SNOW-ON-THE-MOUNTAIN. GHOST-WEED. Fig. 1438. Annual, about 2 ft. high, pubescent, dichotomously many-branched: lvs. numerous, light green, ovate-subcordate to oblong-lanceolate, 1-3 in. long, the upper white-margined, often entirely white: involucreal glands with large white appendages. July-Oct. Plains from Dak. to Texas and extending eastward. B.M. 1747. Gt. 30:218. V. 2, p. 281; 5, p. 64. G.W. 13, p. 305.—Hardy annual, used for its white foliage in bedding and mixed borders in sunny situations.

2. *sanguinea*, Hort. (*E. hæmatodes*, Boiss.?). A tall shrub: lvs. ovate, obtusely pointed, in whorls of 3, red when young to deep bronze or purplish red later.—This handsome plant of unknown nativity is cult. in S. U. S. While it is not possible to classify it exactly without fls. and fr., the foliage characters indicate its relationship to *E. cotinifolia*, Linn.

1440. *Euphorbia pulcherrima* ( $\times \frac{1}{2}$ ). No. 8.

## BB. Stipules absent or microscopic.

## c. Plant a perennial herb.

3. *corollata*, Linn. (*Tithymalopsis corollata*, Klotzsch & Garcke). FLOWERING SPURGE. Fig. 1437. Plant  $1\frac{1}{2}$ -3 ft. high, usually glabrous, slender and diffusely branched above: lvs. ovate-oblong to lanceolate, 1-2 in. long, those of the infl. much smaller and opposite: involucreal glands 5, with conspicuous white appendages. July-Oct. On rather dry soil E. U. S. B.M. 2992. L.B.C. 4:390. F.R. 1:969.—A hardy herbaceous perennial used like *gypsophila* for cutting, and as a bedder in

light soil. There are many variations in size, shape, color and pubescence of plant, lvs. and infl.

4. *Ipecacuânha*, Linn. (*Tithymalopsis Ipecacuânha*, Small). IPECAC SPURGE. Only the forking infl. (3-6 in.) above ground, with its red or green glabrous, opposite lvs. varying from oval to linear on different plants, the alternate lvs. of the short st. usually subterranean and scale-like: cyathia long peduncled; appendages of glands rudimentary. April. Sandy soil E. U. S. L.B.C. 12: 1145. B.M. 1494.—*E. geniculata*, Ort., is sometimes cult. under this name. It is a plant of Trop. Amer., related to *E. heterophylla*, but with broader lvs. the upper whitish at base.

1441. *Euphorbia heterophylla* ( $\times \frac{1}{4}$ ). No. 9.

## cc. Plant a shrub.

5. *fulgens*, Karw. (*E. jacquiniæflora*, Hook.). SCARLET PLUME. Fig. 1439. Small shrub with slender drooping branches: lvs. long-petioled, lanceolate, bright green: cyathia in small axillary cymes, with the conspicuous appendages to the 5 involucreal glands bright scarlet. Mex. B.M. 3673. R.B. 39:41. F.C. 2:55. R.H. 1905:440. Gn. 33:486; 39, p. 239; 67 p. 73. V. 2, p. 74. A.F. 16:1551. G.M. 53:89. G. 4:593. P.M. 4:31. Gng. 10:76.—A handsome winter-blooming plant, used for cut-fls. or for specimen plants.

6. *miseria*, Benth. Lvs. small, obovate, pubescent, clustered at the end of crooked branches: fls. inconspicuous. S. Calif. and Mex.—Recently catalogued in the Calif. trade.

7. *antisiphilitica*, Zucc. (*Trichostigma antisiphilitica*, Klotzsch & Garcke). CANDELILLO. Slender, erect, rod-like branches 1-3 ft. high, almost leafless Mex.—The plants yield a useful wax and are sometimes grown in collections of succulents.

## AA. Glands of involucre without petal-like appendages. (Nos. 8-65)

B. St. herbaceous or shrubby, not fleshy: lvs. well developed, the upper colored: stipules minute: infl. cymose. Section POINSETTIA.

8. *pulcherrima*, Willd. (*E. Poinsettiana*, Buist. *Poinsettia pulcherrima*, Graham). POINSETTIA. EASTER FLOWER. CHRISTMAS FLOWER. LOBSTER FLOWER. MEXICAN FLAME-LEAF. Fig. 1440. Shrub 2-10 ft. high, branched: lvs. ovate-elliptical to lanceolate, entire, sinuate toothed or lobed, or panduriform, 3-6 in. long, somewhat pubescent, the upper narrower, more entire to even linear-lanceolate and of the brightest vermilion-red: involucre 2-3 lines wide, greenish, with one large yellow gland. Nov.-March. Moist, shaded parts of Trop. Mex. and Cent. Amer. B.M. 3493. G.C. III. 21:125, 193. F.C. 1:33. Mn. 7, p. 67. Gn. M. 2:209.—Sometimes cut, usually used for specimen plants and in masses, often used in decorations. A gorgeous plant. Var. *plenissima*, Hort., has the fls., or most of them, transformed into red bracts, giving a fuller center. G.C. II. 5:17. Gt. 28:182. F.M.

1876:200. Var. *álba*, Hort., has the upper lvs. white. R.H. 1913:228.—It is not so vigorous, blooms later and requires more heat.

9. *heterophylla*, Linn. (*E. pandurata*, Hort.? *E. havanensis*, Willd. *E. cyathophora*, Muft.). MEXICAN FIRE PLANT. HYPOCRITE PLANT. PAINTED LEAF. FIRE-ON-THE-MOUNTAIN. ANNUAL POINSETTIA. Fig. 1441. Annual, nearly glabrous, 1-3 ft. high: lvs. ovate and sinuate-toothed, or panduriform, or some of them lanceolate or linear and entire, dark green, the upper bright red at least at the base: involucre small with 1 or 2 glands. July-Sept. E. and Cent. U. S. to Peru. Mn. 2, p. 53. Gt. 39, p. 105.—Easily grown from seeds in sunny gardens and also in pots indoors. White and yellow variegated forms are in cult.

BB. *Sts. more or less fleshy, often cactus-like and spiny: lvs. small, none or soon deciduous: infl. few-branched or cyathia single: stipules minute or none (except in E. Fournieri). Section EUPHORBIA. Nos. 10-51.*

C. *Branches cylindrical or angled, not thorny: lf.-bases not thickened and elevated as podaria: lvs. alternate or crowded on the angles.*

D. *Joints or branches cylindrical or flat. Subsection TIRUCALLI.*

10. *Tirucalli*, Linn. MILK-BUSH. INDIAN TREE SPURGE. A small tree, with a dense crown of slender, cylindrical whorled branches, curving outward then erect: joints about 4 in. long, twigs  $\frac{1}{4}$ - $\frac{1}{2}$  in. thick: lvs. narrow, about 1 in. long, soon falling. S. Asia.—A striking plant for the succulent collection. Easy of cult., often grown outdoors in warm regions.

11. *riphsaloides*, Lem., is a closely related African species probably not now in cult., but the name is in use in the trade.

12. *xylophyloides*, Brongn. Shrub or tree: trunk cylindrical, much branched; branches flat or 2-angled,  $\frac{1}{2}$  in. wide, slightly toothed along the edges: lvs. minute, soon deciduous. Madagascar.

DD. *Joints or branches 4-5-angled from the decurrent lf.-bases or comb-like rows of stipules. Subsection GONIOSTEMA (No. 13) and Subsection PTERONEURÆ (No. 14).*

13. *Fournieri*, André. St. 4-5-angled, the crowded persistent stipules forming comb-like rows on the angles: lvs. large at the apex of the short thick sts.; petioles and stipules red. Madagascar region. R.H. 1896, p. 226. L.B.C. 15:1477 (as *E. lophogona*).

14. *pteroneura*, Berger. A low shrub with erect, jointed branches,  $\frac{1}{2}$  in. thick, the 5-6 angles formed by sharp low ridges decurrent from the lf.-bases: lvs. reduced, soon deciduous. Mex. (?)—Erroneously grown under the name of *E. colletioides*, Benth.

CC. *Branches succulent with thickened elevated lf.-bases (podaria).*

D. *Spines 1-2 on each side the lf.-base. Subsection DIACANTHUM. Nos. 15-38.*

E. *Podaria (lf.-bases) not united into ribs; branches nearly cylindrical: lvs. well developed.*

F. *Bracts bright red. Class SPLENDENTES.*

15. *splendens*, Bojer. CROWN OF THORNS. Fig. 1442. Sts. 3-4 ft. long,  $\frac{1}{2}$ -1 in. thick, somewhat climbing, covered with stout

spines about an inch long: lvs. few, on the young growth, obovate to oblong-spatulate, thin, bright green, 1-2 in. long: cyathia in long-peduncled dichotomous cymes, near the ends of the branches, each closely subtended by 2 broadly ovate bright red bracts. Madagascar. Flowering all the year but mostly in winter. B.M. 2902. L.B.C. 18:1713. V.

1443. *Euphorbia nerifolia*.

2, p. 74; 14, p. 16. G.C. II. 19:816 (as *E. jacquiniæ-flora*).—Coolhouse plant. The red bracts in the green lvs. on the sinuous spiny sts. are very striking. It can be trained into ornamental forms. The seedlings have larger sts. and lvs. and double spines, a smaller one below each of the ordinary ones.

FF. *Bracts not conspicuously colored.*

Class GRANDIFOLIE.

16. *nerifolia*, Linn. Fig. 1443. Arborescent or shrubby: st. obtusely 5-angled; the small mammiform podaria in rows, with short, dark-colored, divergent spines: branches somewhat whorled, bearing obovate-oblong, obtuse, thick lvs., 3-5 in. long, at the summit: small sessile cymes of greenish cyathia in the upper axils. June, July. E. Indies. Gn.M. 6:196.—The large lvs. persistent from autumn to spring. Cristate forms are in cult. Fig. 1443 shows a hedge in W. Indies.

17. *drupifera*, Schum. & Thonn. (*E. grandifolia*, Haw.). Arborescent: st. terete: branches obsoletely 4-5-angled; spines small: lvs. terminal, obovate-cuneate, obtuse or retuse, 6-10 in. long: small cymes axillary, peduncled: caps. drupaceous. Guinea.

18. *mammillösa*, Lem. Low, caespitose: branches less than an inch diam.: podaria elongated, conical, in 5 spiral rows: lvs. and spines small, soon deciduous. Nativity unknown.—Rare in cult. and not well known. Probably the plants grown under this name are something else.

EE. *Podaria united into ribs: branches 2-13-angled: lvs. usually very small or rudimentary.*

F. *Angles of the branches, 2 (rarely 3), the branches flattened. Class COMPRESSÆ.*

19. *alcicornis*, Baker. St. obtusely 5-angled, 9 ft. high or less: branches flat, except the triangular base,  $\frac{1}{2}$  in. broad: spines short, slender, dark-colored. Madagascar.

FF. *Angles of the branches 3 (sometimes 4), but the main st. often 5-angled. Class TRIGONÆ.*

G. *Sides of branches solid green-colored.*

H. *Spine-shields separated by green tissue of ribs.*

20. *antiquorum*, Linn. Shrub, 8-10 ft. high: branches erect, jointed, 1-2 in. thick, the angles repand-dentate; spine pairs about 1 in. apart; spines 1-3 lines long: lvs. very small, roundish. India. See *E. lactea*, No. 23.

21. *grandidens*, Haw. Tree, to 30 ft. high, with trunk as much as 2 ft. diam.: branches slender,  $\frac{1}{2}$ - $\frac{3}{4}$

1442. *Euphorbia splendens*. ( $\times \frac{1}{3}$ )

in. wide, numerous, whorled, erect-spreading, making a dense rounded head in older plants; sides of branches almost plane; angles deeply sinuate dentate; spine pairs  $\frac{1}{2}$ – $\frac{3}{4}$  in. apart, spines 3–5 lines long, slender, light brown to gray: lvs. very small, triangular. S. Afr.

HH. *Spine-shields united, forming a continuous horny edge to the ribs.*

22. *grandicornis*, Goebel. Fig. 1444. Shrub or small tree: branches 3–5 in. wide, deeply jointed, the angles broadly winged, lobed and sinuate, the edge zigzag or wavy; spines large, 1–2 in. long, light colored: lvs. very small, triangular ovate. S. Afr.(?).—A fine plant, with the longest spines and widest wings of all. A rapid grower, the bright pale green contrasting beautifully with the rich light brown of the spines and horny margins on young plants.

GG. *Sides of branches marbled with white or yellow.*

23. *lacteæ*, Haw. (*E. havanensis*, Hort., at least in part). Fig. 1445. Similar to *E. antiquorum*, but with a white-marbled area running through the middle of each face of the branches. E. Indies.—One of the most common succulent euphorbias in cult., of fine candelabra form, and making rapid growth. The euphorbias grown for hedges in Fla., W. Indies, etc., are chiefly this species, though some may be *E. antiquorum*. It is often confused with *E. Hermentiana*. Cristate forms are in the trade as *E. lactea monstrosa* and *E. havanensis cristata*, though these should perhaps be referred to *E. antiquorum*.

24. *Hermentiana*, Lem. Shrub, with closely erect, scarcely jointed branches, about 2 in. thick; sides strongly concave, striped or marbled with white, especially when young, angles closely dentate; spines slender, brown, 2–3 lines long: lvs. lanceolate,  $\frac{1}{2}$ – $2\frac{1}{4}$  in. long. W. Afr. G.Z. 19:101.—One of the best. The true *E. candelabrum*, Trem., but probably not the one common in cult. under that name, is distinguished from *E. Hermentiana* by its rudimentary scale-like lvs.

FFF. *Angles of the branches 4–8 (rarely 3 on some branches). Class POLYGONÆ.*

G. *Spine-shields united, forming a continuous horny edge to the ribs.*

H. *Sides of mature branches plane or slightly convex, angles not winged, branches about 2 in. diam.*

25. *Pseudocactus*, Berger. St. 4–5-angled: branches 3–5-angled, joints tapering upward from a broad base, 4–6 in. long, 2 in. or less thick, the surface with yellow U-shaped marks from center to angles; spines stout,  $\frac{1}{2}$  in. long, brown to gray. Nativity(?). J.H. III. 60:99 (as *E. lactea*).—Frequent in cult., often under the name of *E. lactea*; also as *E. marmorata* and *E. tessellata*.

26. *cœrulæscens*, Haw. (*E. virôsa*, and var. *cœrulæscens* of Berger). Low, shrubby: st. 4–5-angled: branches 3-angled at base, 4–5-angled above, 2 in. thick; joints 2 in. or less long, the sides bluish glaucous; spines stout,  $\frac{1}{2}$  in. long: lvs. triangular, scale-like. S. Afr. G.Z. 19:102.—A handsomely colored compactly

branched succulent. According to N. E. Brown, *E. virôsa*, Willd., is quite a different plant. It is probably not in cult. in Amer.

27. *Echinus*, Hook. & Coss. Branching shrub, with 6-angled st., branches ascending, about 2 in. thick, 5- or more-angled: spine pairs less than  $\frac{1}{2}$  in. apart; spines  $\frac{1}{2}$  in. long, red to gray. Morocco. G.Z. 1904:122.

HH. *Sides of mature branches concave, angles more or less winged, branches often 3–4 in. thick.*

28. *triangularis*, Desf. Tree-like: st. at first 6-angled, later cylindrical: branches whorled, divergent, then ascending, 3–5-angled, 2–4 in. thick; joints 2–12 in. long; spine pairs 3–9 lines apart; spines less than 5 lines long; spine-shields united only on stronger shoots: lvs. small, roundish. S. Afr.(?).

29. *Cooperi*, N. E. Br. Tree-like: whorled ascending branches, 3–5 in. thick, the joints broad at base and tapering upward, 6-angled, spines 5 lines long, black to gray. Natal.—A fine species.

GG. *Spine-shields separate. See also No. 28.*

H. *Sides of mature branches plane or slightly convex, angles not winged, branches less than 2 in. thick.*

30. *resinifera*, Berg (*E. San Salvador*, Hort.). A much-branched shrub: branches 4-angled, spine-shields triangular-rounded, small, 3–5 lines apart. S.W. Morocco. G.Z. 19:102.—This species yields the euphorbium gum of the ancients.

31. *canariensis*, Linn. Shrub or tree, 12–20 ft. high, with many 4–6-angled, suberect, not conspicuously jointed branches, as much as 3 in. thick; angles sub-entire; spines 2 lines long, black: lvs. almost none. Canary Is. Gn. 53, p. 46.—This is one of the most common succulent euphorbias. It is easy to grow and prop. readily from cuttings, as well as from seeds which are frequently produced in cult. Several other species are in cult. under this name.

1445. *Euphorbia lactea*. No. 23.

1444. *Euphorbia grandicornis*. (X  $\frac{1}{2}$ )

HH. Sides of branches concave to deeply grooved between the ribs, which are more or less winged; branches 2-6 in. thick. (The species of this group and several others, e. g. *E. tenebrosa*, N. E. Br., *E. acurensis*, N. E. Br., *E. grandis*, Lem. (*E. neutra*, Berger), *E. controversa*, N. E. Br., *E. Erythraea* N. E. Br., are in cult., probably some in Amer., as *E. abyssinica* or some as *E. candelabrum*. The true *E. abyssinica*, Gmel., is not in cult.)

32. *neglecta*, N. E. Br. (*E. abyssinica*, Berger, not Gmel.). Tree: branches 5-8-angled, joints 4-12 in. long, 4-5 in. thick, the conspicuous wings marked by swollen veins; spine pairs 1 in. apart, sunken; spines stout, brown, 1-2 lines long; lvs. narrow, 1 in. or more long; flowering eye above the spine-shield. N. Afr. G.C. III. 20:497. Gn. 52, p. 106.

1446. *Euphorbia meloformis* ( $\times \frac{1}{2}$ ). No. 44.

shorter; spines darker; veins in wings not prominent. Natal(?).

34. *disclusa*, N. E. Br. (*E. candelabrum*, Berger, not Trem., see No. 24). Tree, with 4-5-angled st. and branches, slightly jointed; spine pairs 8-10 lines apart; spines 3-5 lines long, stout, dark brown to gray; flowering eye included in the spine-shield. Abyssinia.

FFFF. Angles of branches 9-13.

G. Spine-shields almost always united into a horny margin; grooves between ribs rather shallow; branches about 2 in. thick.

35. *Beaumierana*, Hook. & Coss. A shrub to 9 ft. high; branches erect, 9-10-angled; spines short, spreading, red when young. Morocco. J.H. III. 59:627.

36. *officinarium*, Linn. Shrub; branches 9-13-angled; spines but little spreading, yellowish to gray, 3-6 lines long; lvs. minute. N. Afr. R.H. 1875, pp. 336-7.

GG. Spine-shields often isolated; grooves between ribs very deep.

37. *fruticosa*, Forsk. Low shrub; branches erect, scarcely jointed, 6-9 lines thick, 10-13-ribbed; spines 6-9 lines long, spreading, brown when young. Arabia.

38. *Pfersdorffii*, Hort. Trunk round,  $1\frac{1}{2}$ -2 $\frac{1}{2}$  in. thick, 9-angled, much branched when old; spines large, 4-9 lines long.—A species not very well known.

DD. Spines, if any, not in stipular position. Subsection TREISIA.

E. Podaria in longitudinal rows or ribs.

F. Body cylindrical: sterile infl. transformed into thorns. CLASS ANTHACANTHA.

G. Ribs without prominent cross furrows between podaria.

39. *heptagona*, Linn. St. 3-4 ft. high, over 1 in. thick, candelabraform-branched, 5-8-ribbed; ribs broader than high; thorns not numerous, strong, yellow,  $\frac{3}{4}$  in. long; lvs. linear-lanceolate, acute. Cape of Good Hope.—According to N. E. Brown the plants of this section and their names are much confused in cult. and without careful study it would be difficult to say just what is being grown under the names of *E. heptagona*, *E. mammillaris*, *E. enopla*, etc.

40. *cereiformis*, Linn. (*E. enneagona*, Haw.). St. erect, 2-3 ft. high; branches with 9-13 straight ribs, the podaria forming declined teeth: lvs. small, triangular;

thorns numerous, 4-7 lines long. Cape region.—Cultings from the branches have a different form from seedlings.

41. *polygona*, Haw. St. up to 5 ft. high, 5 in. thick, 10-13-ribbed, the ribs high and narrow, often somewhat spiral; thorns 4-5 lines long; lvs. minute. Cape region.

GG. Ribs with the podaria separated by cross furrows.

42. *mammillaris*, Linn. Low: branches 7-12-ribbed, about 1 in. thick; ribs flat; podaria not prominent; zones of spines up to 1 in. long, alternate with areas free from them. Cape region. Var. *spinösior*, Berger, is more vigorous and spiny, with more prominent podaria.

43. *submammillaris*, Berger. St. irregularly branched, 1 in. thick; branches with about 5-8 straight ribs, 2 lines high; podaria forming pointed tubercles: lvs. linear; thorns numerous on strong branches, few on others. Cape region(?).—Grown as *E. mexicana*, *E. imbricata*, and *E. cereiformis*.

FF. Body spherical, not thorny.

44. *meloformis*, Ait. MELON SPURGE. Fig. 1446. Globose or pyriform, 3-5 in. thick, deeply 8-10-ribbed; ribs obscurely tuberculate on the almost acute angles; sides transversely dark and light green-striped, or wrinkled when old; lvs. few and small: fls. at the depressed apex; the old forked branches of the infl. sub-persistent but not spinose. A few small branches similar to the main st. present. S. Afr. L.B.C. 5:436. A.G. 11:463.—A curious and rare plant, often mistaken for a cactus and showing extreme reduction in xerophytic euphorbias as *Mammillaria* does for the cacti.

EE. Podaria in spirals checkering the axis.

F. Joints or branches globose to short-cylindrical: glands of the involucre with lobed or comb-like edges. See also No. 51. CLASS DACTYLANTHES.

45. *globosa*, Sims (*E. glomerata*, Hort.). Low, the spherical or short cylindrical to club-shaped joints crowded, forming a clump near the ground; joints

1447. *Euphorbia Lathyris*, young plant seen endwise. No. 52

$\frac{1}{2}$ -2 in. long; podaria very flat, pentagonal: lvs. very small, triangular: peduncle 2-4 in. long; glands of involucre with 3-4 lobes which are green with white pits; flowering all summer. Cape region. B.M. 2624.

46. *ornithopus*, Jacq. Much-branched half-shrub: joints 1 in. or less thick, short-cylindrical; podaria

elongated into conical projections: lvs. small ovate: peduncles short; fls. much as in *E. globosa*, involucre glands erect, the 3-4 teeth pitted and white-marked. Cape region. B.M. 2520. L.B.C. 3:220 (as *E. anacantha*).

47. *anacantha*, Ait. Cespitose sub-shrub, with some joints 4-8 in. long,  $\frac{3}{4}$  in. thick: podaria oblong, somewhat projecting: lvs. small, ovate-oblong; cyathia almost sessile at apex of branches; glands divergent, the 3-lobes white with greenish pits. Cape region.

FF. Joints of the branches obscure or none; branches cylindrical, many times as long as thick.

3. Sinuous or snake-like branches many, from a thick basal st.; thorns none: lvs. small; glands comb-like. Class MEDUSA.

48. *Câput-Medusæ*, Linn. (*E. Commelini*, DC.). MEDUSA'S HEAD. Branches 1-2 in. thick, numerous, declined about the short, obconical st., with ends erect, 6-12 in. long: lvs. linear-lanceolate, about 1 in. long: cyathia single, from short, thick peduncles; glands erect, white. Cape region.—A curious and interesting plant; often seen as single-stemmed plants grown from branch cuttings. *E. parvimamma*, Boiss., is also in cult. under this name. See Suppl. list.

49. *inermis*, Mill. (*E. viperina*, Berger, fide N. E. Br. *E. serpentaria*, Hort.?). Smaller: branches about  $\frac{1}{2}$  in. thick, 12 in. long; podaria narrow, in 6-8 somewhat spiral rows: lvs. very small, ovate; cyathia  $\frac{1}{2}$  in. wide, whitish, glands divergent. Cape region. B.M. 7971.

GG. Sinuous or snake-like branches none; glands simple, flat, without divided appendages: lvs. usually large; cyathia usually long peduncled, subtended by several broad bracts. Class TREISIA.

50. *loricata*, Lam. (*E. Hystrix*, Jacq., fide N. E. Br.). A shrub, 2-3 ft. high: branches divergent from the base,  $\frac{1}{2}$  in. thick: lvs. linear, 2-3 in. long: peduncles persistent as numerous brownish red thorns. Cape region.—Some species of the subsection Anthacantha are in cult. under the name of *E. Hystrix*. The names *E. clava*, Jacq., and *E. coronata*, Thunb., are used in the trade and belong to closely related if not identical species of S. Afr., probably not in cult. The sts. are smaller and the infl. less spinose than in *E. loricata*.

51. *bupleurifolia*, Jacq. St. ovate-spherical, elongated in age, 3 in. thick, 4-5 in. high: podaria scale-like, imbricated, quadrangular: lvs. at st. apex, 4-8 in. long,

1448. *Euphorbia epithymoides*. No. 57.

nearly sessile cyathia is listed, probably erroneously, in the trade.

BBB. Sts. herbaceous or woody, rarely somewhat fleshy, not spiny: infl. umbellate: stipules none. Section TITHYMALUS.

c. Lvs. below the umbel decussate: tall annual herb.

52. *Lathyris*, Linn. CAPER SPURGE. MOLE PLANT. Fig. 1447. Annual, 2-3 ft. tall: lvs. long, lance-linear, those of the infl. ovate-acuminate: glands short-

horned: caps. somewhat fleshy,  $\frac{1}{4}$ - $\frac{1}{2}$  in. diam. Eu., and naturalized in E. U. S. Rept. Mo. Bot. Gard. 11, pl. 11.—Cult. in old gardens. Caps. sometimes pickled, seeds used as a purgative. Said to drive away moles from its neighborhood (see Cornell Bull. 61:331); for a similar reason known as "gopher plant" in S. Calif.

cc. Lvs. usually clustered at ends of branches: shrubs. (*Euphorbia dendron*, Millsp.).

53. *atropurpurea*, Brouss. Branching shrub, 3-6 ft. high: lvs. pale, glaucous green, spreading or drooping, 2-3 in. long: umbel 5-10-rayed; cyathia surrounded by large, dark purple, broadly ovate, obtuse, connate bracts; glands ovate. March. Teneriffe. B.M. 3321.—Some other red-leaved species used for bedding in Amer. have been cult. under this name, i.e., a purplish variety of *E. pulcherrima*, and possibly *E. hama-todes*, Boiss.

54. *Régis-Jubæ*, Webb. Like the last but lvs. narrowly linear and bracts almost yellow: involucre glands with 2 short horns. Teneriffe.—Some plants under this name are *E. piscatoria*, Ait. See Suppl. list.

55. *dendroides*, Linn. A large branching shrub, more foliaceous than the two preceding: lvs. linear-lanceolate, obtuse or acute: bracts yellowish, rhomboid-orbicular mucronate; glands truncate or semi-lunate. Medit. region. Gn. 36, p. 203. R.H. 1887:160.

56. *fúlva*, Stapf (*E. elástica*, Altam. & Rose). PALO AMARILLO. Small tree: lvs. lanceolate, acute, pubescent: cyathia few, bracts small, glands ovate: caps. conical, 1 in. long. Mex.—Used for rubber.

ccc. Lvs. below the umbel alternate: leafy perennial herbs.

d. Glands of the involucre oval, entire.

57. *epithymoides*, Jacq. (*E. polychroma*, Kern.). Fig. 1448. Many sts. 1 ft. or more long, forming a hemispherical clump: rays of umbel 5: lvs. oblong, dark green, those of the infl. various shades of yellow at flowering time. May. Eu. B.M. 2258. Gn. 69, p. 295.—A beautiful plant for the formal or informal border.

58. *pilosa*, Linn. Sts. about 18 in. high from a thick rootstock, pilose: lvs. oblong, nearly entire: umbel 5-6-rayed, with similar branches below: caps. 2 lines broad, nearly smooth or hairy, with or without minute warts. Eu. and N. Asia. Var. *major* is a better form for gardens with beautiful golden yellow foliage.

59. *palustris*, Linn. Differs from *E. pilosa* chiefly in being glabrous or nearly so, more rays in the umbel, and caps. with small but distinct warts on the back. Eu. Gn. 76, p. 499.—The floral lvs. are a bright yellow.

DD. Glands of involucre truncate, retuse, 2-horned or crescent-shaped.

E. Seeds smooth.

60. *Cyparissias*, Linn. CYPRESS SPURGE and many local names. Fig. 1449. Many short plume-like branches from the crowns and adventitious root-buds, covered with spreading, narrowly linear, dark green lvs. 1 in. long. Eu. L.B.C. 2:118. G.C. II. 22:469. Rept. Mo. Bot. Gard. 11, pl. 50.—Cult. in old gardens and cemeteries for its moss-like growth. Naturalized and a weed in E. U. S., but rarely producing seed here.

1449. *Euphorbia cyparissias* ( $\times \frac{1}{4}$ ). No. 60.

61. *Wulfenii*, Hoppe. Sts. 3-4 ft. high, forming a clump, densely covered with lanceolate, linear, acute, bluish green pubescent lvs., those of the infl. yellow, or the base of the st. bare later, except for the conspicuous leaf-scars: umbel many-rayed; glands 2-horned. Eu. B. R. 24:6 (as *E. Veneta*). G. 31:103. G.C. III. 39:331. Gn. 57, pp. 440-1; 74, p. 40. G.W. 13, p. 305.

62. *biglandulosa*, Desf. Differs from *E. myrsinites*, chiefly in the erect sts., lanceolate, acute lvs. and smooth seeds. Sicily to Syria. B.R. 274 (as *E. rigida*).

EE. Seeds rugose or pitted.

63. *pinea*, Linn. St. glabrous: st.-lvs. linear; those of the infl. reniform-cordate: rays of umbel 5-7. Eu.

64. *robusta*, Small, and *Pálmeri*, Engelm., are many-stemmed desert plants from W. U. S., about 1 ft. high with small ovate lvs., irregularly crescent-shaped glands and roughened seeds. Rept. Mo. Bot. Garden. 11: pls. 40, 49.—They have been offered for sale, but have little cultural value.

65. *myrsinites*, Linn. The many declined sts. covered with large, fleshy, glaucous, obovate-oblong, concave, pointed lvs. in close spirals: umbel 7-12-rayed; glands and fls. yellow: seeds rugose. Eu.—A plant of old gardens; good for walls and rockeries.

The following have been reported in cult. in Eu. but are not in the American trade.

*E. aggregata*, Berger. A succulent grown like *E. cereiformis*.—*E. aleppica*, Linn. Annual of Tithymalus section.—*E. amygdaloides*, Linn. Perennial and almost woody. Common in England.—*E. angularis*, Klotzsch (E. fimbriata, Hort.). A 3-5-angled succulent.—*E. aphylla*, Brouss. Semi-succulent shrub, near *E. Tirucalli*. Gt. 37:277.—*E. arbuscula*, Balf. Semi-succulent shrub near *E. xylrophyloides*.—*E. balsamifera*, Ait. Tropical shrub; lvs. at end of branches. Allied to *E. dendroides*.—*E. Berthelotii*, C. Bolle. Subtropical shrub allied to *E. Regis-Jubæ*; name used incorrectly in 'he trade.—*E. Böjeri*, Hook. (E. Breonii). Semi-succulent, slender, spiny shrub near *E. splendens*, Hook. B.M. 3527.—*E. bubalina*, Boiss. (Section Treisia). Low, slender, spineless succulent, leafy at apex. R.B. 209 (as *E. oxystegia*).—*E. Cactus*, Ehrenh. Succulent, spiny 3-angled shrub, near *E. Hermentiana*.—*E. cattimandoo*, Ell. Small, succulent, spiny, 5-angled tree.—*E. cervicornis*, Boiss.—*E. hemata*.—*E. chamasce*, Linn. Low, opposite-lvd. herb with corolla-like cyathia in clusters.—*E. characias*, Linn. Umbellate perennial herb near *E. Wulfenii*. Gn. 59, p. 447. G.C. II. 13:657.—*E. collettoides*, Benth. Low Mexican shrub: lvs. opposite. Plants grown under this name may be *E. pteroneura*.—*E. Dinteri*, Berger. Spiny, 6-8-angled succulent shrub often grown under names of *E. virosa* and *E. tetragona*.—*E. Dregeana*, Mey. Spineless, almost leafless shrub, near *E. Tirucalli*.—*E. enopla*, Boiss. Spiny succulent near *E. heptagona*, and confused with it.—*E. erosa*, Willd. Spiny succulent, near *E. mammillaris*.—*E. falcata*, Linn. Annual herb, near *E. Aleppica*.—*E. fimbriata*, Hort.—*E. angularis*.—*E. hamata*, Sweet (E. cervicornis, Boiss.). Low succulent shrub, leafy at apex, near *E. clandestina*.—*E. helicothle*, Lem. Spiny, succulent tree, leafy at apex, near *E. nerifolia*. I.H. 4, p. 100, desc.—*E. helioscopia*, Linn. Umbellate annual (Section Tithymalus). Rept. Mo. Bot. Gard. 11: pl. 26.—*E. Intisy*, Drake. Semi-succulent tropical shrub, near *E. Tirucalli*.—*E. Lagasce*, Spreng. Annual, near *E. pilosa*.—*E. Laro*, Drake. Semi-succulent shrub near *E. Tirucalli*.—*E. lavrifolia*, Juss. Tropical shrub, leafy at ends of branches, near *E. atropurpurea*.—*E. Ledienii*, Berger. Spiny succulent, near *E. virosa*, grown under the names of *E. pentagona*, *E. cœrulea*, and *E. cœrulescens*. B.M. 8275.—*E. Lemaireana*, Boiss. Spiny succulent. Near *E. grandicornis*.—*E. lophogona*, Lam. Succulent with fringed angles, near *E. Fournieri*. B.M. 8076.—*E. macroglypha*, Lem. Spiny, 3-angled succulent.—*E. Marlothii*, Pax.—*E. Montieri*.—*E. mauritanica*, Linn. Semi-succulent shrub. Near *E. Tirucalli*.—*E. mellifera*, Ait. Tree, leafy at branch ends. Near *E. dendroides*. B.M. 1305.—*E. Montieri*, Hook. (E. Marlothii, Pax). Succulent shrub, leafy at the apex, of Section Pseud-euphorbium. B.M. 5534.—*E. Morinii*, Berger. Spiny succulent, near *E. cereiformis*.—*E. multiceps*, Berger. Succulent. Near *E. Caput-Medusæ*.—*E. nivida*, Ham. Spiny, succulent shrub, leafy at apex. Near *E. nerifolia*.—*E. Nykæ*, Pax. Succulent tree with 2-angled joints.—*E. obesa*, Hook. Succulent. Near *E. meloformis*. B.M. 7888.—*E. obtusifolia*, Poir. Semi-succulent shrub. Near *E. Tirucalli*.—*E. officinarum*, Linn. Succulent, spiny, 9-13-angled shrub. Near *E. Beaumieriana*.—*E. Paralias*, Linn. Perennial herb of Section Tithymalus.—*E. parvimamma*, Boiss. Low succulent, without spines. Near *E. Caput-Medusæ*.—*E. Phillipsia*, N. E. Br. Succulent, spiny, 9-angled shrub. Near *E. Beaumieriana*.—*E. pilulifera*, Linn. Low annual with opposite lvs. and inconspicuous cyathia in clusters: glands appendaged.—*E. piscatoria*, Ait. Tropical shrub: narrow lvs. at end of branches. Near *E. Regis-Jubæ*.—*E. plumerioides*, Teymann. Tropical shrub similar to the previous one.—*E. procumbens*, Mill. (E. pugniformis, Boiss.). Succulent, not spiny. Near *E. Caput-Medusæ*. B.M. 8082. R.B. 161.—*E. punicea*, Swartz. Tropical shrub. Near *E. atropurpurea*. B.R. 190. B.M. 1961. L.B.C. 20:1901. G.C. II. 15:529.—*E. pyrifolia*, Lam. Semi-succulent shrub, leafy at the apex.

Near *E. lophogona*.—*E. Sappinii*, De Wild. Slender, spiny succulent. Near *E. cereiformis*. G.C. III. 45:66.—*E. Schimperii*, Presl. Semi-succulent shrub. Near *E. Tirucalli*.—*E. Schimperiana*, Hochst. An African annual of Section Tithymalus. This name perhaps used erroneously for *E. Schimperii*.—*E. Scolopendria*, Don.—*E. stellata*.—*E. scopiformis*, Boiss.—*E. serpylliformis*.—*E. serpylliformis*, Boiss. Section Anthrothamnus. Slender-branched semi-succulent shrub with opposite, rudimentary lvs.—*E. Sib-sim-succulent* shrub with opposite, rudimentary lvs.—*E. Sib-sim-succulent* herb. Near *E. Wulfenii*.—*E. Sipoltsii*, thornii, Boiss. Perennial succulent shrub with decurrent lf.-bases. N. E. Br. Slender succulent shrub with decurrent lf.-bases. Near *E. pteroneura*.—*E. spinosa*, Linn. Umbellate sub-shrub or herb of S. Eu. Section Tithymalus.—*E. stapeliiformis*, Hort.—*E. stapelioides*, Boiss. (?) A plant near *E. bupleurifolia*.—*E. Stäpfi*, Berger. Spiny, succulent, 4-angled shrub.—*E. stel-læspina*, Haw. Spiny 10-13-ribbed succulent. Near *E. cereiformis*.—*E. stellata*, Willd. (E. uncinata, DC., referred here according to N. E. Br.). Spiny succulent with branches V-shaped in cross-section, and clustered on a short thick st.—*E. tetragona*, Haw. Spiny, succulent 4-angled tree. R.B. 39.—*E. trigona*, Haw. Spiny, succulent, 3-angled shrub, near *E. antiquorum*.—*E. tuberculata*, Jacq. Low succulent, near *E. Caput-Medusæ*.—*E. uncinata* —*E. stellata*.

Other names used but not classified: *E. Amélia*, Hort.—*E. articulata*, Hort.—*E. aurélia*, Hort. (E. Amélia?).—*E. Caput Comelini*, Hort. (E. Caput-Medusæ?).—*E. Caput-odorata*, Hort.—*E. Caput-Simie*, Hort.—*E. capensis*, Hort. (succulent).—*E. colubrina*, Hort.—*E. cylindrica*, Hort.—*E. dentata*, Hort.—*E. de Smetiana*, Hort.—*E. erecta*, Hort.—*E. funalis*, Hort.—*E. gardeniaefolia*, Hort.—*E. gracilis*, Hort.—*E. Houlettiana*, Hort.—*E. Houlettii*, Hort.—*E. longifolia*, Hort.—*E. mangador*, Hort. (E. mogador, Hort.?).—*E. Milleri*.—*E. obtusa*, Hort.—*E. pavoensis*, Hort.—*E. pulchra*, Hort.—*E. Pulletiana*, Hort.—*E. Rebütii*, Hort.—*E. sahariensis*, Hort.—*E. waltoniensis*, Hort.

J. B. S. NORTON.

**EUPHORIA** (name refers to the fact that the plant carries well its edible frs.). *Sapindaceæ*. A half-dozen trees in Trop. and Subtrop. Asia, allied to Litchi but differing in having petals and a deeply 5-parted imbricate calyx; both genera are sometimes combined in *Nephelium*. Lvs. pinnate: fls. regular; petals spatulate or lanceolate, hairy inside; stamens usually 8: fr. globular or ellipsoid, more or less tuberculate or warty, the size of a cherry or plum. The following species is widely cult. in the eastern tropics. *E. Longana*, Lam. (*Nephelium Longana*, Cambess.). Tree, 30-40 ft., with gray bark: lvs. scattered; lfts. opposite or alternate, elliptic to ovate to lanceolate, 2-5 pairs, rather obtuse at both ends, to 12 in. long, entire: fls. small ( $\frac{1}{4}$  in. or

1450. Leaves of *Euphorbia polyandra*. ( $\times \frac{1}{2}$ )

less across), yellowish white, in puberulent terminal and axillary panicles; calyx deeply 5-6-lobed; petals about equaling calyx, spatulate; fr. globose, reddish or purple,  $\frac{3}{4}$  in. or less diam., tuberculate or becoming warty or nearly smooth, with an edible aril. India. B.M. 4096. B.R. 1729.—A much-prized fr. in China, under the name of longyen, or linkeng, resembling litchi but smaller and smoother and yellow-brown.

L. H. B.

**EUPHRASIA** (Greek for *hilarity* or *delight*). *Scrophulariaceæ*. EYEBRIGHT. More than 100 low herbs, of no special horticultural value although some of them are mentioned in connection with alpine-gardening. They are more or less parasitic on roots of other plants: lvs. opposite, dentate or incised; fls. small, largely whitish or purplish, in terminal leafy spikes; calyx mostly 4-cleft; corolla 2-lipped; stamens 4, didynamous, ascending under the upper lip; caps. oblong, many-seeded, dehiscent. The species range in temperate and cold parts of the globe, several of them being N. American.

**EUPTELEA** (Greek *eu*, well, handsome, and *ptelea*, elm). *Trochodendraceæ*. Ornamental woody subjects grown for their handsome foliage; also the red anthers of the precocious flowers are conspicuous in early spring.

Deciduous shrubs or small trees: winter-buds conspicuous, with imbricate dark brown scales; lvs. alternate, slender-petioled, dentate; fls. before the lvs., in axillary clusters along last year's branches, perfect, without perianth; stamens many, with large oblong-linear, red anthers; carpels many, stipitate, oblique, with a decurrent stigma, developing after the stamens have dropped, growing into a small, slender-stalked obliquely winged 1-4-seeded nutlet.—Three species in Japan, Cent. and W. China, and E. Himalayas.

They are graceful bushy trees resembling the linden in habit and foliage; the bright green leaves are very slender-stalked, and the tree is conspicuous in early spring from the bright red anthers of its flowers. *E. polyandra* has proved hardy at the Arnold Arboretum and possibly *E. Franchetii* is of the same hardiness. They seem to grow well in a loamy well-drained soil and prefer somewhat moist situations. Propagation is by seeds or by grafting on their own roots.

*polyandra*, Sieb. & Zucc. Figs. 1450, 1451. Shrub or small tree, to 20 ft.: lvs. long-petioled, usually roundish ovate, cuspidate, coarsely and irregularly dentate, below pale green and slightly pubescent on the veins, 2-4 in. long; carpels usually 1-seeded,  $\frac{1}{2}$  in. long. April. Japan. S.Z. 72. S.I.F. 1:41. Gng. 16:162.

*Franchetii*, Van Tieghem (*E. Davidiana*, Hemsl., not Baill.). Tree, to 40 ft.: lvs. long-petioled, usually roundish-ovate, cuspidate, fairly regularly sinuate-dentate, light green below, 2-4 in. long; carpels usually 2-3-seeded. April. Cent. and W. China. H.I. 28:2787. V.F. 9.

*E. pleiosperma*, Hook. f. & Thoms. (*E. Davidiana*, Baill.). Closely related to *E. Franchetii*. Lvs. glaucous below; carpels somewhat larger. W. China, E. Himalayas.

ALFRED REHDER.

**EURYA** (Greek for *large*, but of no application). *Ternstroemiaceæ* (or *Theaceæ*). Shrubs of S. Asia and Malaya (30 or more species), with small diocious fls., berry-like frs., and simple, glabrous evergreen lvs.: fls. in axillary clusters, or rarely solitary; petals and sepals 5; stamens 15 or less (rarely only 5), joined to the base of the corolla; ovary usually 3-loculed. *Cleyera* is by some included in this genus. The euryas are allied to camellias, and require much the same treatment. They are grown for foliage rather than for fls. They require an intermediate temperature and a peaty soil. Prop. by cuttings taken from the tips of growing shoots. *E. japonica*, Thunb. (*E. Sieboldii*, Hort.), is the common species, and is very variable. The variegated form

of it (known in the trade as *E. latifolia variegata*) is one of the best glasshouse decorative pot shrubs: lvs. variable in shape, usually ovate-acuminate and irregularly toothed or notched, short-petioled, variously blotched with white; fls. greenish white, in small, axillary clusters. Japan. V. 23:5.

L. H. B.

**EURYALE** (mythological name). *Nymphæaceæ*. One species, the Indo-Chinese representative of *Victoria*

1451. Flowers of  
*Euptelea polyandra*.  
(Natural size.)

*regia*, from which it differs in having all the stamens fertile (in *Victoria* the inner ones are sterile) and in the very small fl. and in other technical characters. *E. ferox*, Salisb., is the species. The lvs. are 1-4 ft. across, circular, purple and spiny-ribbed beneath, dark green and uneven above; fls. about 2 in. broad, open by day, prickly outside; calyx reddish inside and the 20-30 purple petals shorter than the calyx-lobes; stamens numerous; fr. a small many-seeded, globular berry, bearing the remains of the calyx on its top; seeds edible. B.M. 1447.—Long cult. in China. Treated as an annual. Has attracted little attention since the intro. of *Victoria*. Prop. by seeds only, which are best stored in fresh cold water. Plant in rich earth as for nymphaeas, at 70-75° F. As far north as Philadelphia and St. Louis it is hardy, sowing itself every season. It is ferociously spiny.

*E. amazonica*, Poepp., still advertised in catalogues, is *Victoria regia*.

H. S. CONARD.  
WM. TRICKER.

**EURYANGIUM**: *Ferula*.

**EURYCLES** (Greek-made name, of no particular application). *Amoryllidaceæ*. Two south hemisphere tunicated-bulbous plants, allied to *Hymenocallis* and *Pancratium*. Fls. white or whitish, umbellate on peduncles 12-18 in. long; perianth-tube cylindrical, the segms. oblong-lanceolate, ascending and nearly equal; stamens inserted in the throat of the tube; lvs. broad and stalked, with prominent curving veins and interlocking veinlets. *E. sylvestris*, Salisb. (*E. amboinensis*, Loud.). BRISBANE LILY. Scapes 1-2 ft., bearing an umbel of 10-40 handsome, creamy white fls. (2 in. across); lvs. round-cordate, with a very short, blunt point; blooms in May and June in Eu., the lvs. appearing later. B.M. 1419 (as *Pancratium amboinense*). B.R. 715 (as *Pancratium australasicum*). R.H. 1879, p. 456 and p. 457 (as *E. australasica*); 1913, p. 111. G.W. 11, p. 583. G.Z. 24, p. 25. Malaya, Philippines, N. Austral.—Cult. apparently as for *pancratiums*.

L. H. B.

**EURYOPS** (*large eyes*, because of the prominent fls.). *Compositæ*. Small shrubs of 25-30 species of Afr. (mostly S. Afr.), Arabia and Socotra, very little known in horticulture. The fls. are yellow, the heads with female rays and tubular 5-toothed perfect disk-fls.; receptacle convex or conical; involucre of 1 series of scales: achene wingless and beakless, the pappus of several rows of caducous bristles. These little bushes or undershrubs grow from  $\frac{1}{2}$ -3 ft., or sometimes 5 ft.,

high. They are bloomed in the greenhouse or grown in the open in mild climates. None seems to be regularly in the trade.

**EÛSCAPHIS** (Greek, *eu*, handsome, and *scaphis*, vessel; alluding to the shape and the handsome color of the dehiscent capsule). *Staphyleaceæ*. Ornamental woody plant grown for its handsome foliage and the attractive fruits.

Deciduous upright shrub or small tree, glabrous: lvs. opposite, odd-pinnate, stipulate: fls. in terminal upright panicles, perfect; sepals, petals and stamens 5, all of nearly equal length; ovary 2-3-celled, surrounded at the base by an annular disk; styles 2-3, often connate: fr. consisting of 1-3 spreading, leathery dehiscent pods, each with 1-3 black seeds.—One species in Japan and Cent. China. A handsome plant with large pinnate lvs., small whitish fls. in upright panicles followed by attractive brownish red frs. disclosing shining black seeds when opening. It grows in any good garden soil, but is only half-hardy N. Prop. by seeds and green-wood cuttings under glass.

*japónica*, Dipp. (*E. staphyleoides*, Sieb. & Zucc. *Sambucus japónica*, Thunb.). Shrub, to 10 ft.: lfts. 7-11, ovate-lanceolate, glabrous, serrate,  $1\frac{1}{2}$ -3 in. long, each with 2 small stipules: fls. in broad many-fld. panicles to 6 in. long: fr. consisting of 1-3 pods,  $\frac{1}{2}$  in. long, apiculate, each with 1-3 steel-blue seeds. May, June; fr. Aug., Sept. Japan. S.Z. 67. S.I.F. 1:70.

ALFRED REHDER.

**EÛSTOMA** (good mouth, alluding to the corolla). *Gentianaceæ*. Two or 3 N. American large-fld. glaucous opposite-lyd. small herbs: fls. more or less paniculate, single on the peduncles, 5-merous or rarely 6-merous; calyx with narrow keeled lobes; corolla nearly campanulate, white, blue or purple, the lobes oblong or obovate, usually erose; stamens attached on the corolla-throat; ovary 1-celled; stigmas 2; caps. oval or oblong, many-seeded. *E. selenifolium*, Salisb. (*E. exaltatum*, Griseb.). Annual, but in S. Calif. said to be perennial, 9-15 in. erect: lvs. oblong, glaucous-green: fls. light blue or purple, the corolla-lobes about or nearly 1 in. long, twice exceeding the tube. Fla. to Calif. Offered in Calif.

**EÛSTREPHUS** (Greek, referring to the climbing habit). *Liliaceæ*. One or two Australian plants, botanically related to *Lapageria*, but much less showy; in habit suggestive of smilax (*Asparagus medeoloides*). Plants more or less woody at base, slender, branching, tall-climbing: lvs. alternate, sessile or short-petioled: fls. 2 to many, in axillary fascicles; perianth-segms. distinct and spreading; stamens 6. *E. latifolius*, R. Br., is a tall and much-branched half-twining herb, more or less woody at the base, bearing alternate, stiff, linear-lanceolate, short-stalked lvs. and small, axillary, drooping light blue fls. with spreading, ciliate perianth-segms.: fr. a dry berry: lvs. 2-4 in. long, sharp-pointed: fls. less than 1 in. across. B.M. 1245. Of easy cult., either in the glasshouse border or in pots. Very useful for table decoration and for design work.

L. H. B.

**EUTÁCTA:** *Araucaria*.

**EUTÁXIA** (from Greek words referring to the attractive appearance). *Leguminosæ*. Shrubs of Austral., with golden or yellow papilionaceous fls., one of which is offered for greenhouse cult.: lvs. small, opposite, simple and entire: fls. solitary or a few together, or sometimes crowded at ends of branches; standard orbicular, entire or nearly so, exceeding the other petals; stamens free; pod ovate, 2-valved. Said to require general treatment of *Chorizema*. *E. myrtifolia*, R. Br. Glabrous, 2-3 ft.: lvs. obovate-oblong to linear, mostly  $\frac{3}{4}$  in. or less long: fls. yellow with dark orange keel, solitary or 2-4 together. B.M. 1274 (as *Dillwynia*). R.B. 26:13. Var. *floribunda* is listed.

**EUTÉRPE** (mythological name). *Palmaceæ*, tribe *Arècæ*. Slender erect spineless palms, with solitary or fasciculate ringed caudices, and grown chiefly for their graceful habit and feathery pinnate foliage.

Leaves terminal, equally pinnatisect; segms. narrowly linear-lanceolate, long, and gradually acuminate or ensiform, membranaceous, plicate, the thickened margins recurved at the base; rachis and petiole 3-sided toward the base, convex on the back, concave above; petiole elongated; sheath very long, cylindrical, entire; spadix paniculately branched; rachis elongated: branches slender, gradually shortening above, usually scaly, thick at the base, erect-spreading in fl.: spathes 2, coriaceous or membranaceous, lanceolate, the lower one shorter, split at the apex, dorsally 2-keeled, the upper one symmetrical, split down the ventral side: bracts bordering the furrows; bractlets ovate-acute: fls. small, white, sessile in the furrows of the spadix: fr. like a pea, purple.—Species about 8. Trop. Amer. and W. Indies. G.C. II. 24:586.

Three species of *Euterpe* are commonly found in cultivation, namely: *E. edulis*, *E. montana* and *E. oleracea*. These are found under varying conditions in Central and South America and the West Indies, and all three species are valuable as food-producers to the natives of those countries. *E. edulis* grows in great quantities in the lowlands of Brazil, where it is known as the assai palm, owing to the fact that its seeds are macerated in water, and by this means is produced a beverage known as assai. *E. oleracea* is the well-known cabbage palm of the West Indies, growing in the lowlands near the coast, while *E. montana* is the mountain cabbage palm, and is frequently found at considerable altitudes in the same islands, and consequently does not attain the great dimensions of *E. oleracea*.—The euterpes do not present any special cultural difficulties, being free-rooting and rapid-growing palms; a night temperature of 65° F., and abundant moisture are among their chief requirements. A good turfy loam, with the addition of about one-fifth of stable manure while in the compost heap, provides a suitable soil. From their habit of forming a tall slender stem without suckering from the base, the euterpes are liable to become rather leggy specimens. When under cultivation, and for trade purposes, it is advisable to group three or four of the young plants together, thus producing a more bushy specimen. White scale is one of the worst pests to which these palms are subject, and soon ruins the foliage unless care is taken. Seeds germinate in a few weeks if sown in a warm greenhouse, and the young plants make better progress when moderately shaded. (W. H. Taplin.)

*edulis*, Mart. PARA PALM. ASSAI PALM. St. 60-90 ft. high, 8 in. thick, flexuous: lvs. 10-15, spreading; the lfts. often pendulous; sheaths 3-4½ ft.; petiole 1½ ft.; blade 6-9 ft.; segms. linear, spreading, deflexed, 60-80 on each side, densely crowded, 28-36 in. long,  $\frac{3}{4}$ -1 in. wide: spadix about 2-3 ft. long, bearing numerous rather inconspicuous fls. Brazil.

*oleracea*, Mart. CABBAGE PALM. St. 60-100 ft., scarcely 1 ft. diam. at base, attenuate above, flexuous: lvs. arcuate-spreading, 4-6 ft. long, the apex more or less deflexed; segms. pendent, linear-lanceolate, the upper 2 ft. long, 1 in. wide, many-nerved. Brazil. See *Oreodoxa*.

*montana*, R. Graham. St. 10 ft. high, swollen at the base, ringed: lvs. 9 ft. long, elliptical-obovate; segms. lanceolate, entire, glabrous, alternate; petiole 2 ft. long, scaly beneath, unarmed; rachis plano-convex below, subtriangular toward the apex: spadices several on the trunk at one time, axillary, much branched; fls. numerous, white. Grenada. B.M. 3874.—Intro. into Botanic Garden at Edinburgh in 1815.

JARED G. SMITH.  
N. TAYLOR.†

EUTOCA: *Phacelia*.

**EVAPORATING FRUIT.** The domestic operation of drying fruit has been practised ever since men looked beyond their immediate wants and stored food for time of greater need. Dried fruit has long been an article of commerce, yet until a few years ago only the most primitive methods were used in drying, and the industry, commercially, was confined to a few favored regions in Europe. The modern industry is not yet a half-century old. Its almost inconceivable growth in America in this brief time is one of the industrial phenomena of the times. Spurred into activity by the encroachment of American products in their markets, the European producers, by the adoption of better methods, and by governmental encouragement, have increased greatly their output of dried fruit. Thus, from an adjunct to fruit-growing for home use, drying fruit has become, within recent years, one of the main branches of horticulture.

An idea of the dried-fruit industry in the United States and of its great growth in recent years may be obtained from the following figures from the census of 1910 for the crop of 1909:

|                       |                           |             |
|-----------------------|---------------------------|-------------|
| Raisins.....          | 111,774,767 pounds, worth | \$4,837,933 |
| Prunes.....           | 138,498,490 pounds, worth | 5,130,412   |
| Peaches.....          | 46,843,391 pounds, worth  | 2,423,083   |

Adding the valuations given, results in a grand total of \$19,840,395 for dried fruits in the year 1909. Comparing this sum with the census of 1900, one finds that the crop in 1899 was valued at \$4,757,005 and that the industry, judged by the figures, has increased more than fourfold in ten years.

Fruit may be cured in the sun, or it may be cured in drying-machines, called evaporators. That cured in the sun is called by the producer "dried fruit," that in evaporators, "evaporated fruit." By far the larger part of the world's product is cured in the sun. Thus, at least three-fourths of the fruit dried in America is sun-dried in California.

*Sun-drying fruit.*—In countries having a sufficiently warm and dry climate, as Greece and Turkey, and parts of France, Spain and western America, fruit is dried almost wholly in the sun. The fact that in these favored localities the drying capacity is limited only by the acreage of sunshine, makes it certain that the proportion of sun-dried fruit will always be vastly greater than that of evaporated fruit. Drying fruit in the sun is a simple process, but one hedged in by many little arts and methods that facilitate the work and improve the product. In general, the process is as follows: The fruit is graded, bleached by sulfur, if a light-colored product is desired, in the case of prunes dipped or pricked, and is then spread on trays to be exposed to the sun. When the drying process is completed, the fruit is again graded, in most cases put through a sweat, and then "finished" in various ways, as by dipping or glossing.

*Evaporating fruit.*—There are many styles of evaporators, but all possess in common a chamber for the reception of the fruit, through which a current of warm air is forced, or the fruit is forced through the air, or both, the object being to remove the aqueous matter from the fruit as quickly as possible, and the principle being that warm air will absorb more moisture than cool air. The saturated air must not remain in contact with the fruit. Since different fruits exact different conditions, it is necessary to change the temperature and velocity of the air-current in the drying-chamber at will. To make the product homogeneous, current and temperature must be equal in all parts of the evaporator. It is obvious that simplicity in the machine and economy in heat and in room are cardinal virtues in a good evaporator. It is the rule to

start the evaporation of large fruits at a low temperature and finish at a high one, but with berries the reverse is true.

Recently two or three patented processes for curing fruit by "dehydration" have been introduced with much promise of betterment in the industry. While the machinery, the methods and the products are quite different in evaporating and dehydrating, the principle in the two operations is practically the same. In both processes the water is removed from the fruit by moving currents of warm air. In evaporation the air is warmed only. In dehydration the air is dried by cooling until the moisture is condensed out and is then warmed and passed over the fruit or vegetable to be cured. By the new process much time is saved and a greater variety of fruits and vegetables can be used.

The following are definitions of the somewhat technical terms used in the industry: *Bleaching* is the process of changing the dark color of fruit to a lighter hue, or of preventing the discoloration; it is generally accomplished by sulfuring. *Bloaters* are prunes which in drying swell up to an abnormal size; they are usually produced by fermentation in over-ripe fruit. *Chops* are dried apples cured without paring or coring to be used in making cider or vinegar. *Dipping* is the process of cutting the skin of fresh prunes to facilitate curing. The operation is performed by submerging the fruit in boiling lye. Cured fruit is sometimes dipped in one of various solutions as a "finishing" process. *Drip* is the syrupy liquid which oozes from prunes in the process of evaporation; it generally characterizes a poor prune or a poor evaporator. *Frogs* are cured prunes having an abnormal shape, a condition caused by curing unripe fruit. *Pricking* is the process of puncturing the cuticle of fresh prunes. It is done by means of a machine, the essential part of which is a board covered with projecting needles, over which the prunes must pass. It accomplishes the same end as lye-dipping. *Sizes* is a term used to indicate the number of cured prunes it takes to make a pound. The "four sizes" known in the markets are 60's-70's, 70's-80's, 80's-90's, 90's-100's. *Sugaring* is the formation of globules of sugar on the cuticle of cured prunes or raisins. *Sulfuring* is a process to which fruit is subjected to give it a lighter color. The fruit is exposed to fumes of burning sulfur before being exposed to the sun or put in evaporators. *Sweating* is a process to which cured fruit is subjected before packing; it is put in a room at a high temperature and allowed to become moist. *Waste* is a dried product made from skins and cores of apples and pears and used for vinegar.

Apples and pears are peeled, cored, cut into rings and bleached by being exposed to the fumes of sulfur for about a half hour in preparation for drying or evaporating. Fruits so prepared are placed upon trays for sun-drying and must be cured in the sun for three to five days. In evaporating in the western states, the prepared fruits are placed on trays and passed in from six to twelve hours through the evaporator chamber, but in the East, where the product is chiefly made, the prepared fruit is piled from 4 to 6 inches deep on the floor of a kiln. Here it is left for fourteen to sixteen hours, being turned every two or three hours, until the fruit is no longer sticky, an indication that it has reached the proper stage of dryness. In New York, the law requires that evaporated apples contain not more than 27 per cent of moisture. One hundred pounds of apples will yield from twelve to fifteen pounds of evaporated apples.

Apricots, peaches and nectarines must be fully ripe before drying and without bruises. They are pitted, and may or may not be peeled. If peeled, the operation is done with a machine or with lye, though the use of the latter is considered bad practice. The fruit is placed on the trays cup side up. About three days are required for drying in the sun and about eight hours

for evaporating. The cured product should be of a translucent amber color.

Berries are seldom sun-dried for the markets. For evaporating they are placed on trays in quantities of sixteen to thirty quarts, given a temperature of about 175° at the start, and are finished in four to five hours, at a temperature of about 100°. After being taken from the evaporator, they are piled for sweating in a warm, ventilated room.

1452. Where to dig in removing an evergreen.

Figs for drying must be gathered when fully ripe. Some growers prefer drying in shade rather than in sun. Evaporators are seldom used. The fruit is not allowed to dry hard, and before packing must be well sweated. Usually, for "finishing," they are dipped in salt water or syrup. The drying process requires from five to eight days.

Prunes are allowed to ripen until they fall to the ground. Before being spread on the trays they are dipped or pricked in order to thin or crack the skin, that the moisture may easily escape, and dripping be prevented. Sun-drying requires from one to three weeks, while from twelve to thirty hours are required for evaporation. A thorough sweat prevents the sugaring so common to this fruit. Before packing they are graded in sizes. Dipping as a "finishing" process is practised by many producers. A good prune is soft, smooth and meaty, with loose pit, and of an amber, dark red or golden hue, depending upon the variety.

Grapes for raisins are sun-dried. They must be picked when fully ripe, the bunches, and the berries on the bunches, being sorted as the picking progresses. The operation of drying must be watched with care. The process requires from eight to fourteen days, during which time the bunches must be turned at least once. A sweat is given before packing. Raisins are graded into half a dozen or more brands for the market.

U. P. HEDRICK.

**EVERGREENS.** In horticulture, evergreens are plants that retain green foliage the year around; they do not shed all their foliage at any one time; in some cases, the individual leaves may remain attached and green for some years, as in many of the Coniferae, but in all evergreens the old leaves shed after a time when they become so overshadowed or crowded as to be no longer functional. The leaves of pines and spruces may persist three to fifteen years.

In the popular mind, "evergreen" and "conifer" are synonymous; but some conifers—as the taxodiums and larches—are deciduous. Moreover, in the tropics very many trees aside from conifers are evergreen, as notably the palms.

Evergreens may be classified as coniferous and broad-leaved, the latter including such plants as rhododendron, kalmia, mahonia, box and many others. The number of plants that are evergreen in the latitude of New York City is very large. Few persons recognize the wealth of good winter greenery that may be secured by exercising careful choice of material and providing proper conditions

1454. The roots bound up, and tree being loaded.

and protection for its growth. There are many very low evergreen plants that may contribute much to the winter interest of a yard or garden, in the way of edgings, masses, rosettes, and ground cover. The following lists indicate the materials that are now at the command of the planter.

Beyond the latitude of Lake Erie, the dependable evergreens are mostly conifers. At the Central Experimental Farm at Ottawa, those deciduous plants that hold their foliage fairly late in the autumn are mostly too tender for use. A few good plants, however, are, Oregon grape (*Mahonia*), bearberry (*Arctostaphylos Uva-ursi*), *Pachysandra terminalis*, shrub yellow-root (*Xanthorrhiza aptifolia*), and *Quercus imbricaria*. The Oregon grape is perhaps the most useful evergreen there for ground-covering. The hardier species of *Ligustrum* are also fairly satisfactory, but most of the species of this genus leave so much dead wood after winter that in very large masses they are liable to be unsightly. Many attractive conifers are reliable at Ottawa, in the genera *Abies*, *Chamaecyparis*, *Ginkgo*, *Juniperus*, *Picea*, *Pinus*, *Pseudotsuga*, *Taxus*, *Thuja*, *Tsuga*.

The uses of evergreens are discussed in other places in the Cyclopaedia, as under *Arbiculture*, *Herbary*, *Landscape-Gardening*, *Lawn-Planting*, *Perennials*, *Rock-Gardening*, *Screens*, *Shrubbery*, *Topiary Work*, *Wild-Garden*, *Windbreaks*, *Winter-Gardening*. For lists of evergreens for California, see pp. 379-381 (Vol. I).

1455. The method of binding up the roots.

1453 Digging up an evergreen.

#### Moving large evergreens.

Figs. 1452-1457.

Large evergreens are moved with a ball of earth because they have no dormant period, but carry their foliage and need moisture at all times of the year. It is essential that the ball of earth contains a sufficient amount of small fibrous feeding roots to support the tree and that the tree be kept well watered for two or more seasons until the tree has spread its roots over sufficient area to gather enough rainfall to sustain the normal growth. The extent of fibers in the ball is increased by transplanting and root-pruning. Root-pruning is less essential with trees having an abundance of fibrous roots than with trees having only a few large coarse roots in the central portion. Some trees, as white pine, will survive with a comparatively small number of roots, their drought-resistant qualities enabling them to persist with a small supply of moisture. Other evergreens, as Nordmann's fir, have a long carrot-like taproot, and the tree is likely to die if this is cut and the tree given an inadequate quantity of water. Frequent nursery transplanting is, therefore, necessary with this species.

Trees are dug by starting a trench at a radius from the tree about 3 feet wider than the ball of earth to be taken. The roots are cut off on the outside of the trench and the soil dissected out from between the roots back to the size of the ball. These roots are bent around against the ball of earth if they are

1456. Digging the hole in frozen ground to receive the tree.

flexible enough to bend. If not sufficiently flexible and tractable, they are cut off.

A canvas is made 15 to 24 inches deep, and is made smaller at the bottom by folding over a V and sewing it. This makes it fit a conical ball and, when it is pulled up 3 inches by the cross-lashing at the top, makes it tighter. The canvas has cross-ropes sewed on it with rings at the top and bottom, and on the deeper balls two rows of rings in the middle. The bottom rope is tightened by a wooden lever 20 inches long with four holes, the rope being looped through the holes and the lever thrown over to pull the rope tight. The top rope is then tied and tightened by cross-lashing.

To get the ball free from the subsoil, dig under all around and tip the tree slightly. Level off the bottom with a fork. If there are tap-roots, tunnel under and cut them with a saw. Put a platform as far under as possible and tip the tree back. To get the ball in the center of the platform, put a hammock around the ball and pull. Hold the platform in position by crowbars driven in front of it. Lash the ball to the platform, make an incline, drag the platform out of the hole onto a truck or sled. Skids with small wheels set in them about 1 foot apart enable a team to load a ball quickly. With balls 10 to 15 feet in diameter and 20 inches deep, jacks and pipe rollers are needed.

1457. Transporting a large evergreen tree.

Trees over 10 feet need to be tipped over to go under wires. If the canvas is put on tight and at the proper taper, and if the ball is cut flat to fit close to the platform and lashed tight to the platform, the tipping can be done without the ball shaking loose. Sometimes a canvas or burlap bottom can be put between the platform and the ball. In unloading, the tree is stood up, team hooked to the platform and the tree dragged off to the ground. The tree may drop 2 feet without injury. The platforms are dragged to the hole and balls less than 4 feet rolled into the hole. Larger balls have the platform dragged into the hole and the platform pulled out holding the tree in position by a hammock. To straighten the tree, tramp the earth solid under it until it stands erect. Take off the canvas, spread out the side roots, pack the earth and anchor as with deciduous trees. Keep the ball moist; examine it once a month or more often by digging or boring into the ball during the first two years. Evergreens moved with a too small ball or with not enough fibers in the ball or with the watering neglected, may grow 3 inches a year for the first two or three years. If properly moved, they will grow 6 inches or more a year—half their normal growth.

Deciduous trees may be moved with balls of earth by the above method, and it has proved an aid with difficult species, as beech, oak, liquidambar, tulip. Especially when previously transplanted or root-pruned, the above trees  $3\frac{1}{2}$  inches in diameter moved with a ball of earth 4 feet in diameter are very success-

ful, while without a ball many are lost or the growth is much slower. Investigation should be made to see whether this is because of less disturbance of the roots or because there is carried with the roots and soil a mycelium of a fungus which aids the roots to take up plant-food and moisture.

The time of year for moving trees is of minor importance. It is over-emphasized by purchaser, landscape architects and nurserymen, and results in heavy financial loss to nurserymen in congested sales and their own planting in the short spring season. It greatly lessens the total amount of planting needed for forest, shelter-belt, landscape, fruit, and other economic purposes. A nurseryman may plant all the year. Evergreens can be taken up with a ball of earth even in May and June. The new growth may curve down. After June 20, the spruces, and after July 10, the pines, are firm enough not to wilt. August-September sales with a ball of earth are just as successful as April. The ground is warm and the roots grow rapidly; the ground can be made moist. Weather in September is less dry than in May and June.

Small evergreens up to 2 feet high may be planted in August and September from one part of the nursery to another without balls of earth, if the roots are very carefully dissected out without breaking. There will be more failures if the week following planting is hot and dry.

Planting with balls of earth may continue all winter, especially if the ground is mulched to keep out the frost and permit economical digging of the tree and the hole. The frozen ball of earth is an old method, frequently referred to, but is not an aid. If the ball is frozen solid and remains so for one or two months with dry winds, the top may dry out and die as has occurred with red cedar. If the ball is not frozen, sap can come up to take the place of that lost by transpiration.

A ball of earth 3 feet in diameter is needed for an evergreen 8 to 10 feet high;  $4\frac{1}{2}$  feet in diameter for an evergreen 15 feet high, except red cedar which can have a ball 3 feet; a ball of earth 12 feet in diameter is needed for a pine 35 feet high. Root-pruning pines, spruce and hemlock, permits moving the following year with a smaller ball than otherwise. In root-pruning, the trench

1458. *Picea excelsa*, the Norway spruce. One of the most popular coniferous evergreens.

1459. Picturesque field pine, remnant of a forest

can go three-quarters of the way around or three or four of the larger roots can be left across the trench to keep the tree from blowing over. Root-pruning of red cedars is of less advantage and is rarely practised. In New England and northern New York, the pine, spruce and hemlock, have only a few coarse roots just under the surface and no roots extending 2 feet deep. When moved to better-drained soils on the coastal plain, they develop deeper roots and have ten times as many fibers in a ball 4 feet in diameter. The above evergreens with their shallow root-systems can be taken up with a disc of roots, peat and grass 8 inches deep and 3 to 4 feet wide. This can be set on a wagon and trees 10 to 15 feet high easily moved. Less roots

1460. The beauty of young evergreens lies in their symmetry and the preservation of the lower limbs.

will be broken or bare if the ball is tied in burlap. The usual cause of failure in this operation is neglect of watering. Hemlocks and probably other trees will be aided by shading for the first two months.

RALPH W. CURTIS.

### Broad-leaved evergreens for Washington and the South.

Broad-leaved evergreens hardy at Washington, D.C. The evergreens and half evergreens of foregoing list are also good.

- Abelia floribunda*.  
*Aucuba himalaica*.  
*Aucuba japonica*.  
*Aucuba japonica* var. *concolor*.  
*Buxus balearica*.  
*Buxus sempervirens* var. *arborescens*.  
*Buxus sempervirens* var. *Handsworthii*.  
*Buxus sempervirens* var. *suffruticosa*.  
*Cotoneaster Simonsii* (nearly deciduous at Washington).  
*Cotoneaster thymifolia* (nearly deciduous at Washington).  
*Daphne Laureola*.  
*Elæagnus pungens* var. *reflexa*.  
*Eriobotrya japonica*.  
*Evonymus japonica* var. *macrophylla*.  
*Garrya elliptica*.  
*Ilex aquifolium*.  
*Ligustrum japonicum*.  
*Ligustrum lucidum*.  
*Ligustrum lucidum* var. *aureo-marginatum*.  
*Ligustrum Quihoui* (half evergreen).  
*Ligustrum sinense* (half evergreen).  
*Magnolia grandiflora*. [green].  
*Nandina domestica*.  
*Osmanthus Aquifolium*.  
*Phillyrea angustifolia*.  
*Photinia serrulata*.  
*Prunus Laurocerasus* var. *Bertini*.  
*Prunus Laurocerasus* var. *colchica*.  
*Prunus Laurocerasus* var. *schipkaensis*.  
*Prunus Laurocerasus* var. *rotundifolia*.  
*Pyracantha coccinea*.  
*Rhododendron amœnum*.  
*Rhododendron arbutifolium*.  
*Rhododendron carolinianum*.  
*Rhododendron Hinodegiri*.  
*Rhododendron minus*.

1461. *Picea pungens*. The two small tufts at the right are *P. excelsa* var. *Maxwellii*.

### Broad-leaved evergreens hardy at Norfolk and South

- Berberis congestiflora*.  
*Berberis Darwinii*.  
*Elæagnus pungens* var. *maculata*.  
*Elæagnus pungens* var. *Simonii*.  
*Gardenia jasminoides*.  
*Gardenia jasminoides* var. *Fortunei*.  
*Ilex cornuta*.  
*Laurus nobilis*.  
*Laurus regalis*.  
*Leucothoe acuminata*.  
*Magnolia fuscata*.  
*Magnolia Thompsoniana*.  
*Mahonia Fortunei*.  
*Mahonia nepalensis*.  
*Mahonia trifoliata*.  
*Photinia serrulata*.  
*Prunus caroliniana*.  
*Prunus lusitanica*.  
*Quercus acuta*.  
*Quercus Darlingtonii*.  
*Quercus sempervirens*.  
*Yucca aloifolia*.  
*Yucca Treleaseana*.

The following list of broad-leaved evergreens hardy at Arnold Arboretum may also be expected to thrive at Washington.

- Abelia grandiflora*.  
*Arctostaphylos Uva-ursi*.  
*Azara microphylla*.  
*Buddleia japonica*.  
*Bumelia lanuginosa*.  
*Bumelia lycioides*.  
*Buxus japonica*.  
*Buxus sempervirens*.  
*Cistus laurifolius*.  
*Cotoneaster buxifolia*.  
*Cotoneaster microphylla*.  
*Daphne Blagayana*.  
*Daphne Cneorum*.  
*Daphne pontica*.  
*Ilex crenata*.  
*Ilex glabra*.  
*Ilex opaca*.  
*Ilex vomitoria*.  
*Kalmia angustifolia*.  
*Kalmia latifolia*.  
*Leucothoe axillaris*.  
*Leucothoe Catesbæi*.  
*Mahonia japonica*.  
*Pachistima Canbyi*.  
*Pachistima Myrsinites*.  
*Pernettya angustifolia*.  
*Pernettya mucronata*.  
*Phillyrea decora*.  
*Pieris floribunda*.  
*Pieris japonica*.  
*Prunus Laurocerasus*.  
*Pyracantha coccinea* var. *Lalandii*.  
*Pyracantha coccinea* var. *pauciflora*.  
*Rhododendron amœnum*.  
*Rhododendron indicum*.  
*Yucca filamentosa* and varieties.  
*Yucca floccida* and varieties.  
*Yucca glauca*.  
*Zenobia speciosa* and varieties.

1462. Young trees of *Pinus ponderosa*, useful in the Rocky Mountain region.

A list of broad-leaved evergreens in addition to those recommended for Norfolk, Virginia, for the South Atlantic and Gulf Coast regions and as far inland as Augusta and Montgomery. Those marked "S" thrive only in the warmest sections.

- Arbutus Unedo*.  
*Ardisia crenulata*.  
*Berberis fascicularis*.  
*Bumelia angustifolia*.  
*Bumelia tenax*.  
*Camellia japonica* (S).  
*Cinnamomum Camphora* (S).  
*Cleyera japonica*.  
*Cytisus canariensis*.  
*Cytisus filipes*.  
*Cytisus monspessulanus*.  
*Gardenia florida*.  
*Gardenia Fortunei*.  
*Gardenia radicans*.  
*Helianthemum ocyroides*.  
*Illicium anisatum* (S).  
*Leucothoe acuminata*.  
*Prunus lusitanica*.  
*Prunus versallensis*.  
*Ligustrum nepalense*.  
*Metrosideros floribunda* (S).  
*Myrtus communis*.  
*Nerium odoratum*.  
*Nerium Oleander*.  
*Nerium fragrans*.  
*Olea integrans*.  
*Pittosporum Tobira*.  
*Quercus suber*.  
*Ruscus aculeatus*.  
*Thea Bohea*.  
*Trachycarpus Fortunei* (S).  
*Viburnum odoratissimum*.  
*Viburnum suspensum*.  
*Viburnum Tinus*.  
*Viburnum sandankwa*.

F. L. MILFORD.

### Plants that are evergreen on the middle Great Plains.

It must be remembered that on the Great Plains the conditions vary enormously, and that few plants naturally range over the whole area, or are capable of being successfully grown in artificial plantations throughout the whole area. Two special localities are frequently mentioned in the list. Arbor Lodge is the arboretum established by the late J. Sterling Morton at Nebraska City, within a few miles of the Missouri

River. The University Arboretum is at Lincoln, Nebraska, on the high prairies 60 miles west of the Missouri River.

*Trees.*

*Abies balsamea* (not common).  
*Abies cephalonica* (Arbor Lodge; University Arboretum).  
*Abies cilicica* (Arbor Lodge).  
*Abies concolor* (common).  
*Abies nobilis* (Arbor Lodge).  
*Abies Nordmanniana* (Arbor Lodge).  
*Abies Picea* (Arbor Lodge)=*A. pectinata*.  
*Abies Pinsapo* (Arbor Lodge).  
*Abies Veitchii* (Arbor Lodge; University Arboretum).  
*Chamaecyparis pisifera* (Arbor Lodge).  
*Juniperus scopulorum* (native in western portion).  
*Juniperus virginiana* (native in eastern portion).  
*Juniperus virginiana* var. *aurea variegata* (University Arboretum).  
*Juniperus virginiana* var. *elegantissima* (University Arboretum).  
*Juniperus virginiana* var. *glauca* (University Arboretum).  
*Picea Alcockiana* (Arbor Lodge; University Arboretum).  
*Picea canadensis* (common)=*P. alba*.  
*Picea Engelmanni* (rare).  
*Picea excelsa* (common)=*P. Abies*.  
*Picea excelsa* var. *inverta* (University Arboretum).  
*Picea excelsa* var. *pumila* (University Arboretum).  
*Picea excelsa* var. *pumila compacta* (University Arboretum).  
*Picea mariana* (Arbor Lodge)=*P. nigra*.  
*Picea orientalis* (Arbor Lodge).  
*Picea nigra* (University Arboretum)=*P. mariana*.  
*Picea nigra* var. *Doumetti* (University Arboretum).  
*Picea Parryana* (common)=*P. pungens*.  
*Picea polita* (Arbor Lodge; University Arboretum)=*P. Torano*.  
*Pinus austriaca* (very common; University Arboretum).  
*Pinus austriaca* var. *cebnensis* (monspeliensis) (University Arboretum).  
*Pinus cembra* (Arbor Lodge).  
*Pinus divaricata* (common)=*P. Banksiana*.  
*Pinus laricio* (Arbor Lodge).  
*Pinus massoniana* (Arbor Lodge).  
*Pinus montana* (Arbor Lodge; University Arboretum).  
*Pinus resinosa* (not common).  
*Pinus rigida* (Arbor Lodge).  
*Pinus scopulorum* (native in western portion).  
*Pinus Strobus* (common).  
*Pinus sylvestris* (very common).  
*Pseudotsuga taxifolia* (common)=*P. Douglasii*.  
*Taxodium distichum* (not common).  
*Taxus canadensis* (Arbor Lodge).  
*Thuja occidentalis* (common).  
*Thuja orientalis* (Arbor Lodge; University Arboretum).  
*Tsuga canadensis* (Arbor Lodge).

*Shrubs.*

*Arctostaphylos Uva-ursi* (native in western portion).  
*Berberis ilicifolia* (University Arboretum).  
*Buxus* (not common; tender at University Arboretum).  
*Evonymus japonica* (University Arboretum).  
*Evonymus nana?* (University Arboretum).  
*Evonymus radicans* (University Arboretum).  
*Hedera helix* (rarely hardy; tender).  
*Ilex opaca* (rarely planted; tender).  
*Juniperus chinensis* (University Arboretum).  
*Juniperus communis* var. *aurea* (University Arboretum; tender).  
*Juniperus communis* (native in western portion; University Arboretum).  
*Juniperus communis* var. *hibernica* (University Arboretum; tender).  
*Juniperus sabina* var. *prostrata* (University Arboretum).  
*Juniperus stricta* (University Arboretum).  
*Ligustrum Iota* (half evergreen; University Arboretum).  
*Ligustrum ovalifolium* (evergreen; half hardy; University Arboretum).  
*Ligustrum ovalifolium* var. *aurea* (half evergreen; hardy; University Arboretum).  
*Ligustrum vulgare* (half evergreen; University Arboretum).  
*Ligustrum vulgare* var. *buxifolium* (evergreen, hardy; University Arboretum).  
*Ligustrum vulgare* var. *fructealba* (half evergreen; University Arboretum).  
*Lonicera japonica* var. *Halliana*.  
*Mahonia Aquifolium* (native in western portion).  
*Rhododendron maximum* (rarely planted; tender).  
*Smilax hispida* (half evergreen; native).  
*Yucca filamentosa* (common).  
*Yucca glauca* (native in western portion).

*Herbs.*

*Equisetum hiemale* (native throughout).  
*Equisetum laevigatum* (native throughout).  
*Equisetum scirpoides* (native throughout).  
*Equisetum variegatum* (native throughout).  
*Iris germanica*.  
*Iris pumila*.  
*Mamillaria missouriensis* (native in western portion).  
*Mamillaria viviparus* (native in western portion).  
*Opuntia arborescens* (native in southwestern portion).  
*Opuntia camanchiana* (native in southwestern portion).  
*Opuntia fragilis* (native throughout).

*Opuntia humifusa* (native throughout).  
*Opuntia polyacantha* (native throughout).  
*Opuntia tortispina* (native in southern portion).  
*Pellaea atropurpurea* (native throughout).  
*Salvia officinalis* (common).  
*Selaginella rupestris* (native throughout).  
*Vinca minor* (common).

*Rosettes.*

Many herbaceous plants have rosettes of green leaves throughout the winter, the following being the more conspicuous on the Great Plains.

*Capsella Bursa-pastoris* (throughout the region; common cruciferous weed, introduced long ago and known as "shepherd's purse").  
*Dianthus* } (several species).  
*Plantago* }  
*Rumex* }  
*Fragaria virginiana* (throughout the region).  
*Geum canadense* (throughout the region).  
*Hieracium longipilum* (in eastern portion).  
*Oenothera biennis* (throughout the region).  
*Pentstemon grandiflorus* (throughout the region).  
*Pyrola chlorantha* (in the western portion).  
*Pyrola elliptica* (in the western portion).  
*Pyrola secunda* (in the western portion).  
*Taraxacum officinale* (throughout the region); not green in University Arboretum, Lincoln, except where covered by snow.  
*Taraxacum erythrospermum*.  
 CHARLES E. BESSEY.

**EVERLASTINGS.** A term applied to flowers or plants that retain their shape and other characteristics after being dried; equivalent to the French word "immortelle." With everlastings are also included various artificial or manufactured articles that imitate flowers or plants.

The most important commercially of the flowers that retain their form and color in a dried state have been the French immortelles, *Helichrysum arenarium*. These flowers are used very extensively in France in their natural yellow color, for the manufacture of memorial wreaths and crosses, which, being constructed very compactly, are exceedingly durable, even in the severest weather, and are exported in large numbers to all parts of the world. The flowers bleached white, or bleached and then dyed in various colors, are also shipped in enormous quantities, either direct to this country or by some of the large exporting houses of Germany. In the United States, however, the use of these immortelles has fallen off on account of the high duty.

Approaching the French immortelles in aggregate value have been the so-called "cape flowers," *Helichrysum grandiflorum*, which formerly reached an enormous sale in this country, and they largely supplanted the immortelles on account of their silvery texture and greater beauty every way. They are naturally white, but require bleaching in the sun to give them the desired luster. They came from the Cape of Good Hope, and reached this country mainly from Hamburg. Of recent years, these products have been less important in the American trade because of the uncertainty of the crop, poor quality, and the competition of artificial materials. There is now being made in Germany an artificial "cape flower;" this flower is made from paper and waxed, and is an excellent imitation African cape. Large quantities of these goods are being imported into this country, and they have given great satisfaction to all florists that have used them. Probably in time the German product will

1463. A mature field tree of *Pinus ponderosa*.

entirely supersede the natural African cape, more particularly as each flower has a wire stem which the florists attach to the toothpicks or sticks, and this saves considerable labor.

The common everlasting of American and English country gardens, *Helichrysum bracteatum*, is the only one of these flowers grown to any extent in North America, and more or less extensive cultivation of it, commercially, has been practised in this country but a large percentage is still imported. These plants come in white, straw and brown colors naturally, and take readily to a variety of artificial tints; together with *Ammobium alatum* and the well-known globe amaranth, *Gomphrena globosa*, they are grown and used to a considerable extent by the country folk in the construction of the many forms of wreaths, stars, and other Christmas forms, which they sell in the city markets in large quantities, but their sale by wholesalers and jobbers for general consumption is very limited. *Statice incana*, cultivated or wild from the swamps of southern Europe, and *Gypsophila* in several species are used to a considerable extent; and the sale of statice especially, which is popular in combination with cape flowers in memorial designs, is quite an item with the dealers in florists' supplies.

Of the dried grasses, the pampas plumes of California, *Cortaderia argentea*, native of South America, are the only American production attaining any great commercial importance. Their beautiful silky plumes, unapproached by any other horticultural product, are used in enormous quantities for decorative purposes, and are an important item of American export. They are used mainly in a sun-bleached state, but more or less dyeing, often parti-colored, is also done. *Bromus brizæformis* is the most extensively used of the smaller grasses. It is mostly imported from Europe. It can be imported, however, including duty, for about 25 per cent less than it is possible to grow it in this country. It is handled in the natural state. *Briza maxima*, another popular grass, is grown in Italy. *Briza media*, a medium-sized grass, and *Briza minima*, the flowers of which are as fine as sawdust, are also handled in the same way as *Briza maxima*, very little of the *B. minima* being used dyed, however. *Phleum pratense*, *Stipa pennata*, and various kinds of oats have more or less commercial value, being used considerably in the manufacture of imitation flowers and straw goods, but from a florist's standpoint they are not important. The most important commercially of the imported grasses is the Italian wheat, the quantities used in this country for the manufacture of sheaves for funeral purposes being enormous, and increasing yearly. It comes in many grades of fineness and length of stem. In this country all attempts to cultivate it in competition with the European product have failed. Of late years, a decorative natural grass called "Minerva" and treated artificially is being imported in large quantities, and is used by florists in combinations, making a very effective setting-off to flowers in basket decoration.

Much use is now made in this country of the dried twigs and foliage of ruscus. This is grown in Italy, and is shipped to Germany where it is prepared and dyed in many attractive colors. It holds its form well. It is made up into wreaths and other articles, and provides a good foliage effect.

Enormous use is now made of magnolia leaves prepared and colored in brown, red and green. In former years these goods were secured from Germany and Italy, but they are no longer imported for the reason that they are prepared in this country as good, if not better than they are on the other side, and much cheaper. They are gathered and prepared in Florida, and shipped to all parts of the United States, put in cartons containing about 1,000 leaves. They are used very extensively by all classes of florists on account of their lasting qualities and fine appearance. They have

almost entirely superseded the galax leaf, which has been in use for so many years in the making up of mortuary emblems.

A number of our native composites—of the genera *Gnaphalium*, *Antennaria* and *Anaphalis*—are called everlastings, and are often used in home decorations, particularly in the country; but they have no commercial rating.

There is an increasing demand for artificial decorative articles, to be used alone and in conjunction with fresh cut-flowers; they are now being used by the best florists and plantmen. The demand for decorative artificial flowers, plants and like materials, has grown to such an extent that there are now a large number of businesses devoted exclusively to the manufacture of them. This is well illustrated in the product called "Japanese wood frieze," in appearance resembling very much the well-known worsted and silk chenille. It is made from wood-fiber colored in shades to represent the colors of immortelles. This frieze or wood chenille, when worked up in various designs, so closely resembles immortelles that the difference between them can hardly be detected.

One of the interesting artificial greens is the "sea moss." It is an alga-like hydroid (one of the animal kingdom), known as *Sertularia argentea*, which is commonly distributed along our Atlantic coast northward from New Jersey to the Arctic. The long moss-like strands are dyed bright green, and the "plant" is used in making table decorations and jardinière pieces. It is sometimes called "air plant." The apparent lateral minute buds clothing all the branches are, of course, the shelter for the zooids of the colony during life. There is another one (*Aglaophenia struthionides*) found on the Pacific coast, which is even more beautiful, and which is put to the same decorative uses, and is known there as the ostrich plume, the branches having a beautiful pinnate arrangement along the two sides of a single axis. These sea-mosses are dried, the dirt picked out, and then dyed and fixed in a preparation to make them permanent. They are likely to have an unpleasant odor.

H. BAYERSDORFER.  
WM. N. REED.†

#### Everlastings for home use.

After much experience with the growing of everlastings for home winter decorations, the three following species have been found the best for plantings: *Helichrysum monstrosum*, the double form of *H. bracteatum*, known as "golden ball," *Acroclinium (Helipterum) roseum flore-pleno*, and the Chinese lantern plant, *Physalis Franchetii*. These are easily grown, are free bloomers and give better and brighter color in their dried state than other forms. They have a certain warmth in color that is appreciated in zero weather.

The helichrysum and acroclinium are started in the greenhouse or hotbed during the latter part of March, planting them out in full sun as soon as all danger of frost is past. Any good garden soil suits them.

It is most important that the flowers of the acroclinium be picked just as soon as the buds show color, even if they look almost too small, because if too far advanced the ray petals open up flat, exposing the center, which will soon turn brown when dried and spoil the effect. Those cut early will open up part way, presenting only their full color. In full blooming season they should be picked daily. With the helichrysum one can wait until the bud is of fairly good size but all the smaller ones will open up also when dried. Those fully open or showing the center at all will turn brown. With both plants pluck off all foliage, place in bundles and hang them, heads down, in some dry closet. They should be examined at times, as in the drying the stems shrink and the flower may fall down. They should remain in this dry shelter until the house is heated in the

fall, reducing the moisture in the air, otherwise the dry flower-stems would absorb the moisture and become limp.

A certain number of "droopers" is wanted when arranging a bouquet, in order to avoid stiffness. These are easily secured. Take a long sheet of a pliable cardboard about 8 inches wide, tack one edge lengthwise on the top of a shelf, at the front bringing it out and downward so as to form a half circle, and fasten it there. Then lay the freshly picked flower-stems on the shelf, heads hanging down. It is sometimes necessary to place a book or some weight on the stems to keep them in place. They will dry in this curved form. Brown split bamboo baskets make good vases, as they harmonize well with the deep orange of the golden ball and the pink of the acroclinium. A wire mesh in these baskets enables the flowers to be arranged more easily. As there is no green foliage used, it is well to use some short-stemmed flower in the center, midway between the basket and the tallest flowers. These "flecks" of color relieve the bareness of the stems.

The Chinese lantern plant (*Physalis Franchetii*) is an easily grown perennial, spreading at the roots. The seed-pods are very ornamental, retaining their brilliancy of color when dried, the colors ranging from a pale green to orange and red. They hang like inverted balloons, on slender peduncles and lose their graceful appearance unless the main stem that carries them can be curved outward when dry. They have to be treated differently from the others. Boards on a partition in a wood-shed may be used, driving tacks, one each side, close up to the side of the bottom of the main stem, the heads of the tacks overlapping the stick. Run the stem up straight for about 6 inches, then curve to right or left and fasten in same manner. Then, when dried, the lanterns will hang clear of the stem. The seed-pods of the balloon vine, *Cardiospermum Halicacabum*, work in well among the lanterns. Cut away part of the side of the lantern, and see the brilliant wick inside.

W. C. EGAN.

**EVODIA** (Greek, *pleasant odor*). *Rutaceæ*. Ornamental woody plants grown chiefly for their handsome foliage.

Deciduous or evergreen trees or shrubs: trunk with smooth bark: winter-buds naked: lvs. opposite, petioled, simple or pinnate with entire punctate lfts.: fls. in terminal or axillary panicles or corymbs, unisexual, usually 4-merous, less often 5-merous; sepals imbricate; petals valvate or slightly imbricate; stamens 4-5, at the base of a cupular disk: carpels 4-5, each with 2 ovules, nearly free or connate, with a cylindric style, at maturity dehiscent, 2-valved, 1-2-seeded.—About 50 species in E. Asia, from Korea and N. China to S. Asia., Austral. and Polynesia. Allied to *Zanthoxylum* which is easily distinguished by its alternate lvs.; very similar in habit and foliage to *Phellodendron* which besides in the berry-like frs. differs in the winter buds being inclosed in the base of the petiole, while in *Evodia* they are borne free in the axils.

The cultivated hardy species are strong-growing deciduous trees with rather large pinnate leaves of aromatic odor when bruised, and with whitish flowers in terminal broad panicles followed by small capsules exposing glossy black seeds when opening. *Evodia Daniellii* has proved hardy at the Arnold Arboretum. *E. glauca* and *E. Henryi*, are somewhat tenderer. There are also a few tropical species from New Guinea, rarely cultivated as warmhouse evergreens; they are little known and their correct names have not yet been determined. Propagation is by seeds and of the warmhouse species by cuttings of half-ripened wood; probably also by root-cuttings.

A. Frs. *obtuse or only mucronulate at the apex*.

*glauca*, Miq. (*E. Fargesii*, Dode). Tree, to 50 ft.: lfts. 5-11, usually 7, on slender slightly hairy stalks,

$\frac{1}{4}$ - $\frac{1}{2}$  in. long, elliptic-ovate to oblong-lanceolate, long-acuminate, broadly cuneate or rounded at the base, minutely crenulate, glaucous below and glabrous except hairs along the midrib near the base,  $2\frac{1}{2}$ -4 in. long: infl. corymbose, 6-8 in. broad, nearly glabrous; pistil of the staminate fls. glabrous: fr. about  $\frac{1}{4}$  in. long, finely pubescent. June; fr. Sept. Cent. China.

AA. Frs. *strongly beaked*.

**Hénryi**, Dode. Tree, to 35 ft.: lfts. 5-9, short-stalked, ovate-oblong to ovate-lanceolate, long-acuminate, rounded or narrowed at the base, finely crenulate, glaucescent or pale green below and glabrous,  $2\frac{1}{2}$ -4 in. long: infl. paniculate, 2- $2\frac{1}{2}$  in. across: fr. reddish brown, sparingly hairy,  $\frac{1}{4}$  in. long, with slender beaks about half as long. June; fr. Sept. Cent. China. See page 3568.

**Daniellii**, Hemsl. (*Zanthoxylum Daniellii*, Bennett). Small tree: lfts. 7-11, ovate to oblong-ovate, acuminate with an obtusish point, rounded at the base, sometimes subcordate or broadly cuneate, pale green below and glabrous except hairs along the midrib and sometimes on the veins, 2- $3\frac{1}{2}$  in. long: infl. corymbose, 4-6 in. across: fr. nearly  $\frac{1}{2}$  in. long, slightly hairy or nearly glabrous, with a rather short, usually hooked beak. June; fr. Sept. N. China, Korea.

*E. elegans*, Hort. Evergreen: lvs. 3-foliolate; lfts. linear-lanceolate, undulate and crenate; resembling *Aralia elegantissima*. New Guinea. F.E. 1899:291. Gng. 12:404. G. 21:273.—*E. formosa*, Hort. A similar species, intro. in 1900 by Sander & Co. This and the preceding are warmhouse evergreens and belong probably to species already described.—*E. officinalis*, Dode. Allied to *E. glauca*. Small tree: lfts. 5-11, ovate to elliptic-oblong, acuminate, pubescent and light green beneath: infl. pubescent: fr. glabrous, Cent. China.—*E. rutecarpa*, Hook. f. & Thoms. Allied to *E. glauca*. Small deciduous tree: lft. short-petioled, broader, pubescent on both sides: infl. smaller and denser, with stout pedicels, pubescent, Japan. Himalayas. S.Z. 1:21 (as *Boymia rutecarpa*).—*E. reticulata*, Rehd. & Wilson. Allied to *E. Henryi*, but lvs. and young branchlets densely short-pubescent: fruiting corymb 4-8 in. across. Cent. China.

ALFRED REHDER.

**EVÓLVULUS** (*to unroll*, because not twining as in *Convolvulus*). *Convolvulacæ*. Prostrate or erect annual or perennial herbs or sub-shrubs, rarely planted or grown in greenhouses. The genus differs from *Convolvulus* in having 2 styles 2-cleft, stigmas always narrow, corolla often open or rotate, and not twining: lvs. entire, small: fls. small, in summer and autumn; sepals 5, the calyx not bracted at base; corolla blue, rose or white, 5-angled or shortly 5-lobed. The species are about 80; in warm regions, several in the U. S. *E. purpureo-cæruleus*, Hook., of Jamaica, appears to be the only species prominently mentioned horticulturally, and this is seldom planted: 1-2 ft., woody at base: lvs. small, lanceolate-acute: fls. purplish, terminal, the corolla rotate, white-centered and purple-rayed. B.M. 4202.

**EVÓNYMUS** (ancient Greek name). Often spelled *Euonymus*. *Celastracæ*. SPINDLE-TREE. Woody plants, erect or climbing, grown chiefly for their handsome foliage and the attractive fruits.

Deciduous or evergreen shrubs or small trees with usually more or less 4-angled branches, mostly erect, rarely creeping or climbing by rootlets: winter-buds usually conspicuous with imbricate scales: lvs. opposite, petioled, usually serrate, and mostly glabrous: fls. small, in axillary cymes, 4-5-merous, generally perfect; style and stamens short, the latter inserted on a disk: fr. a 3-5-lobed, somewhat fleshy caps., each dehiscent valve containing 1 or 2 seeds inclosed in a generally orange-colored aril; the seed itself is white, red or black.—About 120 species in the northern hemisphere, most of them in Cent. and E. Asia, extending to S. Asia and Austral.

The spindle-trees are of upright or sometimes procumbent or creeping habit, with rather inconspicuous greenish, whitish or purplish flowers in axillary cymes; very attractive in fall, with their handsome scarlet,

pink or whitish, capsular fruits, showing the bright orange seeds when opening, and with the splendid fall coloring that most of the species assume, especially *E. alata*, *E. Maackii*, *E. sanguinea*, *E. verrucosa*, *E. europæa* and *E. atropurpurea*. The wood is tough, close-grained and light-colored, often almost white, and used, especially in Europe, for the manufacture of small articles. The bark of *E. atropurpurea* has medical

1464. *Evonymus obovata*. ( $\times \frac{3}{4}$ )

properties.—Most of the cultivated deciduous species, except those from Himalayas, are hardy North, while of the evergreen ones only *E. radicans* is fairly hardy, and, on account of its greater hardiness, is often used North as a substitute of the ivy for covering walls, rocks and trunks of trees, climbing if planted in good soil, to a height of 15 and sometimes 20 feet. *E. europæa*, and South, the evergreen *E. japonica* are sometimes used for hedges.

The spindle-trees are not particular as to the soil and are well adapted for shrubberies. Propagation is by seeds which are usually stratified and sown in spring, or by cuttings of ripened wood in fall. The evergreen species grow readily from cuttings of half-ripened wood under glass in fall or during the winter in the greenhouse. Varieties are sometimes grafted or budded on stock of their typical species.

#### INDEX.

#### A. *Foliage deciduous*. Nos. 1-13.

##### B. *Caps. tuberculate, depressed-globose: fls. 5-merous*.

1. *americana*, Linn. STRAWBERRY BUSH. Upright shrub, to 8 ft.: lvs. ovate-lanceolate or oblong-lanceolate, usually acute at the base, acuminate, crenately serrate,  $1\frac{1}{2}$ -3 in. long; peduncle slender, few-fl.; fls. yellowish or reddish green: fr. pink. June; fr. Sept.-Oct. From S. N. Y. south, west to Texas. L.B.C. 14: 1322. B.B. (ed. 2) 2:491. Var. *angustifolia*, Wood (*E. angustifolia*, Pursh). Lvs. lanceolate or linear-lanceolate, half-evergreen S.

2. *obovata*, Nutt. (*E. americana* var. *obovata*, Torr. & Gray). Fig. 1464. Procumbent shrub, with rooting st. and erect branches, to 1 ft.: lvs. obovate or elliptic-obovate, crenately serrate, light green, 1-2 in. long; fls. purplish: caps. usually 3-celled. May; fr. Aug., Sept. From Canada to Ind. and Ky. G.F. 9:385 (adapted in Fig. 1464).—It may be used for covering the ground under large trees, or for borders of shrubberies. Var. *variegata*, Hort., has the lvs. marked pale yellow.

##### BB. *Caps. smooth: fls. generally 4-merous*.

##### C. *Fr. divided to the base into 4 or less nearly separate pods*.

3. *alata*, Maxim. (*E. Thunbergiana*, Blume. *E. striata*, Loes.). Spreading shrub, to 8 ft.: branches stiff, with 2-4 broad, corky wings: lvs. elliptic or obovate, acute at both ends, sharply serrate, 1-2 in. long; fls. 1-3, short-peduncled, yellowish: caps. purplish, small; seeds brown with orange aril. May, June; fr. Sept., Oct. China, Japan. S.I.F. 1:63. F.E. 32:54. Var. *subtriflora*, Franch. & Sav. Branches not winged: fls. 1-5. Var. *aperta*, Loes. Aril open at the apex, disclosing the black seed. Cent. China.—This species is one of the handsomest; the lvs. turn bright crimson in autumn, the small, but numerous frs. are brightly colored and in winter the shrub is conspicuous by its broadly winged branches.

##### CC. *Fr. more or less 3-5-lobed*.

##### D. *Branches densely warty*.

4. *verrucosa*, Scop. Erect shrub, to 6 ft.: lvs. ovate-lanceolate, crenately serrulate, acuminate, 1-2½ in. long; fls. slender-peduncled, 1-3, brownish: caps.

1465. *Evonymus europæa*. ( $\times \frac{1}{2}$ )

deeply 4-lobed, yellowish red; seed black, not wholly covered by the orange aril. May, June; fr. Aug. S. E. Eu., W. Asia. H.W. 3, p. 55.

##### DD. *Branches smooth*.

##### E. *Antlers yellow*.

##### F. *The caps. with obtuse lobes*.

5. *nana*, Bieb. Low shrub, to 2 ft., with slender, often arching or sometimes procumbent and rooting

branches: lvs. linear or linear-oblong, mucronulate, entire or remotely denticulate and revolute at the margins,  $\frac{1}{2}$ – $1\frac{1}{2}$  in. long: fls. slender-peduncled, purplish: caps. deeply 4-lobed, pink; seed brown, not wholly covered by the orange aril. May, June; fr. Aug. W. Asia to W. China.—Handsome shrub for rockeries and rocky slopes; forming a graceful, pendulous, standard tree if grafted high on *E. europæa*. Fr. ripens in Aug., earliest of all species. Var. *Koëpmannii*, Beissn. (*E. Koëpmannii*, Lauche). Lvs. larger and broader.

6. *europæa*, Linn. (*E. vulgaris*, Mill.). Fig. 1465. Erect shrub or sometimes small tree, to 20 ft.: lvs. ovate or oblong-lanceolate, acuminate, crenately serrate,  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. long: fls. yellowish, in few-fl. cymes: caps. 4-lobed, usually pink. May. Eu. to E. Asia. B.B. (ed. 2) 2:492. H.W. 3, p. 53.—Varying with narrower and broader lvs. There are also several varieties with variegated lvs. and some with frs. of different colors, as var. *atrórubens*, Rehd. (*E. vulgaris* var. *atrórubens*, Schneid. *E. europæa* fr. *atropurpurea*, Hort.), with deep purple frs.; var. *leucocárpa*, DC. (*E. europæa* fr. *álbo*, Hort.), with whitish frs., and var. *atropurpurea*, Arb. Kew, with rather narrow purplish lvs. Var. *nana*, Lodd., is a dwarf, dense, and strictly upright form with elliptic to elliptic-lanceolate lvs.  $1\frac{1}{2}$  in., or on vigorous shoots, to  $2\frac{1}{2}$  in. long: it hardly ever flowers and is tenderer than the type.

FF. The caps. with winged lobes: lvs. broad.

7. *latifolia*, Scop. Shrub or small tree, to 20 ft.: winter-buds elongated, acute, about  $\frac{1}{2}$  in. long: lvs. obovate-oblong, acuminate, crenately serrate, 2–4 in. long: fls. yellowish, often 5-merous, in slender-peduncled, rather many-fl. cymes: caps. pink, large, with winged lobes. May, June; fr. Sept. S. Eu., W. Asia. B.M. 2384. Gn. 39, p. 213. Gt. 53, p. 30. G. 4:235. H.W. 3, p. 54. F.S.R. 3, p. 29.—A very decorative species, with handsome foliage and large pendulous frs.

8. *sanguinea*, Loes. Shrub or small tree, to 20 ft.: winter-buds elongated, acute: branchlets nearly terete: frs. broadly oval or ovate to elliptic-ovate, acute, broadly serrate or rounded at the base, densely fimbriate-serrulate, dull green above, paler below and slightly reticulate,  $1\frac{3}{4}$ –4 in. long: cymes lax, long-peduncled; fls. usually 4-merous. fr. purple, slightly lobed, 4-winged, the wings  $\frac{1}{4}$ – $\frac{1}{2}$  in. long; aril orange, entirely covering the black seed. June; fr. Sept. Cent. and W. China. Var. *brevipedunculata*, Loes. Peduncles about 1 in. long. W. China. Var. *camptoneura*, Loes. Lvs. oval or ovate to elliptic-ovate, veins curved (broader in the type and veins nearly straight). Cent. and W. China.

1466. *Evonymus radicans*.

EE. Anthers purple.

F. Fls. purple.

9. *atropurpurea*, Jacq. (*E. americana*, Hort.). BURNING BUSH. Shrub or small tree, to 20 ft.: lvs. elliptic, acuminate, obtusely serrate, pubescent beneath,  $1\frac{1}{2}$ –5 in. long: fls. purple, in slender-peduncled, many-fl. cymes: caps. deeply 3–4-lobed, scarlet. June; fr. Oct. E. N. Amer., west to Mont. B.B. (ed. 2) 2:491.

FF. Fls. yellowish or whitish.

G. Petioles one-fifth to one-sixth as long as the lf.; lvs. acute or gradually acuminate: fr. pink.

H. Lvs. oblong to ovate-oblong, broadest about or below the middle.

10. *Maackii*, Rupr. (*E. Hamiltoniana*, Dipp., not Wall.). Large shrub or small tree, glabrous: lvs. elliptic-oblong to oblong-lanceolate, acuminate, gradually narrowed toward the base, serrulate, 2–3 in. long and  $\frac{3}{4}$ – $1\frac{1}{4}$  in. broad: cymes small, about  $\frac{3}{4}$  in. across: fr. pink, 4-lobed, about  $\frac{1}{2}$  in. across; aril orange-red, usually closed, rarely slightly opened at the apex. June: fr. Sept. N. E. Asia.

11. *hians*, Koehne. Large shrub: lvs. ovate-oblong, short-acuminate, rounded or broadly cuneate at the base, serrulate,  $2\frac{1}{2}$ – $4\frac{1}{2}$  in. long and  $1\frac{1}{4}$ – $1\frac{3}{4}$  in. broad: cymes rather long-stalked, small; stamens with very short filaments: fr. pink, turbinate, deeply 4-lobed,  $\frac{1}{2}$  in. across; aril blood-red, open at the apex and disclosing the blood-red seed. June; fr. Sept. Japan. S.I.F. 2:39 (as *E. europæa*).

HH. Lvs. generally obovate or obovate-oblong, to  $2\frac{1}{2}$  in. broad.

12. *yedoensis*, Koehne (*E. Sieboldiana*, Rehd., not Blume). Large shrub: lvs. usually obovate, sometimes elliptic, broadly cuneate at the base, abruptly acuminate, serrulate, 2–5 in. long and  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. broad: cymes long-stalked, rather dense and many-fl.: fr. pink, deeply 4-lobed,  $\frac{1}{2}$  in. across; aril orange, usually closed. June; fr. Sept. Japan. Gt. 53, p. 31. S.T.S. 1:62. F.E. 31:125. Var. *calocarpa*, Koehne. Fr. bright carmine. Var. *Koehneana*, Loes. Lvs. hairy on the veins below. Cent. China.

GG. Petioles usually a third to a fourth as long as the lf., lvs. abruptly long-acuminate: fr. pale yellowish or pinkish white.

13. *Bungeana*, Maxim. Shrub, to 15 ft., with slender branches: lvs. slender-petioled, ovate-elliptic or elliptic-lanceolate, long-acuminate, finely serrate, 2–4 in. long: fls. in rather few-fl. but numerous cymes: fr. deeply 4-lobed and 4-angled; seeds white or pinkish, with orange aril. June: fr. Sept., Oct. China, Man-

churia, M.D.G. 1899:569.—Very attractive with its rather large, profusely produced frs., remaining a long time on the branches. Var. *semipersistens*, Schneid. (*E. Hamiltoniana* var. *semipersistens*, Rehd. *E. Sieboldiana*, Hort., not Blume). Lvs. elliptic, long-acuminate, half-evergreen, keeping its bright green foliage S. until mid-winter: fr. bright pink, usually sparingly produced and ripening very late.

AA. *Foliage evergreen or half-evergreen (see also the preceding var.).*

B. *Lvs. rather thin, half-evergreen.*

14. *pätens*, Rehd. (*E. kiautschowica* var. *pätens*, Loes. *E. Sieboldiana*, Hort., not Blume). Spreading shrub, to 10 ft., the lower branches sometimes procumbent and rooting; branchlets obscurely 4-angled, minutely warty: lvs. elliptic to elliptic-oblong, rarely obovate-oblong, acute, cuneate at the base, crenately serrulate, bright green above: cymes 2-3 in. across, loose, slender-peduncled: fr. subglobose, pink; seed pinkish brown, covered entirely by the orange aril. Aug., Sept.; fr. Oct., Nov. Cent. China. S.T.S. 1:64.—Hardy as far north as N. Y., in sheltered positions to Mass. One of the best shrubs for winter-effect on account of its abundant late-ripening frs. and the handsome foliage remaining on the branches until spring except when destroyed by severe frost.

BB. *Lvs. thickish, evergreen.*

15. *japónica*, Linn. Upright shrub, to 8 ft., with smooth and slightly quadrangular or striped branches: lvs. obovate to narrow-elliptic, cuneate at

1467. *Evonymus radicans*.

the base, acute or obtuse, obtusely serrate, shining above,  $1\frac{1}{2}$ - $2\frac{1}{2}$  in. long: fls. greenish white, 4-merous, in slender-peduncled, 5- to many-fl. cymes: caps. depressed, globose, smooth, pink. June, July; fr. Oct. S. Japan. S.I.F. 2:39. B.R. 30:6.—A very variable species. Var. *macrophylla*, Sieb. (var. *robusta*, Hort.). Lvs. oval, large,  $2\frac{1}{2}$ -3 in. long. Var. *microphylla*, Sieb. (*E. pulchella*, Hort. *Eurya microphylla*, Hort.). Lvs. small, narrow-oblong or oblong-lanceolate. Var. *columnaris*, Carr. (var. *pyramidalis*, Hort.). Of upright, columnar habit: lvs. broadly oval. There are many varieties with variegated lvs.; some of the best are the following: Var. *argenteo-variegata*, Regel. Lvs. edged and marked white. Var. *aureo-variegata*, Regel. Lvs. blotched yellow. Lowe, 49. Var. *albo-marginata*, Hort. Lvs. with white, rather narrow margins. Var. *medio-picta*, Hort. Lvs. with a yellow blotch in the middle. Var. *pallens*, Carr. (var. *flavescens*, Hort.). Lvs. pale yellow when young; similar is var. *aurea*, Hort., but the yellow is brighter and changes more quickly to green. Var. *viridi-variegata*, Hort. (var. *Duc d'Anjou*, Hort.). Lvs. large, bright green, variegated with yellow and green in the middle. Var. *aureo-marginata*, Hort. Lvs. edged yellow. F.E. 16:436; 29:815.

16. *radicans*, Sieb. (*E. japonica* var. *radicans*, Regel. *E. repens*, Hort.). Figs. 1466, 1467. Low, procumbent shrub, with often trailing and rooting or climbing branches, climbing sometimes to 20 ft. high: branches terete, densely and minutely warty: lvs. roundish to elliptic-oval, rounded or narrowed at the base, crenately serrate, usually dull green above, with whitish

veins,  $\frac{1}{2}$ -2 in. long: fls. and fr. similar to the former, but fr. generally of paler color. June, July; fr. Oct. N. and Cent. Japan. R.H. 1885, p. 295. G.C. II. 20:793. M.D. 1906, p. 219.—Closely allied to the former, and considered by most botanists as a variety; also very variable. Var. *Carrièrei*, Nichols. (*E. Carrièrei*, Vauv.). Low shrub, with ascending and spreading branches: lvs. oblong-elliptic, about  $1\frac{1}{2}$  in. long, somewhat shining. G.W. 8, p. 16. Var. *argenteo-marginata*, Rehd. Lvs. bordered white. Var. *roseo-marginata*, Rehd. Lvs. bordered pinkish. Var. *reticulata*, Rehd. (var. *picta*, Hort., var. *argenteo-variegata*, Hort. *E. gracilis*, Sieb.). Lvs. marked white along the veins. R.H. 1876, p. 354; 1878, p. 135. G.W. 1, p. 475. A.G. 19:37. Var. *minima*, Simon-Louis (*E. kewensis*, Hort.). Lvs. marked like those of the preceding variety but smaller,  $\frac{1}{4}$ - $\frac{1}{2}$  in. long.

Var. *végeta*, Rehd. Low spreading shrub, to 5 ft., usually with a few prostrate rooting branches at the base, and climbing high, if planted against a wall: lvs. broadly oval or almost suborbicular, acutish or obtusish, crenately serrulate,  $1\frac{1}{4}$  in. long, those of the rooting branchlets smaller and thinner and generally ovate. Japan. S.T.S. 1:65. M.D.G. 1908:13.—Handsome and hardy shrub; the frs. appear in great profusion and remain on the branches a long time. Var. *acuta*, Rehd. (*E. japonica* var. *acuta*, Rehd.). Rooting and climbing: lvs. elliptic or ovate-elliptic, acute or short-acuminate, serrulate, with the veins below slightly elevated. Cent. China.

*E. Aquifolium*, Loes. & Rehd. Evergreen shrub, to 10 ft.: lvs. coriaceous, nearly sessile, ovate to ovate-oblong, spiny sinuate-dentate: fr. 4-lobed, usually solitary. W. China. One of the most striking species on account of its holly-like lvs.—*E. echinata*, Wall. Usually creeping or climbing, with rooting branches: lvs. ovate-lanceolate: fr. spiny. Himalayas. B.M. 2767.—*E. fimbriata*, Hort., not Wall.—*E. pendula*.—*E. grandiflora*, Wall. Shrub, to 12 ft.: lvs. obovate or obovate-oblong, finely and acutely serrate: fls. white  $\frac{1}{2}$  in. across: fr. globose, yellow; aril scarlet. Himalayas, W. China.—*E. Hamiltoniana*, Wall. Allied to *E. Maackii*. Small tree: lvs. oblong-lanceolate, acuminate, finely and irregularly serrulate,  $2\frac{1}{2}$ -4 in. long: anthers yellow: fr. pink, turbinate, 4-lobed. Himalayas. Probably not in cult.; the plant cult. under this name is *E. Maackii*.—*E. lanceifolia*, Loes. Allied to *E. hians*. Shrub or tree, to 30 ft.: lvs. firm at maturity, lanceolate to elliptic-oblong, crenately serrulate, 3-6 in. long: anthers purple: fr. 4-lobed, pale; aril orange, open at the apex; seed crimson. Cent. and W. China.—*E. macroptera*, Rupr. Allied to *E. latifolia*. Lvs. obovate or obovate-oblong, cuneate at the base: cymes many-fl. fr. with 4 narrow wings  $\frac{1}{2}$ - $\frac{3}{4}$  in. long. Japan. N. E. Asia. I.T. 6:121. Hardy.—*E. occidentalis*, Nutt. Shrub, to 15 ft.: winter-buds rather large: lvs. ovate or elliptic-lanceolate, irregularly serrulate: fls. 5-merous, purple: fr. slightly lobed. Ore., Calif.—*E. oxyphylla*, Miq. Shrub or small tree: lvs. ovate or obovate, acuminate, rather large, serrulate: fls. 5-merous, purple or whitish: fr. globose. Japan.—*E. pendula*, Wall. (*E. fimbriata*, Hort.). Evergreen, small tree, with pendulous branchlets: lvs. oblong-lanceolate, sharply serrate, shining, 3-6 in. long: fr. with 4 tapering wings. P.F.G. 2:55. F.S. 7, p. 71.—*E. planipes*, Koehne. Allied to *E. latifolia*. Lvs. cuneate at the base; petioles flat, not grooved: fr. acutely 5-angled, scarcely winged. Japan. M.D. 1906, p. 62. Gt. 53, p. 29.—*E. sacchalnensis*, Maxim. Allied to *E. latifolia*. Lvs. ovate-oblong, crenate-serrulate: cymes very long-peduncled; fls. purple: fr. distinctly winged, convex at the apex. N. E. Asia.—*E. Sargentiana*, Loes. & Rehd. Evergreen shrub: lvs. obovate to oblong-obovate, abruptly acuminate, remotely crenate-serrate,  $2\frac{1}{2}$ -3 in. long: fr. oblong-obovoid, 4-angled. W. China.—*E. Semenovi*, Regel & Herd. Allied to *E. europaea*. Small shrub: lvs. lanceolate, serrulate: cymes usually 3-fl. fr. 4-lobed with obtuse lobes. Turkestan.—*E. semiserrata*, Koehne. Allied to *E. Maackii*. Lvs. oblong or oblong-lanceolate, crenate-serrate, 2-5 in. long: fr. light pink; aril orange, open, with the blood-red seed almost half exposed. Japan.—*E. Sieboldiana*, Blume. Allied to *E. Maackii*. Lvs. slender-petioled, elliptic to oblong, acuminate, serrulate: fr. not lobed, strongly 4-ribbed. Japan. M.D. 1906, p. 62. Not in cult.; the plants cult. under this name belong to *E. yedoensis*, *E. patens* or *E. Bungeana* var. *semipersistens*.

ALFRED REHDER.

**EXACUM** (classical name, of no significance to these plants). *Gentianaceæ*. Herbs treated either as annuals or biennials or perennials, with flowers of white, lilac, blue or dark purplish blue, cultivated in a very few greenhouses.

Very rarely suffrutescent: dwarf or tall and paniculate-branching: lvs. sessile, clasping or short-stalked, ovate or lanceolate, mostly 3-5-nerved: fls. small or attaining 2 in. across, rotate, pedicelled or not, in forking cymes,

calyx 4-5-parted, the segms. keeled, winged or flat and 3-nerved; corolla-lobes 4 or 5, ovate or oblong, twisted; stamens 4 or 5, attached to the throat, with very short filaments, the anthers opening by apical pores that finally enlarge nearly to the base: fr. a globose 2-valved caps.—Species about 30, in Trop. and Subtrop. Asia, Malaysia, Trop. Afr., Socotra.

Plants of *E. affine* flower in summer. If specimens in 5-inch pots are desired, sow in March of the same year; for larger specimens, sow in August of the preceding year. The plants must be kept in a cool but not draughty greenhouse or frame in summer, and shaded from fierce sunlight. They usually are given warmhouse conditions.

A. *Lvs. with stalks often ½ in. long.*

**affine**, Balf. St. cylindrical, 1-2 ft. high, much branched from the base: lvs. 1-1½ in. long, elliptic-ovate, faintly 3-5-nerved: sepals with a broad wing on the back; corolla 6-9 lines wide; lobes almost rounded. Socotra. B.M. 6824. A.F. 13:1104. Gng. 6:229. R.H. 1883, p. 512. Gt. 32:1108. G.C. II. 21:605.

AA. *Lvs. nearly or quite stalkless.*

B. *Corolla-lobes rounded.*

**zeylânicum**, Roxbg. Annual: st. 4-sided, branched only above: lvs. becoming 3 in. long, strongly 3-nerved, elliptic-oblong, acuminate, narrower than in *E. affine*, and tapering: fls. blue, 1½ in. across, in terminal, leafy corymbs; sepals broadly winged; corolla-lobes obovate, obtuse. Ceylon. B.M. 4423 (sky-blue, with a dash of purple). R.H. 1859, p. 238. J.F. 1:43. H.F. II. 2:60.

BB. *Corolla-lobes usually tapering to a point.*

**macrânthum**, Arn. (*E. zeylânicum* var. *macrânthum*). Fig. 1468. St. cylindrical, slightly branched: lvs. as in *E. zeylânicum*, though perhaps more variable from base to summit: fls. purplish blue, 2 in. across. In both species there is a narrow ring of yellow at the mouth, to which the conspicuous clusters of stamens are attached. Ceylon. B.M. 4771 (deep purplish blue). G.C. III. 15:331. R.H. 1911, p. 31. J.H. III. 42:182; 51:259.—The best of the genus. The rich, dark blue is worth striving for.

**Förbesii**, Balf. Bushy and shrubby: lvs. triangular or ovate-lanceolate, 1½ in. across at base: fls. upwards of ½ in. across, purple or violet-purple, in terminal racemes, the anthers yellow and prominent. Socotra. G.C. III. 31:93. G. 23:679. G.W. 6, p. 290. G.M. 45:81.—A good plant for intermediate temperature, blooming well in a 6-in. pot.

WILHELM MILLER.  
L. H. B.†

**EXCÆCÀRIA** (from Latin *excæcæres*, referring to its effect on the eyes). *Euphorbiacæ*. Tropical trees or shrubs with poisonous milky juice rarely cultivated for ornament.

Glabrous: lvs. alternate or opposite, usually entire (or crenate to serrate): infl. usually in axillary spikes; fls. dioecious or monœcious; calyx imbricate; sepals 2-3, free or connate at base; petals none; stamens 2-3, erect in bud; filaments free; ovary 3-celled, 3-ovuled: seed not canaliculate.—About 25 species in the Old World tropics. Related to *Stillingia* and *Sapium*.

**bicolor**, Hassk. (*Crôton bicolor*, Hort.), with the opposite lvs. red beneath is sometimes cult. for ornament in European greenhouses or outdoors in the tropics. *E. Agallocha*, Linn., **AGALLOCHA**, **BLINDING TREE**, **RIVER POISON**, etc., with alternate lvs., is a well-known poisonous tree of the coasts of S. Asia. J. B. S. NORTON.

**EXHIBITIONS** of horticultural products have been both a concomitant and a stimulant of progress in American horticulture. The great international expositions ushered in by the Centennial Celebration of 1876 at Philadelphia, through the opportunities afforded

for the comparison of products, have been the means of unusual education in the identification of varieties. No amount of descriptive literature can compare with this method of acquiring accuracy in naming and describing fruits, flowers, and vegetables.

The interest in these great exhibitions by the growers of soil products indicates a peculiarity of this class of producers. They are the ones to reap the smallest direct result, and yet they have always been willing to give freely of their productions to swell the volume of these great fairs and emphasize the possibilities of the localities in which they lived. They would even pay their own expenses to attend these fairs and explain to the world how they succeeded in growing such attractive things. No producers of the useful things of life will compare with the horticulturist in willingness to impart to his fellow the secrets of his

1468. *Exacum macranthum* (× ½).

success. National, state, district and township exhibitions have thus become great methods of disseminating information of value to the horticulturist—educators of the people.

For many years the most prominent feature of fruit shows was the nomenclature of the exhibit. In vegetables it was the size of the specimen, in flowers the number of sorts and their tasteful arrangement. People flocked together to identify varieties, to see the big things and to satisfy esthetic longing. Later the art in exhibiting products was given more attention, and wonderful creations have resulted from combinations and artistic arrangement.

Exhibitions have been the favorite opportunities of bringing out new and valuable sorts and often the usefulness of a variety dates from some particular fair at which it was prominently displayed. Notable instances of this were the grapefruit, which was shown in quantity for the first time at the great New Orleans exhibition; the Kieffer pear, which was a distinguishing

feature of a meeting of the American Pomological Society in Philadelphia; the Niagara grape, which was featured at a winter meeting of New York fruit-growers. Striking examples of this are found in the annals of floral exhibits. The dissemination of the most delightful strains of carnations and chrysanthemums dates from some particular fair or "show."

In recent years, the experiment stations of the country have added greatly to their usefulness in preparing technical exhibits for winter exhibitions of horticultural societies, helping their progressive work, through graphic illustrations of the results which they have obtained in growing products under varying conditions, and having in mind the demonstration of problems of value to growers.

One of the most recent developments has been the opportunity given students of agricultural colleges of putting into practice the knowledge of varieties which they have acquired in the naming of various collections as a competitive drill.

The products of glass farming have been brought into prominence through national, state, and local horticultural societies in their annual exhibitions, and the great seedhouses of the country have used these exhibitions as avenues for the dissemination of new and valuable varieties. Nurserymen have successfully utilized exhibitions in publishing to the world not only their new creations but their methods of propagation.

During recent years the initiative of the American Pomological Society has been followed by many other organizations in perfecting a scale of points for judging exhibits of horticultural products. By this means, more accurate methods have come into use at our great fairs, and, in the hands of experts, the judgments rendered have been far more satisfactory and useful.

A most important result of exhibitions has been the acquirement of the knowledge that varieties vary a great deal as the result of climatic conditions and differences in soil, and it is found as an outcome of these comparisons that certain localities are especially adapted to certain varieties in which they reach their highest perfection. This is illustrated in the Rocky Ford cantaloupe, the Albemarle Pippin, certain strains of carnations, and head lettuce. The facts brought out through these comparative exhibits are leading to scientific investigations concerning the conditions which produce these variations which will be of great use to the producers, as well as deep interest to the scientist.

Commercial problems are finding their solution through exhibitions which illustrate styles of packing and kinds of packages and general attractiveness in presenting the products to the consumer. Already these exhibitions have brought to the attention of law-makers the importance of uniform legal requisitions concerning methods of marketing throughout the land.

The most recent development of values resulting from horticultural exhibits of great utility has been the carrying of the methods of comparison instituted there to the growing of products on the farm and in the garden, orchard and vineyard, thus awakening a deeper interest in the factors which affect the production of horticultural creations and a recognition of the uses of these creations in landscape art. Thus an abiding interest has been awakened in the development of the science as well as the art of horticulture through the adoption of new and improved methods of production and widening the usefulness of the products.

CHARLES W. GARFIELD.

### Exhibitions of plants and flowers.

Floral exhibitions undoubtedly had their origin, in part, in the desire to display publicly the products of one's skill and to attain renown and a position of pre-

eminence among one's fellows by successful rivalry and the demonstration of superior cultural abilities. But, in addition to this factor of self-interest and excusable pride, the laudable spirit that seeks to promote a taste for ornamental gardening and floriculture in general, and to acquire knowledge and diffuse information concerning it, has from the first been a powerful incentive; and it cannot be questioned that public floral exhibitions have contributed most substantially to the advancement of refinement and good taste and exercised a potent and salutary influence on the domestic life, health, morals and happiness of the respective communities in which they have been held.

Exhibitions of plants and flowers, as usually conducted, may be broadly divided into two classes: (1) Those whose particular purpose is to demonstrate advancement in cultural methods and exploit new and improved varieties and which are calculated to interest primarily the trade and professional gardeners. The unavoidably monotonous system of staging exhibits in such an affair is well-known. To the general public, its salient points are scarcely apparent, and the elements which often appeal most strongly to the professional are all but lost on the average visitor. It has been demonstrated over and over again, that as an attraction for the people who look for entertainment in a show and are willing to pay for the privilege of seeing it, this sort of an array is fundamentally deficient. (2) If public support is sought, the first requisite is that the public fancy be considered and catered to and the character and scope of the exhibition be such as the people care to take an interest in. A practical demonstration of the uses of flowers and plants and their appropriate arrangement for the various events of social or home life will invariably excite curiosity and interest when prim rows of dozens and fifties of competitive blooms will often fail to awaken appreciative response. It is to be regretted that the so-called retail florist trade has so long been neglectful of its duty and its opportunity as a supporter of and participator in the flower shows. Without the assistance and coöperation of the experienced decorator and artistic worker in flowers, these affairs must invariably fall short of their mission and their educational possibilities. How to overcome the indifference of this branch of commercial floriculture toward these enterprises which should bring immeasurable benefit to their industry is one of the serious problems for which those who believe in flower shows must find a solution before the ideal of what a horticultural exhibition should be can be realized.

The direct cost of installing a public flower show is no small matter and many a commendable enterprise has failed through lack of sufficient income properly to finance it. Rent of hall, music, advertising, premiums, tables, vases, management, labor and a host of incidentals must be taken carefully into consideration, and to launch any such project, under conditions now existing, without some form of endowment, subscription, guaranty or other definite and reliable resource, apart from the uncertain sale of admission tickets, is merely tempting fate and taking chances on misfortune.

The grouping of pot-plants for effect calls for talents of a high order. Arrangements of this kind, which are so indispensable in giving character to a flower show that will appeal to the artistic eye as effective studies in form and color, are indeed rarely seen. Two almost universal faults are excessive formality in contour of the group and overcrowding of material, and it not infrequently happens that when a studied effort has been made for irregularity of outline, the result is still unnatural and often almost grotesque. The promiscuous mixing together of incongruous subjects, as, for example, hardy conifers, tropical palms, geraniums and orchids in one group, is all too common. A taste-

ful grouping of plants of congenial character will always inspire enthusiastic admiration among cultured and discriminating visitors, and if the flower pots are hidden from sight by moss or other natural material, the pleasing effect will usually be further enhanced, particularly in the case of plants which might naturally grow together.

It is well known among flower-growers that the time of day, the condition of development, and other factors have a considerable influence on the keeping qualities of their product. A sojourn in a cool, dark room over night with stems deeply immersed in fresh water is really an essential with many flowers if they are to remain for any time in good condition in the atmosphere of an exhibition hall. Nothing is more disfiguring in a flower show than a lot of wilted blooms. Much depends upon the style of vases used. Vases spreading at the top and narrowing to a point at the bottom, while perhaps the most graceful in form, are very destructive to flowers, the small quantity of water available at the base of the stems soon becoming heated and impure. Constant changing of water, and keeping down the temperature of the hall will help to preserve the exhibits. Table baskets and dinner-table exhibits generally, as often arranged, scarcely last until the first visitors are admitted. Only those in which the flower-receptacles are such as contain water can give any satisfaction in a flower show.

The background against which flowers are shown, as the color and material of the walls, covering of tables, and so on, has much to do with the general impression, favorable or otherwise, on the visitor. Green—the natural foliage green—is unquestionably the “middle of the road” background hue for flowers. Back of and beyond green, the neutral grays and browns, and sometimes pure white, are pleasing and satisfactory. It is worth noting that, while terra-cotta or flower-pot tones are usually beyond reproach as a background for living green, yet a brick wall is a disheartening condition for this purpose, showing that it is not alone color which decides the appropriateness of exhibition hall walls or drapery.

The number of specimens usually shown in cut-flower classes depends upon the kind of flowers, the ingenuity of the schedule-makers, and the demands of the occasion. The more extensive and pretentious the exhibition, the larger should be the classes. Roses and carnations in half-dozens, for example, have little value in a large exhibition. Fifties and hundreds alone will impress the visitors. When individual blooms, or groups composed of individual varieties are displayed, much depends upon the taste shown in color-arrangement. This is especially important with such subjects as chrysanthemums, dahlias, gladioli and sweet peas, all of which afford wide scope for demonstration of taste in exquisite blending, contrasting and gradation of color-tones, qualities which should count for much in the final decisions of the judges. The question of the height of tables or platforms on which flowers are shown is one which should be carefully considered in planning an exhibition. There are flowers which should be looked down upon if their full beauty is to be seen. Others must arch overhead to display their graces, and there are many intermediate steps. As a rule, exhibition tables are set too high.

One main reason for the flower show being its educational value, the proper and legible labeling of species and varieties is essential. In no other respect are our exhibitions so deficient. A neat label, attached so it can be read without handling, and legible at a fair distance, is something rarely seen at a flower show, while obtrusive advertising cards or award cards frequently spoil the beauty of an otherwise creditable staging.

Competitive exhibitions properly conducted and entered into with the right spirit are, as before said,

calculated to accomplish much good for the art of horticulture. Emulation in a friendly contest for honors is a strong factor in the success of a show, but the kind of rivalry which stimulates jealousies, envenoms disappointment and incites to angry protests over judges' decisions, is one of the most mischievous elements that can intrude upon the scene. In order to discourage the protesting habit and minimize the demoralizing influence of questionable decisions, great care should be exercised always in the selection of competent, disinterested and impartial judges. Their names should be announced a sufficient time in advance so that every intending exhibitor may know who is to pass upon his exhibits.

It is now a generally established custom to inclose the name of an exhibitor in an envelope bearing only the class number, the identity of the exhibitor not to be disclosed until after the judging has been completed. Some very excellent systems of cards, record books, envelopes, and so on for this purpose have been devised and are in general use.

WM. J. STEWART.

#### Exhibition of fruits. Fig. 1469.

The educational value of carefully planned exhibitions of fruits can scarcely be overestimated. That this fact is appreciated in increasing measure each year is demonstrated by the growing number of such exhibitions that are being held throughout the country. Commercial fruit regions do much of their advertising by means of these annual affairs, and there are few towns or hamlets, however unpretentious, without their yearly fruit show promoted by the grange, the school, the church, or some other organization whose aim is progress in country affairs.

Foresight, with careful attention to details, is essential if the possibilities of an exhibition are to be developed to the utmost. The larger number of such events are held in the fall, since fall is Nature's harvest season for fruits. This means that preparation must begin in midsummer to insure the greatest measure of success. There are many things that the grower can do at this time to secure high-class fruit for exhibition purposes, and no other should be considered.

The best fruit is often found near the top of the tree, if thorough spraying has been done. It is the best because conditions there are most nearly ideal for its development. As the fruit increases in size and the weight upon the branches becomes greater, the side branches settle more closely together, while the top-most branches and those most nearly upright in habit of growth, always advantageously situated, have an increased opportunity to receive the abundance of air and sunlight so essential to normal and perfect fruit. Fruit on such branches invariably possesses the highest color of any on the tree, and color is of vital importance for the matter in hand. The color may be heightened and the size increased if the fruit is thinned until the specimens hang 6 inches or more apart. A branch may be headed back, and occasionally one may be removed entirely to the benefit of those remaining, if good judgment is used. This matter of thinning is of considerable importance in the securing of high-class exhibition fruit, whether the fruit be apple, orange, or grape.

The production of exhibition specimens by abnormal processes—as by ringing or girdling—is not allowable, unless for the express purpose of showing what can be accomplished by such practices: fruits produced by such means should not be shown in comparison or competition with specimens produced under recognized and standard methods.

The specimens should be allowed to remain attached to the parent plant as long as possible. The longer they remain thus, the more intense will be their color and the greater will be their size. Pears especially

increase very rapidly in size just before maturity. The picking should be done by hand and with the greatest care. Many an excellent specimen has been ruined by careless handling. The stems should remain intact. The picker should remove, not a sufficient number of specimens to meet the requirements under which the exhibit is held, but many times that number. A bushel, or even a barrel, of seemingly high-class fruit will often yield after the most rigid inspection but a single plate of perfect specimens.

The actual selection of the specimens to be exhibited is the most difficult and perplexing problem connected with this work. Fundamental to a successful solution of this problem is a thorough knowledge of the variety, an intimate acquaintance with the characters of a normal specimen, and a fine discrimination in the balancing of these characters and in the attaching of the proper values to each.

The external factors that must be considered are size, form, color, uniformity, and freedom from blemishes. The criteria to be used in the inspection of the

1469. Good exhibition plates of apples.

first three factors are the attributes of a typical normal specimen of the variety when grown under conditions favorable to its development. The largest apple is not necessarily the best; in fact, great size is usually obtained at the expense of some equally desirable factor. The extra-large specimen is always an abnormal specimen and, as such, is not to be sought. It is in regard to this factor, however, that many exhibitors make their first mistake. A safe rule to follow is to choose the specimen combining large size with the highest color. This rule will almost invariably eliminate the abnormally large specimen.

The form of the specimen should be true to the prevailing type of the section in which it grows. Occasionally different sections produce different types, as, for example, the New York and the Oregon-grown Esopus. One is as true to type as the other, but the two types should never be mixed on the same plate or in the same package.

Of all external factors, none exceeds in importance the quality of color. High color always sets up in the mind the presumption of excellence; the higher the color, the more pronounced seems to be the presumption, though it is not always justified. Color is also an indication of fitness, of approaching maturity, but a specimen maturing far in advance of its companions should be regarded with suspicion lest it harbor a worm that may emerge at a most inopportune moment if it escapes detection. Polishing a specimen to enhance its color should not be practised. The operation removes the bloom, which is more beautiful than the high polish because it is natural.

The factor of uniformity implies that one specimen should resemble every other specimen as nearly as

it is possible for the human eye and hand to make it. It is a literal application of the expression "as nearly alike as two peas." A single specimen of highest order should not be retained for a moment if its companions are on a more nearly equal though somewhat lower plane of excellence.

Freedom from blemishes implies that the specimen is perfectly sound. A blemish may be anything from a bruise, a broken stem, or a stem puncture to a scale-mark or scab-spot. In an age when knowledge of preventive measures is so widespread and so accessible, evidence of injury from insect or disease should completely exclude a specimen from consideration. Needless to say, the condition of the specimen should be as sound as the season permits, showing neither flabbiness nor physiological disintegration of the tissues.

The factor of quality is also worthy of consideration, though it is of more importance in case of collections in which one variety is exhibited against another than in case of different specimens of the same variety. Granted that size, form, and color are normal, the factor of quality will usually take care of itself.

There is need of a standardization of requirements under which fruit exhibits are held. These requirements should be based on trueness to type and all that the term implies, and the values attached to the different characters concerned should be fixed in proportion to their relative importance for the purpose in hand. Such a statement appears in the following score-card for apples, which is in somewhat common use in the eastern United States:

|                             |     |
|-----------------------------|-----|
| Size.....                   | 10  |
| Form.....                   | 10  |
| Color.....                  | 20  |
| Uniformity.....             | 15  |
| Quality.....                | 20  |
| Freedom from blemishes..... | 25  |
| Total.....                  | 100 |

This score-card may be no more nearly correct than many others, but it represents a concerted effort to fix a satisfactory standard. There should be more of this work for every fruit.

Score-cards for other fruits have been adopted by particular exhibitions and institutions as the following for grapes:

|                           |     |
|---------------------------|-----|
| Form of bunch.....        | 10  |
| Size of bunch.....        | 15  |
| Size of berry.....        | 10  |
| Color.....                | 10  |
| Bloom.....                | 5   |
| Freedom from blemish..... | 20  |
| Flavor.....               | 25  |
| Firmness.....             | 5   |
| Total.....                | 100 |

There is need also of a general agreement as to the number of specimens to be exhibited on a single plate. The rules now governing all large exhibitions in the East require that plates of apples, peaches, pears, and quinces shall contain five specimens; of the smaller fruits a sufficient number to fill a 6-inch plate; and of grapes three clusters.

Fruit to be sent away for exhibition should be carefully packed. A bushel box is a satisfactory package for this purpose, being better than a larger package in which the pressure on the fruit is greater. Each specimen should be wrapped, and the box should be well lined with excelsior or other material. Extra specimens should be included to replace those that are injured in any way.

In selecting the room in which the exhibition is to be held and in setting up the fruit, one prime factor should always be kept in mind—there should be nothing in the room to detract in any way attention from the fruit. To this end, the walls should be plain or

even bare. The decorations should be few, simple, and in harmony with the colors of the fruit, that is, substantial and perfectly plain. Red and white make a very effective combination for ceiling decorations, if decorations seem desirable. Plain white is best for draping the tables. If electric lights are present, the shades may be covered with red crepe paper. This will give a quiet and subdued effect to the room when the lights are on and will be in keeping with the other decorations. The tables should be covered with a material that will throw the fruit into sharp relief without attracting attention to the covering itself. Oatmeal paper, gray-green in color, answers these specifications very well. Six- or eight-inch papyrus plates are better than smooth-pressed paper plates or the wooden plates and need no covering.

The fruit should be set up in such a way that a mass effect is produced, which impresses the observer with the fruit and with nothing else. This means that all the fruit must be on the same level. Shelves or tiers one above the other are not desirable. In other words, every detail should be subordinated to bringing out as sharply as possible the fruit that is on exhibition. It is therefore highly undesirable to place labels on the top of a specimen, as is so often done. The observer notes first of all a vast and meaningless sea of tags and after that perhaps the fruit. The label may be pinned into the plate in such a way that it is unnoticeable except on close inspection, when it can be plainly seen. A satisfactory label is a plain white card with three lines on it, the first for the variety name, the second for the name of the exhibitor when permissible, and the third for the section from which the fruit comes. If the exhibit is to attain its highest educational value, the varieties must be correctly named and the names correctly spelled.

In general, it will be better to group varieties together in order that comparisons may be made between the different plates. By so doing an opportunity is afforded for a study of variations of fruits grown under different methods of management and in different sections in which climatic conditions are unlike. Occasionally grouping by sections may be desirable, especially if there are general and marked contrasts between the same varieties as grown in different sections.

The plates should not be crowded on the tables lest the eye become confused and the fruit appear to be a jumble of specimens lacking orderly arrangement. The background of paper covering the table should be visible between every plate, not in order that it may be seen, but because it will serve to set off each plate as a separate unit meriting for the moment undivided attention.

Finally, the specimens should be arranged in the same order on every plate and the plates should be in perfect alignment in every direction. Not only this, but when the angles formed by the specimens on a plate are right angles, as in case of apples with four specimens on the bottom and one on top at the center, the angles should assume the same direction as those of the table top.

The same rules hold for the selection of fruit for barrels, boxes, or other packages as for single plates. The arrangement should be such as to bring out the fruit and subordinate the package, exemplified in the bank of boxed fruit.

C. S. WILSON.

#### Exhibition of vegetables.

The exhibition of vegetables is usually an important feature at county, district and state fairs, and often at farmers' institutes, horticultural society meetings and conventions of vegetable-growers. Vegetables are also likely to occupy a prominent place in county or state exhibits at state, national or international shows or expositions. The exhibits may be

competitive or non-competitive. In the former case they are usually made by the individual producers; in the latter case, they are more often made by a company, development bureau, or an institution, primarily for advertising or educational purposes. In either case, they have some educational value, even the individual exhibitor learning by comparison of his exhibit with others.

Competitive exhibits are of two kinds: (1) those in which the exhibit consists of a specified quantity of a given kind of vegetable, e.g., one dozen table carrots, and (2) those which consist of a collection or display of vegetables alone, or combined with other products of the soil. Vegetables in exhibits that are designed primarily for advertising or educational purposes usually form only a part of some general exhibit.

In making exhibits in competition with the products of other exhibitors, the successful competitors are usually those who give most careful attention to the selection, preparation and installation of their exhibits.

In making single exhibits, care should be taken to show the exact quantity or number of specimens mentioned in the entry list. At county fairs, especially, exhibitors are prone to make their "pecks" or "half-pecks" exceedingly small if exhibition material is scarce or time limited. The present tendency is to specify in premium lists the number of specimens, whenever this is feasible, rather than a given bulk, and to disqualify exhibits which do not conform to the requirement in this respect.

In selecting specimens which are to form a single exhibit, very few inexperienced persons appreciate the importance of uniformity in size and type. Sometimes an exhibit will be very creditable with the exception of one or two specimens. These odd specimens may be very good as individuals, but differ much in size or type from the other specimens and detract seriously from the value of the exhibit.

Vegetables on exhibition should be clean. Root crops should usually be washed. Onions are best prepared by careful brushing. Cauliflower and cabbage should be carefully trimmed; tomatoes, eggplant and melons wiped with a moist cloth. Celery, lettuce and endive should be gathered with the roots on, carefully washed, and displayed with the roots immersed in water so that the plants will not wilt.

The arrangement of the specimens in a single exhibit is also important. When the judging is by comparison, only those exhibits which attract the immediate attention of the judge will be likely to receive careful consideration if the number of entries is at all large. Under such conditions it often happens that the arrangement of the specimens is fully as effective in securing careful examination of the exhibit as is the perfection of the specimens themselves. In the case of many kinds of vegetables, if the number of specimens is not over one dozen, the exhibit can often be displayed very advantageously on plates or trays. If one peck or one-half bushel is prescribed, splint baskets are desirable receptacles. In any case, the appearance of the exhibition room will be greatly enhanced if the receptacles used for all the single exhibits are as uniform as the nature of the products will permit. With this end in view, it is desirable that the management furnish the receptacles.

In the exhibitions held by thoroughly established organizations which give special attention to vegetables, there is likely to be a recognized appropriate method of disposing the specimens of each kind of vegetable in or upon a given type of receptacle. At county fairs, each exhibitor usually exercises his own ingenuity both as to type of receptacle and method of arrangement; and the result is at least lacking in monotony. To show at its best, every exhibit should be characterized by neatness and simplicity in arrangement.

The principles involved in making a general display

including a number of different kinds of vegetables are much the same as for making individual exhibits: the specimens must be selected with care, thoroughly cleaned, and attractively arranged. In addition, the character and arrangement of the exhibit as a whole must be given careful attention. Very often, general displays fail in effectiveness because the number of specimens of each kind is too limited or the different specimens of the same kind are too much scattered through the exhibit, instead of being massed so that they would make an impression upon the spectator. Exhibitors are likewise inclined to weaken the character of an exhibit by introducing a few specimens each of numerous species or varieties that are little known or of small commercial importance. These are often scattered promiscuously through the exhibit and detract the attention from the main features. The general effect of the exhibit as a whole is of prime importance.

Non-competitive exhibits of vegetables for advertising or educational purposes are usually confined to a comparatively few species or varieties in a given exhibit. In exhibits made for advertising some particular section or locality, the vegetables are likely to be merely a minor part of a general exhibit, and to consist of specimens likely to attract attention by reason of their unusual size rather than any other noteworthy feature.

Certain kinds of vegetables lend themselves readily to the making of purely educational exhibits to illustrate the influence of differences in soil treatment or cultural methods or the results of treatment for plant diseases. In such exhibits, it is unwise to attempt to illustrate the results of many different treatments in one exhibit. It is much better to concentrate the attention of the spectator upon one or two striking results than to try to demonstrate a number of minor variations. If the latter method is attempted, the effectiveness of the display will be destroyed; for the passing observer recognizes only striking contrasts. For example, if a number of different fertilizer treatments have been employed, and all give marked results as compared with the check (the unfertilized plat), it would be unwise in an educational exhibit to attempt to illustrate the proportionate yields from all the treatments. Only the yields of the check plat and one or two others should be given. The casual observer can see three things at a glance, but not a dozen.

In making an educational exhibit to represent differences in yields, the quantities shown should represent yields from definite areas of ground, such as one-hundredth or one-thousandth of an acre; and the specimens should be arranged in such a way that the differences will be most apparent.

In arranging an exhibit to illustrate the results of treatment for plant diseases, e.g., treatment of seed potatoes for the control of scab, it is better to sort the specimens from each plat into "diseased" and "sound," and to display them in two contiguous piles, than to mix the diseased and sound promiscuously in the same pile.

The educational value of all exhibits, whether competitive or non-competitive, is greatly enhanced if careful attention is given to the proper labeling of the various parts or features of each exhibit. Conspicuous legends of a concise nature are of some benefit to even the casual observer, and are greatly appreciated by the few who are specially interested in the particular exhibit or the matter it is designed to illustrate. JOHN W. LLOYD.

**EXÓCHORDA** (from *exo*, external, and *chorde*, a cord, referring to the chord belonging to the external part of the placenta on the ventral side of the carpels). *Rosaceæ*. PEARL-BUSH. Ornamental shrubs grown chiefly for the showy racemes of pure white flowers.

Deciduous: winter-buds conspicuous, with imbricate

scales: lvs. alternate, petioled, entire or serrate: fls. in terminal racemes, polygamo-dioecious; calyx-tube broadly turbinate; calyx-lobes and petals 5; stamens 15–25, at the margin of a large disk, short; carpels 5, connate; styles distinct: fr. a 5-angled, deeply furrowed caps., separating into 5 bony, 1–2-seeded carpels; seeds winged.—Three species in China and Turkestan.

The pearl-bushes are slender-branched shrubs with rather thin bright green foliage and very showy white flowers. *E. Korolkowii* is hardy North. *E. racemosa* and *E. Giraldii* are at least hardy as far north as Massachusetts. They grow best in a well-drained loamy soil and in a sunny position. Propagation is by seeds, or by softwood cuttings taken from forced plants; taken in summer from the open they root slowly and with difficulty; also by layering.

**racemosa**, Rehd. (*E. grandiflora*, Lindl. *Amelanchier racemosa*, Lindl.). Fig. 1470. Slender spreading shrub, to 10, rarely to 15 ft., glabrous: lvs. elliptic to elliptic-oblong or oblong-obovate, entire or on vigorous shoots serrate above the middle,  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. long, whitish below; petioles about  $\frac{1}{2}$  in. long; racemes 6–10-fl.; fls. 2 in. across, pure white, short-stalked; petals roundish, clawed; stamens 15: fr. turbinate, about  $\frac{1}{2}$  in. long. April, May. China. B.M. 4795. F. S. 9:954. L.I. 11–12. Gt. 47: 1455. R.H. 1889, p. 128; 1896, p. 324, 325. J.H. III. 34:483; 53:285. G.C. II. 16:73; III. 7:613. Gn. 58, p. 315; 60, p. 232; 62, p. 161; 66, p. 141. A.F. 6:643. Gng. 5:97. F.E. 30:117; 31:971. G.M. 44:531. M.D.G. 1901:321; 1905: 254; 1906:561. G.W. 10, p. 430. H.F. 1867:250. Var. *prostrata*, Hort. A form with prostrate branches.—The species is among the showiest shrubs blooming in May.

**Giraldii**, Hesse (*E. racemosa* var. *Giraldii*, Rehd.). Similar to the preceding: lvs. oval or elliptic, entire, very rarely crenate-serrate; petiole about 1 in. long, usually red; fls. very short-stalked or nearly sessile; petals obovate, gradually narrowed into the claw, sometimes toothed; stamens 25–30. N.W. China. M.D.G. 1909:295. G.W. 16, p. 450. Var. **Wilsonii**, Rehd. (*E. racemosa* var. *Wilsonii*, Rehd.). Lvs. elliptic to oblong, occasionally serrate; petioles  $\frac{1}{2}$ – $\frac{3}{4}$  in. long, usually green: stamens 20–25. Cent. China.

**Korolkowii**, Lav. (*E. Albertii*, Regel. *E. grandiflora* var. *Albertii*, Aschers. & Graebn.). Upright, slender-branched shrub, to 12 ft., glabrous: lvs. oblong, to oblong-oblancoleate, obtuse or acute, gradually narrowed toward the base, entire, but the lvs. of the stronger shoots often serrate above the middle and at the base with 1 or few small narrow lobes,  $1\frac{1}{2}$ – $2\frac{1}{2}$  in. long; racemes 5–8-fl.; fls.  $1\frac{1}{2}$  in. across; petals narrowly obovate; stamens 25; caps.  $\frac{3}{4}$  in. long, ovoid, pointed. April, May. Turkestan. G.W. 16, p. 451. G. 31:505.—This is one of the earliest shrubs to burst into leaf in spring; it is of more upright habit and with

1470. *Exochorda racemosa* (×  $\frac{1}{3}$ )

darker and denser foliage than the preceding, but not so floriferous.

**macrántha**, Lemoine (*E. racemosa* × *E. Korolkóvii*). Similar to *E. racemosa*, but of more upright habit and more vigorous: lvs. generally obovate or oblong-obovate, bright green, entire on vigorous shoots crenate, 2-3 in. long: racemes 8-10-fld.; fls. 1¼-2 in. broad; petals obovate, narrowed into the claw; stamens about 20. April, May. Of garden origin. R.H. 1903, pp. 18, 64. M.D.G. 1902:484. G.W. 16:449.

**EXOGENIUM**: *Ipomæa*.

ALFRED REHDER.

**EXORRHIZA** (*exo*, out, outside, *rhiza*, root; alluding to the large aerial roots above the ground). *Palmæceæ*, tribe *Coccolineæ*. High-growing pinnate-leaved palm.

Stem or trunk straight, smooth, supported at the base by large aerial, spiny roots: lvs. large, pinnate. Allied to *Kentia*, but distinguished by the imbricate sepals of the staminate fls., the elongated subulate filaments of the stamens, by the roundish ovate sepals of the pistillate fls. and by the parietal ovule. In *Kentia* the ovule is basal and erect. Cult. as in *Kentia*. The following species flowered at Kew in 1901.

**Wendlandiána**, Becc. (*Kentia Exorrhiza*, Wendl.). Often more than 60 ft. high but in cult. reaching only 24 ft.: lvs. 10-12 ft. long; pinnæ alternately arranged, 1-2 in. from each other, becoming 4 ft. long and 2 in. broad, 8-10-nerved; spadix appearing below the lvs., enveloped in thick, coriaceous boat-shaped spathes; spadices 2, much longer than the spathes. Fiji Isls. B.M. 7797.

N. TAYLOR.†

**EXOSTÉMA** (name alludes to the exerted stamens). *Rubiaceæ*. Evergreen trees and shrubs of W. Indies and other parts of Trop. Amer., by some united with *Rustia*. There are upwards of 20 species. They are little known as warmhouse subjects, and the name does not appear in the trade. It is probable that the general treatment given *Cinchona* and similar things will apply to them. Lvs. opposite: fls. white, various in size and arrangement; corolla salver-form, the lobes 5 and spreading and narrow; stamens 5, inserted in the bottom of the corolla-tube, long-exserted; disk annular: fr. an oblong, cylindrical or club-shaped 2-valved caps. The fls. are commonly axillary or in terminal corymbs.

**EXPERIMENT STATIONS.** Every state of the Union, every island dependency of the United States, and every province of the Dominion of Canada has one experiment station for agriculture supported by public funds. A very few of the states have two stations, one being the regular federal agency in the state and the other being usually an institution established and maintained directly by the state and representing the movement that began before the passage of the federal experiment station act.

By the middle of the last century, the discussion for institutions or agencies to make experiments in agriculture was well under way. It was not till 1875, however, that any legislative body made an appropriation for the establishing of such an institution. This was in Connecticut. Other stations followed in several states, some of them under direct legislative enactment and others being organizations within colleges or college departments of agriculture. These movements were marked in North Carolina, New York, New Jersey, Ohio, Massachusetts, and other states. The movement in the United States for a national system of experiment stations took form in a bill for the purpose introduced into Congress in 1882 by Hon. C. C. Carpenter of Iowa. The bill finally to become a law was introduced in the House of Representatives by Hon. William H. Hatch of Missouri; this became law March 2, 1887, by the signature of President

Cleveland. It appropriates \$15,000 to each state for the purpose of establishing an agricultural experiment station, to be located at the land-grant college unless the state shall determine otherwise.

A second act, supplementing the Hatch Act, was approved March 16, 1906, by President Roosevelt, it having been introduced and carried to passage by Hon. Henry C. Adams, of Wisconsin. This appropriates \$15,000 to each state "for the more complete endowment and maintenance" of the stations, with the understanding and requirement that it shall support fundamental researches. About \$1,500,000 is therefore expended annually by the federal government for the maintenance of experiment stations in the forty-eight states, aside from similar grants for stations in Porto Rico and Hawaii, expenditures in the Philippines through the War Department, and in Alaska and Guam directly through the United States Department of Agriculture; and there is also a large and important expenditure in the Department of Agriculture itself, both for supervision and for investigation. The states also contribute heavily to the experiment station work. The total revenue in the United States for the year ended June 30, 1912 was \$4,068,240.09.

By law, reports are to be issued at least quarterly by the different experiment stations. These institutions are now issuing numerous bulletins, circulars and reports on an astonishing range of subjects and of the greatest importance to the people. The publications of the United States Department of Agriculture are very extensive and of the highest technical and general value.

In Canada, the experiment station movement was practically parallel with that in the United States. The Act for a dominion system was passed in 1886. One central station, or "central experimental farm," was established at Ottawa, and the stations in the provinces are branches of it and under the administration of its director. The grant of Parliament for the year 1913-1914 for the maintenance of the system of experimental farms was \$900,000.

In both the United States and Canada, horticulture is one of the important subjects of experiment and research. Usually this work is in charge of a separate officer, commonly known as a "horticulturist," and the number of associates and helpers may be several or many. The extent of horticultural research is now large and it is rapidly increasing. Persons desiring to be in touch with this work should apply to the experiment station in the state or province or to the national department; and a list of these institutions is given below. For further history and discussion of Experiment Stations in the two countries, see pp. 422-430, Vol. IV, Cyclo. Amer. Agric.

In the United States the address of the experiment station and of the college of agriculture is usually the same post-office. In New York, there is a state station at Geneva as well as the federal station and college at Ithaca; in Ohio, the experiment station is at Wooster, and the college is part of the State University at Columbus; in Georgia, the station is at Experiment and the college at Athens, in the University; in Connecticut, the federal station is at New Haven, and the college at Storrs; in other states the post-offices of the two are the same.

#### Canada.

The Dominion or headquarters institution is the Central Experimental Farm, Ottawa, Ontario.

#### Alberta.

Experimental Station, Lacombe.

Experimental Station, Lethbridge.

#### British Columbia.

Experimental Farm, Agassiz.

Experiment Stations, at Invermere, and at Sidney on Vancouver Island.

*Manitoba.*

Experimental Farm, Brandon.

*New Brunswick.*

Experimental Station, Fredericton.

*Nova Scotia.*

Experimental Farms, Nappan, Kentville.

*Ontario.*

Central Experimental Farm, Ottawa.

*Prince Edward Island.*

Experimental Station, Charlottetown.

*Quebec.*

Experimental Stations, Cap Rouge, Ste. Anne de la Pocatiere, Lennoxville.

*Saskatchewan.*

Experimental Farm, Indian Head.

Experimental Stations, Rosthern and Scott.

**United States.**

United States Department of Agriculture, Washington, D. C.

*Alabama.*

Agricultural Experiment Station of the Alabama Polytechnic Institute, Auburn.

Canebrake Agricultural Experiment Station, Uniontown.

Tuskegee Agricultural Experiment Station, Tuskegee Institute.

*Alaska.*

Alaska Agricultural Experiment Stations, Sitka, Kodiak, Rampart, and Fairbanks.

*Arizona.*

Agricultural Experiment Station of the University of Arizona, Tucson.

*Arkansas.*

Arkansas Agricultural Experiment Station, Fayetteville.

*California.*

Agricultural Experiment Station of the University of California, Berkeley.

*Colorado.*

Agricultural Experiment Station, Fort Collins.

*Connecticut.*

The Connecticut Agricultural Experiment Station, New Haven.

Storrs Agricultural Experiment Station, Storrs.

*Delaware.*

The Delaware College Agricultural Experiment Station, Newark.

*Florida.*

Agricultural Experiment Station of Florida, Gainesville.

*Georgia.*

Georgia Experiment Station, Experiment.

*Guam.*

Guam Agricultural Experiment Station, Island of Guam (address Island of Guam, via San Francisco).

*Hawaii.*

Hawaii Agricultural Experiment Station, Honolulu.  
Hawaii Sugar Planters' Experiment Station, Honolulu.

*Idaho.*

Agricultural Experiment Station of the University of Idaho, Moscow.

*Illinois.*

Agricultural Experiment Station of the University of Illinois, Urbana.

*Indiana.*

Agricultural Experiment Station of Indiana, La Fayette.

*Iowa.*

Iowa Agricultural Experiment Station, Ames.

*Kansas.*

Kansas Agricultural Experiment Station, Manhattan.

*Kentucky.*

Kentucky Agricultural Experiment Station, Lexington.

*Louisiana.*

State Experiment Station, Baton Rouge.

North Louisiana Experiment Station, Calhoun.

Rice Experiment Station, Crowley.

Sugar Experiment Station, Audubon Park, New Orleans.

*Maine.*

Maine Agricultural Experiment Station, Orono.

*Maryland.*

Maryland Agricultural Experiment Station, College Park.

*Massachusetts.*

Massachusetts Agricultural Experiment Station, Amherst.

*Michigan.*

Experiment Station of Michigan Agricultural College, East Lansing.

*Minnesota.*

Agricultural Experiment Station of the University of Minnesota, University Farm, St. Paul.

*Mississippi.*

Mississippi Agricultural Experiment Station, Agricultural College.

McNeill Branch Experiment Station, McNeill.

Delta Branch Experiment Station, Stoneville.

Holly Springs Branch Experiment Station, Holly Springs.

*Missouri.*

Missouri Agricultural College Experiment Station, Columbia.

Missouri State Fruit Experiment Station, Mountain Grove.

*Montana.*

Montana Agricultural Experiment Station, Bozeman.

*Nebraska.*

Agricultural Experiment Station of Nebraska, Lincoln.

*Nevada.*

Nevada Agricultural Experiment Station, Reno.

*New Hampshire.*

New Hampshire College Agricultural Experiment Station, Durham.

*New Jersey.*

New Jersey Agricultural College Experiment Station, New Brunswick.

New Jersey State Agricultural Experiment Station, New Brunswick.

*New Mexico.*

Agricultural Experiment Station of New Mexico, State College.

*New York.*

New York Agricultural Experiment Station, Geneva.  
Cornell University Agricultural Experiment Station, Ithaca.

*North Carolina.*

North Carolina Agricultural Experiment Station, West Raleigh.

Agricultural Experiment Station of the North Carolina State Department of Agriculture, Raleigh.

*North Dakota.*

North Dakota Agricultural Experiment Station, Agricultural College.

- Ohio.*  
Ohio Agricultural Experiment Station, Wooster.
- Oklahoma.*  
Oklahoma Agricultural Experiment Station, Stillwater.
- Oregon.*  
Oregon Experiment Station, Corvallis.

- Wyoming.*  
Wyoming Agricultural Experiment Station, Laramie.

#### Research in horticulture. (U. P. Hedrick.)

For the purposes of this discussion we need not concern ourselves with formal definitions of horticulture nor discuss its several divisions. (For definitions, see *Horticulture*.) It is more to the point to indicate the nature of the research problems to be solved in the several loosely correlated industries of which horticulture is composed. Experimenters in horticulture may investigate the phenomena of science, the mechanical methods of an art, and latterly they have come to have much to do with business affairs. What should be the relative status of science, art and business in research work in this branch of agriculture?

Horticulture is a "no man's land" in science. Botanists, chemists, entomologists, bacteriologists and geneticists, join in solving its problems. First one science and then another lets in its light and illuminates an obscure nook. Thus, systematic botany, in the classi-

fication of orchard and garden plants, began the construction of rational horticulture; then came chemistry to furnish knowledge of soils and fertilizers; botany and entomology brought aid in combating innumerable pests. When, however, a discovery is made in any science men are drawn to it as moths to a light, and botany and entomology, which have recently been most prominent, are now giving way in horticulture to genetics and the sciences having to do with the soil, discovery and activity being greatest in these fields. Thus, there is no science of horticulture, but there is science in horticulture. The science field, also, is as open to horticulturists as to experimenters in the sciences that form the foundation of horticulture.

The application of science is art. The botanist and entomologist discover the life-history of insects and fungi; the control of the pests, by means of spraying or otherwise, is an art. The discovery of the laws that govern soil-moisture and soil-heat is a field for the scientist; the art of tillage is or should be founded on the science of soil physics. A widely different phase of physics comes into action when the mechanical engineer is asked to help solve the problems of cooling, storing and transporting horticultural products. The manipulation of plants in propagating, grafting and training is an art based on plant physiology. Thus, research work in horticulture partakes of the "practical;" indeed, applicability usually must be a paramount consideration in investigations in this field. Much that is called "pure science" is helpful in horticulture, but the horticulturist is chiefly concerned with applied science.

So, also, there are inter-relations between business, science and art in horticulture. A prevalent phase of experimentation is the determination of the cost of the unit—the barrel of apples, for example—of agricultural products; other business experiments seek to determine the outgo and the income of the orchard and garden; still others consider the relative profits of two crops in certain soils or other environmental conditions. These problems are largely studies of business methods and are not true research subjects, but one can conceive of scientific investigations in the business affairs of horticulture and certainly science and business come into close touch in this industry.

The distinctions that have been made are not clearly defined in the activities of horticulturists. Too often men supposed to be engaged in research work in horticultural science are busy with the art—very often not in discovery or invention in art but simply with the details of well-established art. Much that is put out as the result of research work is a description or a discussion of the technic of horticulture. A study of business methods, pure and simple, is frequently offered as the results of research. These isolated observations on the art and business of horticulture, having no relation to either pure or applied science, ephemeral and of but limited application, bear but poorly the brand of investigation. Data in the art and business of horticulture, to be worth the while of the true research worker, must be a part of the coordinated and classified knowledge of horticulture, must be of more or less universal application, and must deal more or less directly with scientific principles. Investigating is not teaching, nor demonstrating, nor observing, nor describing, nor proving, unless primarily behind any of these is the design to discover laws.

On the other hand, much that passes as scientific investigation turns out to be theory made attractive by the rouge of speculation; or it is controversy for controversy's sake; not infrequently the offering of science is an old garment made over in a new style; or it is a small truth much adorned; sometimes the scientific offering but heralds a discovery which never appears. Pseudo-research is by no means confined to the practical phases of horticulture.

The writer does not overlook the body of good work being turned out by the American experimenters in horticultural lines, but this is not the subject of the present discussion.

#### *The training of research workers.*

The diverse character of experimentation in horticulture as set forth indicates somewhat the training that investigators in this field should have. It follows from the importance attached to science in horticulture, that thorough training in the sciences is imperative, but the distinctions here made indicate just as clearly that a person trained in the sciences and not in the art and business of horticulture is sadly handicapped. We may put down as the first essential in the mental equipment of the research worker, a broad and severe scientific training. The second essential is, perfect familiarity with garden, orchard and greenhouse plants and methods of handling their products. It is not sufficient that the horticultural experimenter know but the industry in which he may specialize. Knowledge of what is done in the greenhouse, for example, is indispensable to the experimenter with fruits, offering him suggestions at every turn. Whatever knowledge a man may possess of the needs and care of plants in any field of agriculture will be helpful in a specialized field. Perhaps the ability to correlate science and art should be put down as a third essential.

But at present chief emphasis must be laid on the scientific training. The art of horticulture is sufficiently well taught in agricultural colleges, and the money-earning value of an education is in most institutions over-emphasized. The atmosphere of practicums and money-making which prevails in most of our colleges is not one in which investigators are born and bred. Instead, for the proper training of a horticulturist there should be an atmosphere of investigation for investigation's sake, of sound learning, of appreciation of science not only in its applications but as pure science and for its disciplinary value. It is desirable, almost imperative, that one training to become a horticulturist should take a post-graduate course in which special attention may be devoted to the sciences and the problems of horticulture.

#### *Equipment for research.*

Less need be said about the material equipment for horticultural research than the mental make-up of the worker. The nation and the states have been free in the expenditure of money for experimental work. Not a few horticultural departments in the experiment stations of the country are over-equipped with land, buildings and laboratories—the things that money can buy. Certain it is that the output from the institutions conducting research is not in proportion to the money spent or to the number of men on the staff. The fact that equipment and materials do not create, needs emphasis everywhere in horticultural experimentation. The custom of obtaining money to build up a department without specific work to be done is a vicious one from which there must in time be a reaction. Opportunity, equipment and problem should go together, and all these are valueless without a man with initiative, ideas, and training to use them. There are probably more over-equipped departments in horticulture than under-equipped ones. Large experimenting is sometimes small experimenting and small experimenting large experimenting.

In one particular, however, the horticultural departments of the country are sadly under-equipped. There are no comprehensive plantations of economic plants in the experiment stations of the United States. The amelioration of plants is the chief work in horticulture and it would seem that the establishment of economic gardens is imperative, since material to be used advantageously must be near at hand. At least one station

in every distinct agricultural region in the country should have an economic garden where may be found the food plants of the world suitable for the region. This should be an agricultural garden, not a plant museum to show the curious and the ornamental; in it agriculture must be dominant, not recessive.

#### *Organization for research.*

Horticulture is composed of so many industries and involves so many sciences that its problems are too diverse and too complex to permit of many definite statements in regard to organization for research. But several generalities may be set down as essentials to a good organization: (1) There must be a man in command—a broadly trained man. (2) The position of the experimenter should be permanent, subject only to efficiency. (3) The time and thought of the investigator must not be taken up with other activities, as administration, teaching, extension work and the like. (4) The organization must be permanent, to give continuity, coherence and exhaustiveness to the work. (5) The organization should usually correspond with the subdivisions of horticulture rather than the sciences upon which it is founded. That is, there should be pomologists, gardeners and florists, rather than botanists, chemists and entomologists. (6) Money and effort should be concentrated upon a few comprehensive problems that can be exhaustively carried to sound conclusions. Too many experiments are but fragments of a larger problem; discovered to be such, they are often discarded after waste of time and money.

The third of the essentials just given needs amplification. The greatest deterrent to good work in experimentation is the association of research with teaching either in the classroom or from the institute platform. So much of the time and energy of men having these dual-purpose positions is taken by the more present, and therefore more pressing, work of teaching that they are often investigators only in name. In every institution where teaching and investigating are combined, the demand is naturally strongest from students, and investigation suffers. There are, it is true, advantages in the combined position of teacher and investigator, but few indeed are the cases in which the disadvantages do not outweigh them and always the research work suffers.

There should be coöperation between the horticultural experimenters in the several states and the United States Department of Agriculture. A most pathetic spectacle in our agricultural institutions is that of isolated men attacking one and the same problem, duplicating results, often duplicating errors and in either case wasting public funds. So far as possible there should not be overlapping of experimental work, unless duplication is desirable to make more certain the results. In the latter case the work should be jointly planned and from time to time compared and adjusted to secure efficiency and economy. The Society for Horticultural Science is an excellent clearing-house in which the official horticultural experimenters in North America may interchange ideas and adjust their work.

Theories in horticulture are so general, facts so numerous, evidence of one kind or another so easily adduced, that the temptation is strong to state a theory, supply facts from the many already known, adorn the work with a dash of personally collected evidence and call the result an experiment. Such work lacks coherence and is incomplete. Few, indeed, are the horticultural investigators who make their work invincible by exhaustiveness. Again, the urgent call for results has led to the study of problems admitting of hurried conclusions rather than those that are fundamental, and for this reason much work is unfinished and inconclusive. The superb exhaustiveness of Darwin's work, much of it horticultural experimentation, should furnish inspiration and method to investigators in this

field of agriculture in particular. All call to mind that the "Origin of Species" is but a short statement of the theory of evolution which is then shown to be an impregnable fact by a vast amount of evidence over which Darwin labored for twenty years, biding time until his views reached full maturity. There is every temptation to publish prematurely, but permanent work is that which is completely worked out. Besides, given time, investigation is easier, material coming of itself which, under speed, would have required travail of mind to bring forth.

#### *The immediate field.*

In conclusion it may be well to state, as a record of the times, and for possible suggestive value, some of the present problems of horticulture.

Experimentation is needed in the oldest of horticultural operations—pruning. It must be approached through physiological botany. We know next to nothing about the feeding of plants and the influences of the food elements on plant-products—current methods of fertilizing are largely arbitrary. Many questions having to do with sex are before us. There is need of more precise knowledge about bud-formation and the setting and dropping of fruits. There is yet much to be done in the classification and description of horticultural plants. More than elsewhere in agriculture, horticultural plants are inter-planted as in catch-crops, cover-crops and in crop-rotation; the inter-relationships of plants and the effects of crop residues, therefore, must be studied. Greater knowledge of the associations of plants would throw new light on the relations of climates and soils to plant-growing—plant ecology. We have not yet reached the limit of improvement in any cultivated species and plant-breeding must be given attention. The relationships of parasites and hosts involving the whole matter of predisposition, resistance and immunity offer a series of problems. The good and bad effects of sprays, quite aside from their insecticidal or fungicidal functions, are worthy of study. Much has been written but very little is really known about the reciprocal influences of stock and graft. The whole matter of stocks needs experimental attention, fruit-growers in particular having little to guide them in the choice of stocks for the several fruits. We know that cultivated plants vary greatly: are any of the variations heritable or do they appear and disappear with the individual? A study of the last problem would bring one to a much-needed investigation of mutations. Acclimatization deserves consideration. There yet remain many native plants worthy of domestication. Forcing of plants brings up many problems; as, the influence of heated soils and atmospheres, soil sterilization, artificial lights in place of sunlight, the use of electricity in forcing growth and the physiological disturbances of the plant brought about by the changed environment. Lastly, those who ship and store horticultural products are calling for experimental aid to solve their many problems.

#### EXTENSION TEACHING IN HORTICULTURE.

Extension work is the effort made by an institution of higher learning to carry outside its own walls and directly to the people, any form of helpful educational influence. A state university, or institution that derives financial support from the state, may legitimately be called upon to give instruction to the people who cannot attend its courses, if means are provided for the performance of this office. Such an institution no longer fulfils its complete function when it confines itself to teaching students who come to it and to the investigation of problems within its laboratories. A strong college of arts and science, necessarily the center of the great university of today, may extend its educational ideals and its higher educational functions to the people of the state as well as to the students who

reside within it. The professional schools of law, medicine, education, engineering, journalism, agriculture and others (articulated with the college of arts and science, to make up the university) are each investigating the problems of their respective fields and gathering information that may be carried to the people of the state, through organized extension work. More and more the people are coming to depend upon this information as a basis for better enactment, better municipal functions, better sanitation, better regulations as to health, better civic improvement of all phases, and last, but not least, better agriculture, better roads, and a higher plane of country life.

Extension work in horticulture is that phase of organized extension activity that has to do with better production, better handling and better marketing of horticultural products and the higher efforts of living to which this work contributes.

Horticultural extension is conducted by means of private letters, lectures, publications, correspondence courses, demonstration schools, demonstration experiments, and the like.

*Private correspondence.*—Every fruit-grower, gardener, florist or other horticultural worker may encounter special problems upon which he needs individual advice. The horticultural department in any of our leading colleges of agriculture is called upon to answer thousands of letters of inquiry every year. Each of these inquiries is referred to the member of the horticultural staff best qualified to handle it. Many of these inquiries entail special letters. Some of them may be more fully answered by sending circulars or bulletins.

*Publications.*—Departments of horticulture disseminate much information through bulletins, circulars of information and press notices. These bulletins are the published results of the investigation of special problems by the members of the horticultural staff. Circulars of information are more popular treatises of horticultural subjects of interest in the state, and pertaining to which the department has gathered information of interest. Press notices are usually timely topics or seasonal advice furnished the press of the state to publish at the opportune time for their readers. If an insect or disease appears suddenly and promises to become widespread, due to unusual conditions, it often may be checked by prompt action. Unusual weather conditions may sometimes call for unusual methods of management of plants or of crops.

The publication may take the form of an organized reading-course effort without assuming to construct and conduct correspondence courses.

*Extension lectures.*—Hundreds of lectures on horticultural topics are given by members of the horticultural staff, at schools, teachers' meetings, civic improvement societies, commercial club meetings, nurserymen's conventions, canners' associations, fruit-growers' organizations, florists' clubs, and other gatherings. In this way something of the work of the Department may be carried to every organized body in the state which is interested in a phase of horticulture.

*Surveys.*—That the department of horticulture may be of special service to a horticultural center, or special horticultural industry, a careful survey of the horticultural conditions as they exist may be desirable. Such a survey may determine what varieties are proving most profitable, which of the prevailing methods of management are yielding the most satisfactory results, what are the difficult problems that need investigation and what are the reasons for successes or failures. The average result may throw much light upon what is already proving best in the neighborhood. A question that is vexing the average grower may have been answered by the work of the best growers, whose results show the answer to the question. As an example of the plan and possibilities of such surveys may

be mentioned the orchard survey of some of the leading apple-growing counties of New York. A measure of the commercial value of spraying is secured by statistical results from sprayed and unsprayed orchards. The commercial value of orchard tillage as compared with orchards growing in sod is shown by the returns from each class of orchard. The best methods of greenhouse construction and management for particular crops may be determined and explained in the same way.

*Extension schools.*—In many states, extension schools of horticulture are held for the purpose of carrying special horticultural instruction to a neighborhood. Such schools often consist of lectures and demonstrations in a subject of immediate interest. For example, just previous to harvesting a fruit crop a school in fruit-packing may be held. The methods and advantages of proper packing are presented by means of lectures. This is followed by practical laboratory periods in which those in attendance learn to do the work of proper packing. In a similar way, pruning, spraying and other phases of fruit-production are being taught in brief periods of one or two days or a week, the time varying with the needs of the community and the character of the subject taught; or situations with vegetable-growers and florists may be met.

*Correspondence courses.*—Some schools teach courses in horticulture by correspondence. Certain subjects are capable of being taught in this way. Outlines for the lessons are mailed to the student. Prescribed reading is required and directions for observations and original work and study of plants are formulated. Examinations usually consist of written reports made by the student, embodying a statement of the results secured by him. These reports usually show whether or not the student has grasped the subject and wherein he may need further suggestions and study.

*Boys' and girls' clubs.*—A movement that is destined to have a very profound influence is the organization of boys' and girls' clubs for the study of subjects relating to horticulture. Often this club work takes the form of contests in gardening or in the production of some special garden crop, such as tomatoes. Organization is best effected through cooperation with the schools or somebody that can direct the work of each local club. Printed sheets are mailed the club members, from time to time, giving instruction in the details of the work and the conditions governing the contest. Prizes are usually awarded at the local contests and sometimes the prize-winners compete in a state contest.

*Coöperative demonstrations and experiments.*—A very efficient means of promoting the productive growth of any horticultural interest is by means of coöperative demonstrations conducted on the grounds of some energetic grower, whose conditions fairly represent the neighborhood. The ground may be leased by the institution or offered by the local grower. Experiments are carefully outlined to test some problem of interest, such as spraying, comparison of methods of pruning or of cultivation or planting, the use of fertilizers, determination of the merits of particular flowers or vegetables, or other question which the community needs to have worked out. A representative of the horticultural staff visits the grounds as often as is necessary to oversee proper conduct of the work and to record the results of the experiment. Whenever results are secured that are of benefit to the growers, a meeting is held for the purpose of explaining and observing these results and demonstrating the methods for the benefit of those who may profit by adopting them. This form of extension affords the means not only of presenting to the grower facts and methods already known, but it also works new problems out for the neighborhood by securing results that are adapted to their special local requirement. It makes the work convincing; the growers themselves have a hand in it and feel that it is their own; they grow into

an understanding of it as the work grows; it gives a new pride and a new power in working for superior methods. While this is perhaps the most productive form of extension work, its scope is, of course, necessarily limited by the fact that working force and funds are not available for handling more than a limited number of the pressing problems in a state at one time.

*General considerations.*—Incidentally there are other ways by which extension work may be accomplished. Enough already has been accomplished to show that organized extension work has a large and increasing influence upon the horticulture of a state.

Like any other great movement in behalf of human progress, the measure of success of extension work in horticulture depends largely on its proper organization. It offers a multitude of opportunities for work that the world needs to have done. As indicated above, the work is approached in numerous ways. Unless properly organized there is danger of scattered effort, duplication, and failure to follow up results so as to give stability and permanence. It should be a factor in the organized extension work of the entire institution of which it is a part. The question then arises as to whether the work should be undertaken by a separate corps of workers, especially trained for the purpose, and acting under the direction of an extension department head, or whether, since it relates to a special professional field, it should be carried by the officers of the department of horticulture in the college and experiment station. To the writer, the latter seems to be the more rational arrangement. It is no doubt true that if a corps of men do extension work exclusively, with no definitely organized relation to college teaching and experiment station investigation, there will be a tendency to lose touch with higher educational ideals and failure to take to the people the stimulus of productive investigation and the last word in scientific advancement. Undoubtedly there is a tendency, especially on the part of younger men who have the faculty of appealing to the popular audience, to become satisfied with the plaudits of the multitude, and to strive only to enthuse and amuse, unless they are closely connected with college and station work. While one function of extension work may be to inspire and exhort, the day has passed when that alone is sufficient. The commercial horticulturist has reached a plane of development when he needs definite helpful instruction. Attractive letters and lectures are no longer sufficient. He needs, in addition, so far as it is possible to supply it, definite demonstrations of how to do his work according to the most approved methods. The men most closely in touch with strong college teaching and station investigation should be the best fitted to supply this need.

Furthermore, the college teacher or investigator equally needs intimate contact with the commercial grower and his problems. His problems are the problems of the teacher and the investigator. The above conclusions do not dispute the fact that an individual may have especial talent and taste for extension work and lack the plodding patience to make a strong investigator. He may largely devote his time to extension if only the organization keeps him closely linked with college and station men. On the other hand, a productive investigator may not best succeed as a popular lecturer and may give most of his time to investigation. His help may be indispensable in solving some of the difficult problems that arise in the field of extension. The organization of the individuals doing college and station work, ought to afford that union of relationship that will enable the director of extension to call the department of horticulture to his aid. The organization within the department should be best able to supply this need by calling upon the individual best fitted to meet the specific demand.
